1623. The table from which the above has been reduced to English measures, is extended to pieces of 31-980 in. square, and 47-97 ft. long; but as such scantlings rarely if ever occur in practice, unless strengthened by means of trussing, we have not considered it necessary to proceed beyond the scantling of 20-25 in. by 21-320 in., and 32 ft. long.

1624. Though the table is founded upon experiments on oak, it will serve for all sorts of wood, whose primitive strength is known, and the proportion they bear to oak. In order to facilitate calculations of that nature, the following table has been constructed, in which will be found the absolute and primitive strengths of the several sorts of timber, ordinarily used in carpentry, as also of some few others.

TABLE VII.

For applying the preceding Table to the Woods undermentioned. The primitive horizontal or transverse Strength of Oak is taken at 1000; its supporting or primitive vertical Strength at 807; and its cohesive or absolute Strength at 1821; being deduced from Pieces 19-188 lines English square.

Species of Wood.	Primitive horizontal Strength.	Primitive vertical Strength.	Absolute Strength.	Species of Wood.	Primitive horizontal Strength.	Primitive vertical Strength.	Absolute Strength.
Acacia (yellow)	780	1228	1560	Fir	918	851	1250
Ash	1072	1112	1800	Oak	1000	807	1821
Beech	1032	986	2480	Pine-tree	882	804	1141
Birch	853	861	1980	Poplar	586	680	940
Cedar	627	720	1740	Service-tree	965	981	1642
Cherry tree	961	986	1912	Sycamore	900	968	1564
Chestnut	957	950	1944	Yew-tree	1037	1375	2287
Elm	1077	1075	1980	Walnut	900	753	1120

*Method of using the above Table for horizontal Timbers.*

1625. To find the strength of a beam of fir 23·98 ft. long and 5·330 by 9·594 in. Against these dimensions in the Table VI. we find 10378 as the breaking weight. In the Table VII. we find the primitive horizontal strength of oak is to that of fir as 1000 to 918. Hence  $1000 : 918 :: 10378$  to a fourth term which = 9527; which expresses the greatest strength of such a beam of fir, or that which would break it. Cutting off the last figure on the right hand, that is, taking one tenth, we have 952 for the greatest weight with which such a beam should be loaded.

1626. If the beam be of chesnut, whose primitive strength is 957, the proportion becomes  $1000 : 957 :: 10378 : 9931$  = the greatest strength of such a piece, and  $\frac{9931}{10}$  the greatest weight with which it should be loaded.

*Method of Application for the vertical bearing Strength.*

1627. To find the vertical strength of an oak post 9·594 in. square, and 9·594 ft. high, we shall find in Table VII. for the primitive vertical strength, 807 for 19·188 lines English superficial. But as this strength diminishes as the relative height of the post increases, which in this case is 12 times, we must (1601.), take only  $\frac{5}{6}$  of 807, according to the progression there given, that is, 672 $\frac{1}{2}$ .

1628. The post being 9·594 in. square, its area will be  $9\cdot594 \times 12^2 = 13254\cdot756$ , and  $\frac{13254\cdot756}{19\cdot188} = 692\cdot34$ , and  $692\cdot34 \times 672\cdot5 = 465000$ , which divided by 10 = 46500; is the weight with which without risk the post may be loaded.

1629. If the post be of fir, whose primitive vertical strength to that of oak is as 851 to 807, we have only to use the proportion  $807 : 465000 :: 851 : 490980$ , which divided by 10 = 49098; the greatest weight with which it should be loaded.

*Method for obtaining the absolute or cohesive Strength.*

1630. In respect of this species of strength, which is that with which timber resists being drawn asunder in the direction of its fibres by weights acting at its ends, it is only necessary to multiply the area of the section of the piece reduced to lines by the tabular number 1821. if it be oak, and divide the product by 19·188, and the quotient will show the greatest effort it can bear.

1631. Thus for a piece of oak 9·594 in. square, we have  $\frac{13254\cdot75 \times 1821}{19\cdot188} = 1260700$  (in round numbers), which divided by 10 gives the greatest weight that should be suspended to the piece.

1632. From Table VII. it will be seen that in the direction of the absolute strength, beech is the strongest wood, and that strength will be  $\frac{13254\cdot75 \times 2480 \text{ (the tabular number)}}{19\cdot188} = 1363850$ , which will give 136385 for the greatest weight to be attached.

*Of the Strength of Timbers in an inclined Position.*

1633. If we suppose the vertical piece AB to become inclined to the base, experiment proves that its strength to resist (*fig. 614.*) a vertical effort diminishes as its inclination increases; so that, if from the upper part in D a vertical Df be let fall, and from the points of the base the horizontal line BC be drawn, the strength of the piece diminishes as Bf increases: whence, I. The strength of a vertical piece is to that of an inclined piece of the same length and scantling as the length AB is to Bf, or as the radius is to the sine of the inclination of the piece. II. Vertical pieces have the greatest strength to resist a weight, and the weakest are pieces which lie horizontally.

1634. The first of these results furnishes an easy method of finding, by the aid of the last table, the strength of a piece B of timber whose length and inclination are known. Thus, suppose a piece of oak inclined 4·692 feet and 9·594 feet long; its size being 8·528 by 9·594 inches, whose area, therefore, is 11781·74 lines. This must be divided by the tabular number 19·188, and the quotient will be 614. In table VII., 807 is the primitive vertical strength of oak for 19·188 lines superficial of section; but as the piece is more than 12 times the width of its base, we are, as before observed, to take only  $\frac{5}{6}$  of 807, or 672·5, which is to be multiplied by 614, and the product is 412915. Then the proportion  $9\cdot594 : 4\cdot692 :: 412915 : 843400$  is the strength, which, divided by 10 = 84340, is the greatest load to which the inclined piece ought to be subjected.

1635. In a section of a following chapter, that on PRACTICAL OR CONSTRUCTIVE CARPENTRY, tables of scantlings for timbers will be given, more immediately useful to the practical architect than those deducible from the above rules.

Fig. 614.

## CHAP. II.

## MATERIALS USED IN BUILDING.

## SECT. I.

## STONE.

1636. It is not our intention to advert to the stone which the Continent affords for building purposes; a knowledge of the different kinds there found would be of no use to the English architect, and would occupy too much of our space as mere information. It is almost superfluous to say that the choice of stone for a building intended to be durable is of the very highest importance. "In modern Europe," it has been observed, "and particularly in Great Britain, there is scarcely a public building, of recent date, which will be in existence a thousand years hence. Many of the most splendid works of modern architecture are hastening to decay in what may be justly called the infancy of their existence, if compared with the date of public buildings that remain in Italy, in Greece, in Egypt, and the East."

1637. The various sorts of stone take their names either from the places where they are quarried or from the substances which principally enter into their composition. The term "Freestone," which is used in a very arbitrary way, is, as its name implies, that sort which can be wrought with the mallet and chisel, or cut with the saw, an operation which cannot be performed upon granite, whose hardness requires it to be dressed with pointed tools of different weights and sizes. It includes the two great general divisions of Limestone and Sandstone. The limestone of Portland is that which has for many years past been chiefly used in the metropolis. Latterly, other sorts have found their way in from the provinces; and though, from many circumstances, we do not think it likely that Portland stone, from its facility of transport and other causes, will be altogether superseded, there is no doubt that its use is on the wane from the introduction of provincial sorts.

1638. We shall proceed, after some preliminary observations, to give, from the Report lately addressed to the Commissioners of Woods and Forests, on the occasion of selecting the stone for building the new Houses of Parliament, a view of the principal sorts of stone found and used in the island.

1639. The qualities requisite for a building stone are hardness, tenacity, and compactness. It is not the hardest stone which has always the greatest tenacity or toughness; for limestone, though much softer, is not so easily broken as glass.

1640. The decay and destruction of stone are accelerated by nearly the same causes as those which destroy rocks themselves on the surface of the globe. Such causes are of two kinds: those of decomposition and those of disintegration. The former effects a chemical change in the stone itself, the latter a mechanical division and separation of the parts. The effects of the chemical and mechanical causes of the decomposition of stone in buildings are much modified, according to their situation, as, in the town or country. In populous and smoky towns the state of the atmosphere accelerates decomposition more than in those placed in the open country.

1641. "As regards the sandstones that are usually employed for building purposes, and which are generally composed of either quartz or siliceous grains, cemented by siliceous, argillaceous, calcareous or other matter, their decomposition is effected according to the nature of the cementing substance, the grains being comparatively indestructible. With respect to limestones composed of carbonate of lime, or the carbonates of lime and magnesia, either nearly pure or mixed with variable proportions of foreign matter, their decomposition depends, under similar circumstances, upon the mode in which their component parts are aggregated, those which are most crystalline being found to be the most durable, while those which partake least of that character suffer most from exposure to atmospheric influences.

1642. "The varieties of limestones termed Oolites (or Roestones) being composed of oviform bodies cemented by calcareous matter of a varied character, will of necessity suffer unequal decomposition, unless such oviform bodies and the cement be equally coherent and of the same chemical composition. The limestones which are usually termed 'shelly,' from being chiefly formed of either broken or perfect fossil shells cemented by calcareous matter, suffer decomposition in an unequal manner, in consequence of the shells, which, being for the most part crystalline, offer the greatest amount of resistance to the decomposing effects of the atmosphere.

1643. "Sandstones, from the mode of their formations, are very frequently laminated,

more especially when micaceous, the plates of mica being generally deposited in planes parallel to their beds. Hence, if such stone be placed in buildings with the planes of lamination in a vertical position, it will decompose in flakes, according to the thickness of the laminæ; whereas, if it be placed so that the planes of lamination be horizontal, that is, most commonly upon its natural bed, the amount of decomposition will be comparatively immaterial.

1644. "Limestones, such at least as are usually employed for building purposes, are not liable to the kind of lamination observable in sandstones; nevertheless, varieties exist, especially those commonly termed *shelly*, which have a coarse laminated structure, generally parallel to the planes of their beds, and therefore the same precaution in placing such stone in buildings so that the planes of lamination be horizontal, is as necessary as with the sandstones above noticed.

1645. "The chemical action of the atmosphere produces a change in the entire matter of the limestones, and in the cementing substance of the sandstones according to the amount of surface exposed to it. The mechanical action due to atmospheric causes occasions either a removal or a disruption of the exposed particles, the former by means of powerful winds and driving rains, and the latter by the congelation of water forced into or absorbed by the external portions of the stone. These effects are reciprocal, chemical action rendering the stone liable to be more easily affected by mechanical action, which latter, by constantly presenting new surfaces, accelerates the disintegrating effects of the former.

1646. "Buildings in this climate are generally found to suffer the greatest amount of decomposition on their southern, south-western, and western fronts, arising doubtless from the prevalence of winds and rains from those quarters; hence it is desirable that stones of great durability should at least be employed in fronts with such aspects.

1647. "Buildings situated in the country appear to possess a great advantage over those in populous and smoky towns, owing to lichens, with which they almost invariably become covered in such situations, and which, when firmly established over their entire surface, seem to exercise a protective influence against the ordinary causes of the decomposition of the stone upon which they grow.

1648. "As an instance of the difference in degree of durability in the same material subjected to the effects of the atmosphere in town and country, we may notice the several frusta of columns and other blocks of stone that were quarried at the time of the erection of St. Paul's Cathedral in London, and which are now lying in the island of Portland, near the quarries from whence they were obtained. These blocks are invariably found to be covered with lichens, and although they have been exposed to all the vicissitudes of a marine atmosphere for more than 150 years, they still exhibit, beneath the lichens, their original forms, even to the marks of the chisel employed upon them, whilst the stone which was taken from the same quarries (selected, no doubt, with equal, if not greater, care than the blocks alluded to) and placed in the cathedral itself, is, in those parts which are exposed to the south and south-west winds, found in some instances to be fast mouldering away. Colour is of more importance in the selection of a stone for a building to be situated in a populous and smoky town, than for one to be placed in an open country, where all edifices usually become covered, as before stated, with lichens; for although in such towns those fronts which are not exposed to the prevailing winds and rains will soon become blackened\*, the remainder of the building will constantly exhibit a tint depending upon the natural colour of the material employed.

1649. "Before we proceed to adduce a few examples of the present condition of the various buildings we have examined, we would wish to observe that those which are highly decorated, such as the churches of the Norman and pointed styles of architecture, afford a more severe test of the durability of any given stone, all other circumstances being equal, than the more simple and less decorated buildings, such as the castles of the fourteenth and fifteenth centuries, inasmuch as the material employed in the former class of buildings is worked into more disadvantageous forms than in the latter, as regards exposure to the effects of the weather; and we would further observe, that buildings in a state of ruin, from being deprived of their ordinary protection of roofing, glazing of windows, &c., constitute an equally severe test of the durability of the stone employed in them.

1650. "As examples of the degree of durability of various building stones in particular localities, the following may be enumerated. Of the sandstone buildings which we examined, we may notice the remains of Ecclestone Abbey, of the thirteenth century, near Barnard Castle, constructed of a stone closely resembling that of the Stenton quarry in the vicinity, as exhibiting the mouldings and other decorations, even to the dog's-tooth ornament, in excellent condition. The circular keep of Barnard, apparently also built of the same material, is in fine preservation. Tintern Abbey may also be noticed as a sandstone

\* We must take leave to question this statement; as, for instance, in St. Paul's Cathedral we find the northern front peculiarly black, whilst the south front and south-western angle are comparatively white. This we have always considered to have arisen from the more constant action of the sun's rays upon them.

edifice that has to a considerable extent resisted decomposition; for although it is decayed in some parts, it is nearly perfect in others. Some portions of Whitby Abbey are likewise in a perfect state, whilst others are fast yielding to the effects of the atmosphere. The older portions of Ripon Cathedral, constructed of sandstone, are in a fair state of preservation. Rivaulx Abbey is another good example of an ancient sandstone building in a fair condition. The Norman keep of Richmond Castle in Yorkshire affords an instance of a moderately hard sandstone which has well resisted decomposition.

1651. "As examples of sandstone buildings of more recent date in a good state of preservation, we may mention Hardwicke Hall, Haddon Hall, and all the buildings of Craigleith Stone in Edinburgh and its vicinity. Of sandstone edifices in an advanced state of decomposition we may enumerate Durham Cathedral, the churches at Newcastle upon Tyne, Carlisle Cathedral, Kirkstall Abbey, and Fountains Abbey. The sandstone churches of Derby are also extremely decomposed; and the church of St. Peter at Shaftesbury is in such a state of decay that some portions of the building are only prevented from falling by means of iron ties.

1652. "As an example of an edifice constructed of a calciferous variety of sandstone, we may notice Tisbury Church, which is in unequal condition, the mouldings and other enrichments being in a perfect state, whilst the ashler, apparently selected with less care, is fast mouldering away.

1653. "The choir of Southwell Church, of the twelfth century, may be mentioned as affording an instance of the durability of a magnesio-calciferous sandstone, resembling that of Mansfield, after long exposure to the influences of the atmosphere.

1654. "Of buildings constructed of magnesian limestone we may mention the Norman portions of Southwell Church, built of stone similar to that of Bolsover Moor, and which are throughout in a perfect state, the mouldings and carved enrichments being as sharp as when first executed. The keep of Koningsburgh Castle, built of a magnesian limestone from the vicinity, is also in a perfect state, although the joints of the masonry are open in consequence of the decomposition and disappearance of the mortar formerly within them. The church at Hemmingborough, of the fifteenth century, constructed of a material resembling the stone from Huddlestone, does not exhibit any appearance of decay. Tickhill Church, of the fifteenth century, built of a similar material, is in a fair state of preservation. Huddlestone Hall, of the sixteenth century, constructed of the stone of the immediate vicinity, is also in good condition. Roche Abbey, of the thirteenth century, in which stone from the immediate neighbourhood has been employed, exhibits generally a fair state of preservation, although some portions have yielded to the effects of the atmosphere.

1655. "As examples of magnesian limestone buildings in a more advanced state of decay, we may notice the churches at York, and a large portion of the Minster, Howden Church, Doncaster Old Church, and others in that part of the country, many of which are so much decomposed that the mouldings, carvings, and other architectural decorations are often entirely effaced.

1656. "We may here remark, that, as far as our observations extend, in proportion as the stone employed in magnesian limestone buildings is crystalline, so does it appear to have resisted the decomposing effects of the atmosphere; a conclusion in accordance with the opinion of Professor Daniell, who has stated to us that from the results of experiments, he is of opinion 'the nearer the magnesian limestones approach to equivalent proportions of carbonate of lime and carbonate of magnesia, the more crystalline and better they are in every respect.'

1657. "Of buildings constructed of oolitic and other limestones, we may notice the church of Byland Abbey, of the twelfth century, especially the west front, built of stone from the immediate vicinity, as being in an almost perfect state of preservation. Sandysfoot Castle, near Weymouth, constructed of Portland oolite in the time of Henry VIII., is an example of that material in excellent condition; a few decomposed stones used in the interior (and which are exceptions to this fact) being from another oolite in the immediate vicinity of the castle. Bow and Arrow Castle, and the neighbouring ruins of a church of the fourteenth century, in the Island of Portland, also afford instances of the Portland oolite in perfect condition. The new church in the island, built in 1766, of the variety of the Portland stone termed *roach*, is in an excellent state throughout, even to the preservation of the marks of the chisel.

1658. "Many buildings constructed of a material similar to the oolite of Ancaster, such as Newark and Grantham Churches, and other edifices in various parts of Lincolnshire, have scarcely yielded to the effects of atmospheric influences. Windrush Church, built of an oolite from the neighbouring quarry, is in excellent condition, whilst the Abbey Church of Bath, constructed of the oolite in the vicinity of that city, has suffered much from decomposition; as is also the case with the cathedral, and the churches of St. Nicholas and St. Michael in Gloucester, erected of a stone from the oolitic rocks of the neighbourhood.

1659. "The churches of Stamford, Ketton, Colley Weston, Kettering, and other places

in that part of the country, attest the durability of the Shelley oolite, termed *Barnack Rag*, with the exception of those portions of some of them for which the stone has been ill-selected. The excellent condition of those parts which remain of Glastonbury Abbey show the value of a shelly limestone similar to that of Douling, whilst the stone employed in Wells Cathedral, apparently of the same kind, and not selected with equal care, is in parts decomposed. The mansion, the church, and the remains of the abbey at Montacute, as also many other buildings in that vicinity, constructed of the limestone of Ham Hill, are in excellent condition. In Salisbury Cathedral, built of stone from Chilmark, we have evidence of the general durability of a siliciferous limestone; for, although the west front has somewhat yielded to the effects of the atmosphere, the excellent condition of the building generally is most striking.

1660. "In the public buildings of Oxford, we have a marked instance both of decomposition and durability in the materials employed; for whilst a shelly oolite, similar to that of Taynton, which is employed in the more ancient parts of the cathedral, in Merton College Chapel, &c., and commonly for the plinths, string-courses, and exposed portions of the other edifices in that city, is generally in a good state of preservation, a calcareous stone from Heddington, employed in nearly the whole of the colleges, churches, and other public buildings, is in such a deplorable state of decay, as in some instances to have caused all traces of architectural decoration to disappear, and the ashler itself to be in many places deeply disintegrated.

1661. "In Spofforth Castle we have a striking example of the unequal decomposition of two materials, a magnesian limestone and a sandstone; the former employed in the decorated parts, and the latter for the ashler or plain facing of the walls. Although the magnesian limestone has been equally exposed with the sandstone to the decomposing effects of the atmosphere, it has remained as perfect in form as when first employed, while the sandstone has suffered considerably from the effects of decomposition.

1662. "In Chepstow Castle, a magnesian limestone in fine preservation, and a red sandstone in an advanced state of decomposition, may be observed, both having been exposed to the same conditions as parts of the same archways; and in Bristol Cathedral there is a curious instance of the effects arising from the intermixture of very different materials, a yellow limestone and a red sandstone, which have been indiscriminately employed both for the plain and decorated parts of the building; not only is the appearance in this case unsightly, but the architectural effect of the edifice is also much impaired by the unequal decomposition of the two materials, the limestone having suffered much less from decay than the sandstone.

1663. "Judging, therefore, from the evidence afforded by buildings of various dates, there would appear to be many varieties of sandstone and limestone employed for building purposes which successfully resist the destructive effects of atmospheric influences; amongst these the sandstones of Stenton, Whitby, Tintern, Rivaulx, and Cragleith, the magnesian-siliciferous sandstones of Mansfield, the calciferous sandstone of Tisbury, the crystalline magnesian limestones, or *Dolomites* of Bolsover, Huddlestone and Roche Abbey, the oolites of Byland, Portland, and Ancaster, the Shelly oolites and limestones of Barnack and Ham Hill, and the siliciferous limestone of Chilmark appear to be amongst the most durable. To these, which may all be considered as desirable building materials, we are inclined to add the sandstones of Darley Dale, Humble, Longannet, and Crowbank, the magnesian limestones of Robin Hood's Well, and the oolite of Ketton, although some of them may not have the evidence of ancient buildings in their favour." The Report upon which we have drawn so largely, and from which we shall extract still larger drafts, then proceeds to close by a preference to limestones on account "of their more general uniformity of tint, their comparatively homogeneous structure, and the facility and economy of their conversion to building purposes," of which it prefers the crystalline; on which account, and its combination with a close approach to the equivalent proportions of carbonate of lime and carbonate of magnesia, for uniformity in structure, facility and economy in conversion, and for advantage of colour, the parties to the Report prefer the magnesian limestone or dolomite of Bolsover Moor and its neighbourhood. The Report deserves every commendation. There are points which, were we disposed to cavil, might furnish matter for it, but upon the whole it has been well done, and is the first scientific step the government of this country has ever taken in respect of practical architecture.

1664. The following table presents a synoptical, and, to the architect, important view of the relative value, in every respect, of the principal species of stone which the various provinces of England afford for building purposes, and is condensed from the Report so much at length above quoted.

## SANDSTONES.

Name of Quarry, and where situated.	Proprietor of Quarry.	Component Parts of Stone.	Colour.	Weight of a Cubic Foot in its ordinary State.	Weight of Block, and the Thickness procurable.	Price per Cubic Foot at the Quarry.	Price per Cubic Foot, delivered in London.	Where used.
				lb. oz.			s. d.	
ABERCARNE and NEWBRIDGE, near Newport, Monmouthshire	Sir B. Hall, Bart.	Quartz and siliceous grains, moderately fine, with argillo-siliceous cement; micaceous, and with remains of fossil plants	Dark bluish grey.	167 15 1	to 10 tons, in thicknesses of 5 feet.	4d., or 5s. per ton	1 5	Old churches and modern buildings in vicinity; new Docks at Newport and Cardiff.
BALL CROSS	-	Siliceous grains with argillo-siliceous cement; occasionally micaceous, ferruginous.	Ferruginous brown striped, and zoned in deeper tints.	- -	- -	- -	- -	At Chatsworth and Bakewell.
BARBADOES, Tintern, Monmouthshire.	Duke of Beaufort.	Fine and coarse quartz, and other siliceous grains, with argillo-siliceous cement, ferruginous spots, and plates of mica.	Light greyish brown.	146 12 1	to 10 tons, thickest bed 10 to 12 ft.	10d. to 1s.	- -	Tintern Abbey.
BINNIE, Uphall, and in Linlithgowshire.	Earl of Buchanan.	Fine quartz grains, with argillo-siliceous cement, micaceous, chiefly in planes of beds.	Brownish grey.	140 1	Bands 14 to 18 ft. thick (3 in number).	1s. 1d. to 2s. for largest blocks.	2 9 3 8	New club-house in Prince's Street, Edinburgh, and numerous private houses there and in Glasgow.
BOLTON'S QUARRY, Aislaby, Yorkshire.	Messrs. Elgie and Lawson, as executors of the late Mr. Noble, of York.	Moderately fine siliceous grains, with argillo-siliceous cement, plates of mica, and spots of carbon disseminated.	Warm light brown.	126 11	100 ft. cube; top beds for house building, bottom beds for docks. Beds 3 to 8 ft. thick.	10d. to 1s.	1 9 2 1	Whitby Abbey, New University Library at Cambridge, Scarborough and Bridlington Piers, Sheerness and St. Katharine's Docks, &c.
BRAMLEY FALL (Old Quarry), near Leeds, Yorkshire.	Earl of Cardigan.	Quartz grains (often coarse), and decomposed felspar, with argillo-siliceous cement. Mica rare. Small ferruginous spots disseminated.	Light ferruginous brown.	142 3	Up to 18 tons.	- -	- -	In numerous bridges, waterworks, &c.
CALVERLEY, Tunbridge Wells, Kent.	John Ward, Esq., Holwood Park, Bromley, Kent.	Fine siliceous grains, with a slightly calcareous cement.	Variegated browns.	118 1	70 or 80 ft., and upwards to 500. Beds to 3½ ft.	4d. to 6d.	1 2 to 1 4	Upper part of new church at Tunbridge Wells; Catholic Chapel, the Calverley Hotel, new Market House, and Victoria National School, and about 100 houses, &c., at Tunbridge Wells and its vicinity.

PORTLAND (VERN-STREET QUARRY), Island of Portland.	Messrs. Weston.	Oolitic carbonate of lime, with a few fragments of shells.	Whitish brown.	134 10 top bed.	Any practicable size.	1 4½	2 3	Various public buildings in London.
PORTLAND (CASTLE'S QUARRY), Island of Portland.	Messrs. Weston.	Oolitic carbonate of lime, with a few fragments of shells.	Whitish brown.	- -	Any practicable size.	1 4½	2 3	Various public buildings in London.
PORTLAND (WAYCROFT QUARRIES), Island of Portland.	The Crown, on lease to Messrs. Stewards and Co.	Oolitic carbonate of lime, with disseminated fragments of shells.	Whitish brown.	135 8 top bed.	Any practicable size.	1 4½	2 3	Goldsmiths' Hall, Reform Club House, and other public buildings in London.
PORTLAND (MAGGOTT QUARRY).	The Crown, on lease to Messrs. Stewards and Co.	Oolitic carbonate of lime, with fragments of shells.	Whitish brown.	- -	Any practicable size.	1 4½	2 2	Various public buildings in London.
PORTLAND (GOSLING'S QUARRY).	Messrs. Stewards and Co.	Oolitic carbonate of lime, with fragments of shells.	Whitish brown.	126 13 Roach	Any practicable size.	1 4½	2 3	Several public buildings in London.
PORTLAND (GROVE QUARRY BOWERS).	Messrs. Stewards and Co.	Oolitic carbonate of lime, with numerous fragments of shells.	Whitish brown.	147 10 best bed. 145 9 carf.	Any practicable size.	1 4½	2 3	St. Paul's Cathedral, and several churches in London, built during the reign of Queen Anne.
PORTLAND (GROVE QUARRY, REDCROFT).	Messrs. Stewards and Co.	Oolitic carbonate of lime, with a few fragments of shells.	Whitish brown.	- -	Any practicable size.	1 4½	2 0	St. Paul's Cathedral, and many churches in London, of Queen Anne's reign.

Of the Portland stones, it is to be observed generally, that the dirt bed is full of fossil roots, trunks, and branches of trees, in the position of their former growth. The top cap is a white, hard, and closely compacted limestone. The skull cap is irregular in texture, and is a well-compacted limestone. The roach beds are always incorporated with the freestone beds, that invariably lie below them, and are full of cavities formed by the moulds of shells and the like. The top bed is the best stone, the bottom one ill cemented, and will not stand the weather. A middle or curf bed occurs only in the north-eastern part of the island; it is soft to the north, and hard to the south. The good Portland stone, of which the top bed is generally less in depth than in the same bed in the west of the island, is harder, more especially to the south of the island. The stone, even in the same quarries, varies considerably. That which contains flints will not stand the weather. The bottom bed on the west cliff is not a durable stone, though sold as a good stone in the London market. The best stone is in the north-eastern part of the island; the worst in the south-western part. The annual consumption of the whole of the quarries in the island is equal to an area of one acre of the good workable stone, or about 24,000 tons. The entire area unworked is about 2000 acres. There are 56 quarries in the island, and about 240 quarrymen employed, of which number Messrs. Stewards employ usually about 138.

WASS, near Thirsk, Yorkshire.	Martin Stapleton, Esq.	Compact carbonate of lime, with oolitic grains and an argillous - calcareous cement; carbon disseminated.	Brown.	141 11 soft. 162 8 hard.	Beds variable, with oolite about 16 in.	- -	- -	West front and a large proportion of Byland Abbey.
WINDRUSH, near Burford, Gloucestershire.	Lord Shelburne.	Fine oolitic grains, with calcareous cement, and a few fragments of shells.	Cream.	118 25 soft. 135 15 hard.	to 40 ft. Thickest bed, 2 ft 6 in.	0 8	2 7	Windrush Church, Barrington House, and all the old buildings within many miles of the quarry.

1665. The following very useful enumeration of the stones used in buildings of the island, arranged under that head, and divided into the sorts of stone employed in them, we add, *verbatim*, from the Report which we have so much used. The heads are under SANDSTONE buildings, LIMESTONE buildings, and MAGNESIAN LIMESTONE buildings

## SANDSTONE BUILDINGS.

BAKEWELL, Derbyshire. The houses generally are of sandstone, and in fair condition. A new bank now erecting of sandstone from Bakewell Edge.

BAKEWELL CHURCH (14th century), of a sandstone of the vicinity, very much decomposed.

BARNARD CASTLE, Durham (14th century). Circular keep, apparently of Stenton stone, in excellent condition. In modern works, the Joint Stock Bank and Market-house of Stenton stone, in good condition.

BELPER NEW CHURCH, Derbyshire. Built 10 years since, of sandstone from Hungerhill, in an incipient state (in parts) of decomposition.

BLANDFORD PARISH CHURCH, Dorsetshire (1769). Of a green siliceous fine-grained sandstone, the dressings being of a stone similar to the Portland oolite; the former much decomposed; the latter in very good condition. Town Hall, about 80 years old, of stone similar to the Portland oolite, in good condition.

BRANCEPETH CASTLE, Durham. Of ancient date, of sandstone of the vicinity; recently restored extensively; older parts in various states of decomposition.

BRIAVEL'S, ST., CASTLE, Gloucestershire. In ruins (13th or 14th century). Entrance gateway (the chief remains of the castle) built of red sandstone, decomposed.

BRISTOL CATHEDRAL (13th and 14th centuries). Built of red sandstone and a yellow limestone (magnesian?) strangely intermixed; the red sandstone in all cases decomposed, the limestone more rarely decayed; the tracery, &c. of the windows, which are of the limestone, are in good condition; but the pinnacles and other dressings, which are of the same material, are much decomposed. The east end of the cathedral is a remarkable instance of the decay and preservation of the two stones employed. Norman gateway, west of the cathedral (the upper part of the 15th century); the Norman archway and its enrichments, which are of a very florid character, built of yellow limestone (magnesian?), in excellent condition.

BYLAND ABBEY (12th century). In part of a siliceous grit (principally in the interior), and in part (chiefly on the exterior) of a compact oolite, from the Wass quarries in the

- vicinity. The west front, which is of the oolite, is in perfect condition, even in the dog's-teeth and other florid decorations of the doorways, &c. This building is *covered generally* with lichens.
- CARLISLE. Ancient buildings: Cathedral (13th century), of red sandstone, in various states of decomposition. Modern buildings: Many of red sandstone, more or less in a state of decomposition.
- CASTLE HOWARD, Yorkshire. Built generally of a siliceous fine-grained sandstone from the park; generally in good condition, but in some parts, such as the parapets, cupolas, and chimney shafts, much decomposed. The pilasters of the north front from a quarry at Appleton; in good condition, except where subjected to alternations of wet and dry, as in the plinths, where there are signs of decomposition. The stables are of Appleton stone, and in good condition.
- CHATSWORTH HOUSE, Derbyshire. Original house built of Bell Crop sandstone from Bake-well Edge, not in very good condition, particularly in the lower parts of the building. In the recent additions the same stone is employed, together with that of Bailey Moor and Lindrop Hill.
- CHEPSTOW CASTLE, Monmouthshire (11th and 12th centuries, with additions of the 14th century). Of mountain limestone and old red sandstone; the former in good condition; the latter decomposed. Dressings of doors, windows, archways, and quoins are for the most part of magnesian limestone, in perfect condition; the remainder is of red sandstone, and is generally much decomposed. Chapel (of the 12th century); mouldings and carvings of the windows, &c., which are of magnesian limestone, are in perfect condition.
- COXWOLD CHURCH, Yorkshire (15th century). Generally of fine siliceous grit of the vicinity, and in part of a calcareous nature. Tower in good condition; porch decomposed; lichens abundant on the north side.
- DERBY. St. Peter's Church (13th century), of the variegated coarse sandstone of the vicinity, similar to that of Little Eaton. The whole in bad condition; but the red stones less so than the grey or white. St. Almund's Church (of the 14th century), of a coarse sandstone of the vicinity, in a very decomposed state, to the obliteration of the mouldings and other details; it has lately been scraped and painted, to preserve it from further destruction. All Saints Church (tower of the 15th century), of sandstone, similar to that of Duffield Bank, partly in fair condition, and partly much decomposed, particularly the great western entrance. The body of the church, built 110 years since, of sandstone, in part decomposing. Modern buildings: Town Hall, of sandstone from Morley Moor, built a few years since, in very good condition.
- DURHAM CATHEDRAL (11th and 12th centuries). Of a sandstone of the vicinity, elected indiscriminately, and in all stages of decomposition; few stones are quite perfect. CASTLE (of the 11th century). Of similar stone, and in a similar state.
- EASBY ABBEY, Yorkshire (13th and 14th centuries). Of sandstone of the vicinity; mouldings and carvings decomposed and in part obliterated. Walls built very rudely, and in various states of decomposition; some parts, however, maintain their original surface.
- ECCELESTON ABBEY, Yorkshire (13th century). Of stone similar to that of the Stenton quarry. The mouldings and other decorations, such even as the dog's-teeth enrichments, are in perfect condition.
- EDINBURGH. Ancient buildings: Holyrood Chapel (12th century), of sandstone from the vicinity, in part much decomposed; in other parts, such as the west door, almost perfect. The palace (built in the 16th and 17th centuries) of similar stone, generally in good condition, the older parts being slightly decomposed. The oldest part of the Tron Church (1641), of sandstone, much decomposed. A house on the Castle Hill (1591), of sandstone, only slightly decomposed.
- Modern buildings, wholly erected of sandstones from the Cragleith, Red Hall, Humbie, and Binnie quarries, for the most from the first-mentioned quarry. None of them exhibit any appearance of decomposition, with the exception of ferruginous stains, which are produced upon some stones. Among the oldest is the Registry Office, which is of Cragleith stone, and built above sixty years since; it is in a perfect state.
- FOUNTAIN'S ABBEY, Yorkshire (11th and 12th centuries, with additions of the 16th century). Of coarse sandstone of the vicinity, generally in bad condition, particularly the west front, which is much decomposed. The nave and transept, which are the earliest portions of the building, are the best preserved.
- FOUNTAIN'S HALL, Yorkshire (1677). Of sandstone of the vicinity, and magnesian limestone in the dressings. The whole in fair condition.
- FOREST OF DEAN, Gloucestershire. Park End new church, built fifteen years since, of sandstone, similar to that of Colford. No appearance of decomposition.

**GLASGOW.** Ancient buildings: High Church (12th century), sandstone of the vicinity, generally very much decomposed, particularly on the south side. Old quadrangle of the College (James II.), of sandstone, decomposed.

Modern buildings: Hunterian Museum (1804); superstructure said to be of stone from the President quarry; slight traces of decomposition on the south-west front. The basement of another sandstone, in a more advanced state of decomposition; other parts of the building are in an almost perfect state. The other buildings are generally erected of stone from the Giffneuch and other quarries in the immediate neighbourhood, except the new Exchange buildings, which are of stone from the Humble quarry, thirty miles from Glasgow, recently erected, in which there are not any apparent symptoms of decomposition.

**GLOUCESTER CATHEDRAL** (Norman for the greater part, altered and cased in the 15th century), built of a fine-grained and ill-cemented oolite, a shelly oolite, and a red sandstone (north side) intermixed, of which the former constitutes the greater portion. The tower (15th century), of shelly oolite, in perfect condition. The early turrets of the south transepts are also in good condition. The body of the building is much decomposed. The great cloister is built of the same materials as the cathedral. The moulded and decorated work is in good condition, the other parts are more or less decomposed. The small cloister is built of a fine oolite with a compact cement, and is in good condition. **THE NEW BRIDGE**, of Whitchurch sandstone, parapets of Ruordean fine-grained sandstone, in good condition.

**HADDON HALL**, Derbyshire (15th and 16th centuries). Of a fine-grained sandstone, similar to that of Lindrop Hill. The dressings, parapets, chimney shafts, quoins, &c. are wrought and rubbed; the remainder of the walls is of rough walling. The whole in fair condition.

**HARROWGATE**. Cheltenham Pump Room, of sandstone from Woodhouse, near Leeds. Built recently. In good condition. Swan Hotel and other modern buildings, of a coarse sandstone of the vicinity; generally in good condition.

**HARDWICKE HALL**, Derbyshire. (1597). Of a fine-grained sandstone, chiefly from a quarry in the hill on which the house is built, intermixed with a calciferous grit, similar to that of Mansfield; generally in good condition. The ashler is in parts decomposed, especially where it is set on edge.

**HOWDEN CHURCH**, Yorkshire (15th century); partly of magnesian limestone, of a deep yellow colour, and partly of a coarse siliceous grit, of a ferruginous colour. Dressings and enrichments and the central tower are of the former stone; generally decomposed, particularly at the top of the tower. The other parts of the building, which are of the grit, are very much decomposed.

**KIRKSTALL ABBEY**, Yorkshire (11th century). Of coarse sandstone of the vicinity, in various stages of decomposition according to the aspect. The east side is in fair condition; some of the zig-zag enrichments and early capitals and other enrichments of mouldings are in perfect condition. The windows of the chancel and tower (inserted in the 16th century) of a yellow sandstone, are for the most part gone, and what remains is much decomposed.

**MANSFELD TOWN HALL**, Nottinghamshire. Built three years since, of magnesio-calciferous sandstone from Mansfield: no appearance of decomposition.

**NEWCASTLE-UPON-TYNE.** Ancient buildings: St. Nicholas' Church (14th century), of sandstone of the vicinity, similar to that of the Heddon Quarry, very much decomposed. Parts restored within the last century, with the same stone, now decomposing. The upper part of the tower and spire restored within the last five years, and painted to preserve the stone from decay. Other ancient buildings, of the same stone, more or less in a state of decomposition, according to the date of their erection.

Modern buildings, built within the last 25 years, of sandstone from the Felling and Church quarries at Gateshead and the Kenton quarry: parts already show symptoms of decomposition.

**PONTEFRAC T CASTLE**, Yorkshire (14th century). Built generally of a coarse grit, of a dark brown colour, occasionally mixed with an inferior magnesian limestone. The whole in a very decomposed state, more particularly the sandstone, in which all traces of the original surface are effaced. Fragments of magnesian limestone are embedded in several parts of the walls, with mouldings of the 12th century, in perfect condition.

**RABY CASTLE**, Durham (14th century). Of sandstone of the vicinity: parts in a perfect state, others slightly decomposed.

**RICHMOND CASTLE**, Yorkshire (11th century). The keep, of sandstone, similar to that of Gathersly Moor, generally in good condition; mouldings and carvings in columns of window in a perfect state.

**RIPON**, Yorkshire. An obelisk in the market-place (1781), of coarse sandstone, much decomposed in laminations parallel to the exposed faces.

**RIPON CATHEDRAL.** Lower part, east end, and south-east angle (Norman), of coarse sandstone of the vicinity, in good condition. The west front, the transepts, and tower (of the 12th and 13th centuries), of the coarse sandstone of the vicinity, in fair condition. The mouldings, although generally decomposed, are not effaced. The dog's-teeth ornaments in most parts nearly perfect. The aisles of the naves, the clerestory, and the choir (of the 14th and 15th centuries), of coarse sandstone and magnesian limestone intermixed, not in good condition; the latter stone, on the south side, often in fair condition. The lower parts of the building generally, but particularly the west fronts, which are of coarse sandstone, are very much decomposed.

**RIVAUUX ABBEY**, Yorkshire (12th century). Of a sandstone at Hollands, one mile from the ruins; generally in excellent condition. West front slightly decomposed; south front remarkably perfect, even to the preservation of the original toolmarks.

**SHAFESBURY**, Dorsetshire. St. Peter's Church (15th century). Of a green siliceous sandstone, from quarries half a mile south of the church. The whole building much decomposed. The tower is bound together by iron, and is unsafe, owing to the inferior quality of the stone.

**SPOFFORTH CASTLE**, Yorkshire (14th century). Of coarse red sandstone; more or less, but generally much, decomposed. The dressings of the windows and doors, of a semi-crystalline magnesian limestone, are in perfect state, the mouldings and enrichments being exquisitely sharp and beautiful.

**TINTERN ABBEY** (13th century). Considerable remains of red and grey sandstones of the vicinity, in part laminated. In unequal condition, but for the most part in perfect condition; covered with grey and green lichens.

**TISBURY CHURCH** (13th and 14th centuries; the lower part of the tower of the 12th century). Of calciferous limestone from Tisbury. The dressings are composed of stone throughout, in perfect condition. The ashlar variable; in part much decomposed; the undecomposed portions are covered with lichens. Tombstones in the churchyard generally in good condition, some being more than a century old. The houses of the village built generally of the Tisbury stone, and are in very good condition. The whole covered with lichens.

**WAKEFIELD PARISH CHURCH**, Yorkshire (tower and spire of the 16th century). Of sandstone, much decomposed. The body of the church, of recent date, of sandstone, strongly laminated, and generally decomposed between the laminae.

**WHITBY ABBEY** (13th century). Of stone similar to that of Aislaby Brow, in the vicinity; generally in good condition, with the exception of the west front, which is very much decomposed. The stone used is of two colours, brown and white; the former, in all cases, more decomposed than the latter. The dog's-teeth and other enrichments in the east front are in good condition.

#### LIMESTONE BUILDINGS.

**BATH.** Abbey church (1576), built of an oolite in the vicinity. The tower is in fair condition. The body of the church, in the upper part of the south and west sides, much decomposed. The lower parts, formerly in contact with buildings, are in a more perfect state; the reliefs in the west front of Jacob's ladder are in parts nearly effaced. Queen's Square, north side, and the obelisk in the centre, built above 100 years since, of an oolite with shells, in fair condition. Circus (built about 1750), of an oolite in the vicinity, generally in fair condition, except those portions which have a west and southern aspect, where the most exposed parts are decomposed. Crescent (built above 50 years since), of an oolite of the vicinity, generally in fair condition, except in a few places, where the stone appears to be of inferior quality.

**BRISTOL CATHEDRAL** (of the 13th and 14th centuries). Built of red sandstone and apparently a yellow limestone (magnesian?) strangely intermixed. The red sandstone in all cases decomposed; the limestone more rarely decayed. The tracery, &c. of the windows, which are of the limestone, are in good condition, but the pinnacles and dressings of the same material much decomposed. The east end of the cathedral is a remarkable instance of the decay and preservation of the two stones employed. Norman gateway, west of the cathedral (the upper part of the 15th century), the Norman archway and its enrichments, which are of a very florid character, built of yellow limestone (magnesian?), in excellent condition.

—, **ST. MARY REDCLIFFE** (tower of the 12th century; body of the church of the 15th century). Of oolitic limestone, from Dundry; very much decomposed.

**BURLEIGH HOUSE** (15th century). Of a shelly oolite (Barnack rag), in excellent condition throughout. The late additions are of Ketton stone.

**BYLAND ABBEY**, Yorkshire (12th century). In part of a siliceous grit (principally in the interior), and in part (chiefly on the exterior) of a compact oolite, from the Wass quarries in the vicinity. The west front, which is of the oolite, is in perfect condition,

even in the dog's-teeth and other florid decorations of the doorways, &c. This building is generally covered with lichens.

**COLLEY WESTON CHURCH**, Northamptonshire (14th century). Of a shelly oolite (Barnack rag), in perfect condition throughout.

**DORCHESTER**. **St. Peter's Church** (15th century). Of laminated oolite, somewhat similar to that of Portland, and of a shelly limestone, somewhat resembling that of Hamhill. The latter used in pinnacles, parapets, and dressings. The whole in a decomposed state.

**GLASTONBURY** — **Abbey**. **Joseph of Arimathea's Chapel**. Considerable ruins; Norman, of shelly limestone, similar to that of Doullting; generally in good condition; the zig-zag and other enrichments perfect; the capitals of the columns, corbels, &c. are of blue lias, much decomposed, and in some cases have disappeared. The *Church*. Considerable remains of the choir, and a small portion of the nave (11th century), of shelly limestone, similar to that of Doullting, in good condition. *St. Benedict's Parish Church* (14th century). Of limestone, similar to that of Doullting, in good condition. *St. John the Baptist's Parish Church* (15th century). Of stone similar to that of Doullting, generally in fair condition.

**GLOUCESTER** — **Cathedral**, (Norman for the greater part, altered and cased in the 15th century). Built of a fine-grained and ill-cemented oolite, a shelly oolite, and a red sandstone (north side) intermixed, the former constituting the greatest portion of the edifice. The tower (15th century), of shelly oolite, in perfect condition. The early turrets of the south transept are also in good condition. The body of the building is much decomposed. The great cloister is built of the same materials as the cathedral. The moulded and decorated work is in good condition; the other parts are more or less decomposed. The great cloister is built of a fine oolite, with a compact cement, and is in good condition. *St. Nicholas's Church* (body Norman; tower and spire, 15th century), of a shelly and inferior kind of oolite intermixed, and in unequal condition. *St. Michael's Church* (15th century), built of same stone as that of St. Nicholas, and in the same condition.

**GRANTHAM CHURCH** (13th century). Lofty tower and spire at the west end. Built of an oolite, similar to that of Ancaster, in good condition, more especially the tower, except as to some portions of the base mouldings.

**KETTON CHURCH**, Rutlandshire. (West entrance door, Norman; tower of the 12th or 13th century; nave, aisles, and chancel of the 14th century). Of a shelly oolite (Barnack rag), in good condition. Dog's-teeth, carved corbels, and other enrichments in a perfect state.

**KETTERING CHURCH** (14th and 15th centuries). Of a shelly oolite, fine-grained, the greater portion resembling Barnack rag. The tower and spire in perfect condition. The body of the church in parts slightly decomposed.

**KIRKHAM PRIORY**, Yorkshire (13th century). Inconsiderable remains. The western front and great entrance slightly decomposed throughout; the portions which remain of the body of the church very perfect, but many of the stones are much decomposed. The stone is very similar to that of the Hildeny quarry. The whole is covered with lichens.

**LINCOLN CATHEDRAL** (the minster generally of the 12th and 13th centuries). Of oolitic and calcareous stone of the vicinity; generally in fair condition, more especially the early portions of the west front. The ashler and plain dressings of the south front are, however, much decomposed. The mouldings and carvings of the east front are in a perfect state. *Roman Gate*, of a ferruginous oolite, in fair condition. *The Castle Gateway* (13th century), of an oolitic limestone; ashler much decomposed, dressings perfect.

**MELTON OLD CHURCH**, Yorkshire (12th century). Light semi-compact limestone, similar to that of the Hildeny quarry; generally in good condition, particularly the great west door (of the 11th century), where the zig-zag and other enrichments are perfect. Some stones are much decomposed.

**MONTACUTE**, Somersetshire — **Parish Church** (15th century). Of Hamhill stone, in perfect condition, covered with lichens. The **Abbey** (15th century). Supposed abbot's house and gateway, of Hamhill stone, in good condition. *Montacute House* (17th century), of Hamhill stone, in excellent condition.

**MASTOCK CHURCH**, Somersetshire (15th century). Of a shelly ferruginous brown limestone from Hamhill, in good condition, except the plinth and base mouldings, which are much decomposed. Covered with lichens.

**NEWARK CHURCH** (15th century; the tower, in part, of the 12th century). Of an oolite, similar to that of Ancaster; generally in fair condition, with the exception of parts of the base mouldings. The building is covered with a grey lichen. *The Castle* (Norman, with additions in the 15th century). Chiefly of sandstone of the vicinity; in unequal condition. A large portion of the dressings of the windows, &c. are of oolite,

probably from Ancaster. *Town Hall* (50 or 60 years old). Built of the Ancaster oolite; in good condition; in some blocks, however, there is an appearance of lamination, where decomposition has to a slight extent taken place.

**OXFORD CATHEDRAL**, Norman (12th century). Chiefly of a shelly oolite, similar to that of Taynton; Norman work in good condition, the latter work much decomposed. *Merton College Chapel* (13th century). Of a shelly oolite, resembling Taynton stone; in good condition generally. *New College Cloisters* (14th century). Of a shelly oolite (Taynton), in good condition. The whole of the colleges, churches, and other public buildings of Oxford, erected within the last three centuries, are of oolitic limestone from Heddington, about one mile and a half from the university, and are all, more or less, in a deplorable state of decomposition. The plinth, string-courses, and such portions of the buildings as are much exposed to the action of the atmosphere, are mostly of a shelly oolite from Taynton, fifteen miles from the university, and are universally in good condition.

**PAUL'S ST., CATHEDRAL, LONDON** (finished about 1700). Built of Portland oolite, from the Grove quarries on the east cliff. The building generally in good condition, especially the north and east fronts. The carvings of flowers, fruit, and other ornaments are throughout nearly as perfect as when first executed, although much blackened; on the south and west fronts, larger portions of the stone may be observed of their natural colour than on the north and east fronts, occasioned by a very slight decomposition of the surface. The stone in the drum of the dome, and in the cupola above it, appears not to have been so well selected as the rest; nevertheless scarcely any appreciable decay has taken place in those parts.

**PICKERING CHURCH**, Yorkshire (13th and 14th centuries). Oolite rock of the neighbourhood; very much decomposed; the windows, mullions, and buttress angles obliterated.

**PICKERING CASTLE** (14th century). The walls of the oolite of the neighbourhood, and the quoins of a siliceous grit. The whole in fair condition.

**PORTLAND, Dorsetshire**—*New Church* (built 1766), of Portland oolite, fine roach; in a perfect state, still exhibiting the original tool marks. *Wakeham Village, Tudor House*, of Portland oolite, in excellent condition. *Old Church*, in ruins, near Bow and Arrow Castle (15th century), of Portland oolite, resembling top bed; in very good condition; original chisel marks still appear on the north front. *Bow and Arrow Castle*. Considerable remains of the keep, many centuries old, of Portland oolite; the ashlar resembles the top bed, and is in perfect condition; the quoins and corbels of the machicolated parapet appear to be of the cap bed of Portland oolite, and are in good condition.

**SALISBURY CATHEDRAL** (13th century). Of siliceiferous limestone from Chillmark quarry. The entire building is in excellent condition, except the west front, which in parts is slightly decomposed. The building generally covered with lichens.

**SANDSFOOT CASTLE**, near Weymouth (temp. Hen. VIII.). Considerable remains of keep, chiefly of Portland oolite, partly of the top bed and partly of the fine roach; generally in excellent condition, with the exception of a few and apparently inferior stones. The inside ashlar of the walls is of large-grained oolite, apparently from the immediate vicinity of the castle, much decomposed.

**SOMERTON CHURCH**, Somersetshire (14th century). Built chiefly of blue lias; the quoins, buttresses, parapets, and other dressings of a coarse ferruginous shelly limestone, in various stages of decay. The parapet of the clerestory of a lighter-coloured stone, in good condition.

**STAMFORD**—*St. Mary's Church* (13th century). Of a shelly oolite (Barnack rag), in fair condition. *St. John's Church* (14th century). Of similar stone, ill selected, and consequently decomposed in parts and in laminations, according to the direction of the beds of shells. *St. Martin's Church* (14th century). Of similar stone, in good condition. *All Saints* (lower part of the body of the church 13th century; the remainder 15th century). Tower and spire in fine condition; body of the church decomposed. *Standwell's Hotel*, built twenty-four years since of an oolite similar to that of Ketton; in perfect condition. *St. Michael's New Church*. Built four years since; no appearance of decomposition.

**WELLS, THE CATHEDRAL**. West front (13th century), upper part of tower (14th century), of shelly limestone, similar to that of Douling, generally decomposed, but not to any great extent. North flank (porch and transept 13th century, the remainder of the 14th century), of similar stone, in good condition, except lower part of flank and west tower. The central tower (of the 14th century) in very good condition. South side of the cathedral generally in good condition. *Chapter House* (13th century, with additions of the 15th century). The whole in good condition excepting the west front of the gateway, which is decomposed. Close gates (15th century) much de-

composed, but especially on the south and south-west. The cloisters (15th century) generally decomposed, particularly the mullions and tracery.

**WESTMINSTER ABBEY** (13th century). Built of several varieties of stone, similar to that of Gatton or Ryegate, which is much decomposed, and also of Caen stone, which is generally in bad condition; a considerable portion of the exterior, especially on the north side, has been restored at various periods, nevertheless abundant symptoms of decay are apparent. The cloisters, built of several kinds of stone, are in a very mouldering condition, except where they have been recently restored with Bath and Portland stones. The west towers, erected in the beginning of the 18th century with a shelly variety of Portland oolite, exhibit scarcely any appearance of decay. Henry the Seventh's Chapel, restored about twenty years since with Combe Down Bathstone, is already in a state of decomposition.

**WINDRUSH CHURCH** (15th century). Of an oolite from the immediate vicinity; in excellent condition. A Norman door on the north side, enriched with the bird's-beak and other characteristic ornaments, is in perfect condition. Tombstones in the churchyard, very highly enriched and bearing the dates of 1681, 1690, apparently of Windrush stone, are in perfect condition.

**WYKE CHURCH**, Dorsetshire (15th century). Of oolite, similar to Portland, the whole in good condition, except the mullions, tracery, and dressings of doors and windows, which are constructed of a soft material, and are all decomposed. On the south side, the ashler is in part covered with rough-cast. The entire building is thickly covered with lichens.

#### MAGNESIAN LIMESTONE BUILDINGS.

**BEVERLEY**, Yorkshire. The minster (12th, 13th, and 14th centuries), of magnesian limestone from Bramham Moor, and an oolite from Newbold; the former, which is used in the west tower, central tower, and more ancient parts of the minster, generally in good condition; but in other parts of the building the same material is decomposed. The Newbold stone, chiefly employed on the east side, is altogether in a bad condition. Some of the pinnacles are of Oulton sandstone, and are in bad condition. The building is partly covered with lichens. *St. Mary's Church* (14th century), now in course of restoration, of magnesian limestone and oolite, supposed to be from Bramham Moor and Newbold, respectively. The ancient parts are in a very crumbling state, even to the obliteration of many of the mouldings and enrichments.

**BOLSOVER CASTLE**, Derbyshire (1629). Mostly in ruins; of magnesian limestone of several varieties, and of a calcareous fine-grained sandstone. The dressings, which are generally of sandstone, are much decomposed, in some instances to the entire obliteration of the mouldings and other decorations, and to the destruction of the form of the columns, rustications, &c. Most of the string courses, a portion of the window dressings, and the ashler, which are of magnesian limestone, are generally in excellent condition.

**BOLSOVER CHURCH**, Derbyshire (15th century). Of a magnesian-calcareous sandstone, more or less in a decomposed state throughout.

**CHEPSTOW CASTLE**, Monmouthshire (11th and 12th centuries, with additions of the 14th century). Of mountain limestone and old red sandstone; the former in good condition, the latter decomposed. Dressings of door, window, archway, and quoins are for the most part of magnesian limestone, and in perfect condition. The remainder is of red sandstone, and is generally much decomposed. Chapel (of the 12th century), mouldings and carvings of windows, &c., which are of magnesian limestone, in perfect condition.

**DONCASTER (OLD) CHURCH** (15th century). Of an inferior magnesian limestone, generally much decomposed, more especially in the tower, and on the south and west sides; now under general and extensive repair.

**HEMINGBOROUGH CHURCH**, Yorkshire (15th century). Of a white crystalline magnesian limestone. The entire building is in a perfect state, even the spire, where no traces of decay are apparent.

**HOWDEN CHURCH**, Yorkshire (15th century). Partly of magnesian limestone of a deep yellow colour, and partly of a coarse siliceous grit of a ferruginous colour. Dressings and enrichments, and the central tower, are of the former stone, generally decomposed, particularly at the top of the tower. The other parts of the edifice, built of the grit, are very much decomposed.

**HUDDESTONE HALL**, Yorkshire (15th century). Of semi-crystalline magnesian limestone from the neighbouring quarry. In excellent condition, even to the entire preservation of the mouldings of the chapel window in the south-west front. The outer gate piers in the fence wall, also of magnesian limestone, very much decomposed.

**KNARESBOROUGH CASTLE**, Yorkshire (12th century). Magnesian limestone, carious in part;

generally in very good condition, except on the south and south-west portions of the circular turrets, where the surface is much decomposed. The mouldings generally are in a perfect state. The joints of the masonry, which is executed with the greatest care, are remarkably close. The stone of the keep, which is of a deep brown colour, and much resembles sandstone, is in good condition, especially on the south-west side.

**KONINGSBOROUGH CASTLE**, Yorkshire (Norman). Coarse-grained and semi-crystalline magnesian limestone, from the hill eastward of the castle; in perfect condition. The masonry is executed with great care, the joints very close, but the mortar within them has disappeared.

**RIPON CATHEDRAL**. Lower part, east end, south-east angle (Norman), of coarse sandstone from the vicinity, in good condition. The west front, the transepts, and tower (of the 12th and 13th centuries), of coarse sandstone of the vicinity, in fair condition. The mouldings, although generally decomposed, are not effaced. The dog's-teeth ornament in most parts nearly perfect. The aisles of the nave, the clerestory, and the choir (of the 14th and 15th centuries), of coarse sandstone and magnesian limestone intermixed, not in good condition. The latter stone, on the south side, often in fair condition. The lower parts of the building generally, particularly the west fronts, which are of coarse sandstone, are much decomposed. An obelisk, in the market-place (1781), of coarse sandstone, is much decomposed, and in laminations parallel to the exposed faces.

**ROBIN HOOD'S WELL**, Yorkshire (1740). A rusticated building, of magnesian limestone, in perfect condition.

**ROCHE ABBEY**, Yorkshire (12th century). Inconsiderable remains, of semi-crystalline magnesian limestone from the neighbouring quarry, generally in fair condition. The mouldings and decorated portions are perfect. Gate-house (12th century) generally decomposed, with the exception of the dressings and mouldings, which are perfect.

**SELBY CHURCH**, Yorkshire (nave and lower part of the tower of the 11th century; the west front and aisles of the 12th century; and the choir with its aisles of the 14th century). The Norman portion of the building, which is of grey magnesian limestone, is in excellent condition, particularly the lower part. The early English portions of the building are also of magnesian limestone, and in a partially decomposed state. The later portions of the building, which also are of magnesian limestone, are much decomposed and blackened.

**SOUTHWELL CHURCH**, Notts (of the 10th century). Of magnesian limestone, similar to that of Bolsover Moor, in perfect condition. The mouldings and enrichments of the doorway appear as perfect as if just completed. The choir, which is of the 12th century, and built of a stone similar to that of Mansfield, is generally in good condition.

**SPOFFORTH CASTLE**, Yorkshire (14th century). Of coarse red sandstone, generally much decomposed. The dressings of the windows and doors, of a semi-crystalline magnesian limestone, are in a perfect state, the mouldings and enrichments being eminently sharp and beautiful.

**STUDLEY PARK**, Yorkshire. Banqueting house, about 100 years old, of yellowish magnesian limestone, in perfect condition.

**THORPE ABBEY VILLAGE**. The houses generally of this village are built of magnesian limestone from the vicinity; they are in excellent condition, and of a very pleasing colour.

**THORPE SALVIN**, near Worksop. Manor-house (15th century), in ruins. Of a siliciferous magnesian limestone and a sandstone, in unequal condition; the quoins and dressings are generally in a perfect state. *Parish Church* (15th century), also of a siliciferous variety of magnesian limestone and a sandstone, in unequal but generally fair condition. A Norman doorway under the porch is well preserved.

**TICKHILL CHURCH**, Yorkshire, (15th century). Of magnesian limestone, in excellent condition. The lower part of the tower (of the 12th century) also in fair condition.

**YORK. Ancient Buildings**: **CATHEDRAL** (transepts, 13th century; tower, nave, &c., 14th century). Of magnesian limestone, from Jackdaw Craig. West end and towers restored thirty years since; they are generally in fair condition, but some of the enriched gables and other decorations are obliterated. The transepts are in many places much decomposed, especially in the mouldings and enrichments. The central tower is generally in good condition, but several of the enriched parts are decomposed. *St. Mary's Abbey* (12th century), of magnesian limestone. West front of the church generally much decomposed; the north flank in better condition, but in parts much decomposed. The gateway, which is of Norman origin, is in fair condition. *Roman Multangular Tower*. Built of small stones; such as are of magnesian limestone are in good condition. *St. Denis's Church*. Norman doorway, of magnesian

limestone; south side highly enriched with zig-zag and other ornaments; the columns are gone; the parts which remain are in good condition. *St. Margaret's Church* (15th century), of magnesian limestone; east front much exposed, and in good condition. The porch is of Norman date, and has been reconstructed; four bands of enrichment in the head, in tolerably fair condition, but many stones, particularly those of a deep yellow brown colour, are much decomposed. *The other churches of York* (which are of the 14th and 15th centuries) are built of magnesian limestone, and are generally in an extremely decomposed state; in many instances all architectural detail is obliterated. *Modern Buildings*: THE MUSEUM, of Hackness sandstone, built nine years since, much decomposed wherever it is subject to the alternation of wet and dry, as at the bottom of the columns of the portico, plinth, &c. THE CASTLE (recently erected); the plinth of the boundary wall (which is of Bramleyfall sandstone) already exhibits traces of decomposition. *York Savings Bank*. Huddersfield stone (?), in good condition.

WORKSOP CHURCH (principally of the 13th century), of a siliciferous variety of magnesian limestone and of a sandstone; in very unequal condition. Some parts are very much decomposed, whilst others are in a perfect state.

1666. Valuable as the above Report is, there remain points, perhaps minor ones, which are still desiderata for the architect; but we are, nevertheless, much indebted to all concerned in its production. It contains a sufficiently ample account of the principal quarries of the country to guide the architect in the choice of the material, and is almost the only thing that the government of this country has ever done to advance architecture as a science: for it, as an art, it does not appear probable much will be done till things are very much changed. We shall close our account of the stone of England with a very useful table of the chemical analysis of sixteen specimens of stone, which were examined by Messrs. Daniel and Wheatstone, whose names are sufficient to impart a value to it in the mind of every scientific person.

1667. The above table gives the results of the chemical analysis of sixteen specimens of stone, arranged according to their respective classes. The names of the quarries are inserted under the general divisions of the different species of stone, and the specimens were considered as fair average samples of the workable stone in such quarries. The experiments were conducted by Messrs. Daniel and Wheatstone. In subsection 1500. we have already supplied a table, to which the reader is referred for the crushing weights of the stones therein mentioned; and that, added to the information which the immediately preceding pages supply, will, we trust, be all that is necessary on this branch of the subject under consideration.

## SECT. II.

## GRANITE.

1668. Among the primitive rocks of the globe, whose period of creation is considered by geologists as antecedent to that of organic beings, is that of granite, whose use in architecture seems to bid defiance to time itself. The term granite appears to be a corruption of the Latin word *gerânites*, used by Pliny to denote a particular species of stone. Tournefort, the naturalist, in the *Account of his Voyage to the Levant* in 1699, is the first of modern writers who uses the name. The word seems to have been applied by antiquaries to every granular stone susceptible of use in architecture or sculpture, in which vague sense it was used by mineralogists, until about fifty years since, when true granite was classed as a particular mountain rock. Its constituent parts are concretions of felspar, quartz, and mica, intimately joined together, but without any basis or ground. These parts are variable in quantity, so that sometimes one, sometimes the other, and frequently two of them, predominate over the third. The felspar, however, generally predominates, as mica is the least considerable ingredient of the rock. In some varieties the quartz is wanting, in others the mica; but where these peculiarities occur, the granites must be considered as varieties, not as distinct species.

1669. The constituent parts differ in their magnitude, alternating from large to small and very fine granular. The colour, moreover, is very variable, depending principally on the predominating ingredient, — the felspar, the quartz, and the mica having usually a grey colour. The felspar is mostly white, inclining to grey and yellow, sometimes red, and even also milk white, sometimes flesh-red; rarely grey, yellow, or green. The quartz is usually grey, seldom milk-white, and always translucent. The mica is usually grey, and sometimes nearly black. The felspar in granite has usually a vitreous lustre, and of perfectly foliated fracture; yet in some varieties it passes into earthy, with the loss of its hardness and lustre; in other words, it has passed into porcelain earth. The appearance in question is sometimes produced by the weathering of the felspar, and sometimes it appears to be in its original state. When pyrites are found in the veins which traverse granite, the vicinuous felspar and mica are converted into a species of steatitical matter by the action of the sulphuric acid formed during the decomposition of the pyrites. The mica also is liable to decomposition from exposure to the atmosphere, but the quartz never alters. In Cornwall, there is a considerable portion of the granite in which earthy felspar is found.

1670. Granite is not decomposed by acids, and is only imperfectly and slowly calcinable in a great heat. Those species which contain much white felspar, and only a small portion of quartz, like the greater part of the granites of Cornwall and Devonshire, are liable to decomposition much sooner than many of the Scotch granites, in which the quartz is more abundant, and equally disseminated. In the selection of the Cornish and Devon granites, those are to be preferred which are raised in the largest blocks and are easiest worked, which, for common purposes, answer well enough, such as for paving-stones and the like; but harder granite must be sought for than Devonshire or Cornwall produces, where the construction is of importance; for the masses in these counties are mostly in a condition of rapid disintegration and decay, which seems chiefly attributable to their containing a large portion of potass. The Naval Hospital of Plymouth is built of a granite whose parts appear to have been well selected. It was erected upwards of seventy years since, and, except in the columns of the colonnades, does not exhibit symptoms of decay. In these, on their more exposed sides, the disintegration of the felspar has commenced, and lichens have already attached their roots to some parts of the surfaces.

1671. The grey granite, or moorstone as it is called in Cornwall, is got out in blocks by splitting it with a number of wedges applied to notches *pooled* in the surface of the stone about four inches apart. The *pool holes* are sunk with the point of a *pick*, much in the same way as other hard quarry stones are split. The harder the moorstone the nearer it can be split to the scantling required. All granite may be wrought, and, indeed, is wrought into mouldings by means of pointed tools of various weights and sizes; but it is first roughed out by means of heavy hammers, whose shape is formed by two acute angled triangles, joined base to base by a rectangle between them, thus . Red granite, sometimes yellowish, and generally interspersed with black mica, is found in Devonshire, and indeed at Mount Edgecumbe there are fine tables of it equal to the finest oriental granite, and it is found also in other parts of England; but for hardness, and in works where durability is indispensable, the granite from Aberdeen and Dundee is to be preferred by the architect. These take an admirable polish, and are superior to all others which the island produces. Of these the red generally is harder than the grey sorts, but more difficult to work. The Peterhead, from the vicinity of Aberdeen, is perhaps the best, and it is, moreover, in appearance, the most beautiful which Scotland affords; indeed, in point of beauty, it is only surpassed by the oriental granites.

1672. The common granite is the material chiefly used for paving the roads of the metropolis.

A cubic foot of Aberdeen grey granite weighs  $166\frac{1}{2}$  lbs.

### SECT. III.

#### MARBLE.

1673. With the architect and sculptor the name of marble is applied to all stones, harder than gypsum, which are found in large masses, and are susceptible of a good polish. On this principle, under the head of marble, are included many varieties of limestone, porphyry, and even granite and fine-grained basalts. But with mineralogists the word is used in a much more restricted sense, and is confined to such varieties of dolomite, swinestone, and compact and granularly foliated limestone as are capable of receiving a good polish.

1674. The *external characters* are as follows: colours white, grey, red, yellow, and green. Has generally but one colour, though it is often spotted, dotted, striped, and veined. Occurs massive, and in angulo-granular distinct concretions. Internally it alternates from shining to glistening and glimmering; lustre intermediate between pearly and vitreous. Fracture foliated, but oftentimes inclining to splintery. Fragments indeterminate, angular, and rather blunt-edged. More or less translucent. Brittle, and easily frangible. Its *chemical characters* are, that it generally phosphoresces when pounded, or when thrown on glowing coals. It is infusible before the blow-pipe. Dissolves with effervescence in acids.

Constituent parts, Lime	-	-	-	56.50
Carbonic acid	-	-	-	43.00
Water	-	-	-	0.50

100.00

1675. All the varieties may be burnt into quicklime; but it is found that in many of them the concretions exfoliate and separate during the volatilization of their carbonic acid, so that by the time that they become perfectly caustic, their cohesion is destroyed, and they fall into a kind of sand, a circumstance which renders it improper to use such varieties in a common kiln. The most important use, however, of marble is as a material for decoration.

1676. The varieties of marble are almost infinite, and their classification would be perhaps useless here. Among those in use with the ancients, the white marble of mount Penteles in Attica, thence called *Pentelican*, seems to have held the first rank. It was used in the Parthenon and other buildings in Athens, and was also in high repute with the Greek sculptors. The *Parian* marble of the finest description was obtained from Mount Marpessus in the island of Paros, whence it was also called *Marpessian* marble. This sort was also highly esteemed. The Parian marble was sometimes termed *Lychnæus*, from its employment for candelabra, and *Lygdinum*, from the promontory of Lygdos. Another marble of antiquity was that from Mount Hymettus in Attica. Thasus and Lesbos produced white marbles, much esteemed; and the latter also a marble of a black colour. But a marble whiter than even that of Paros was found at Luna in Etruria. Amongst the white marbles also was the *Marmor Phellense* from Mount Phelleus; *Coraliticum*, from the neighbourhood of the river Coralios in Phrygia, termed also *Sangarium*, from a different name of the same river; and the *Cyzicum*, from the quarries of Cyzicus in Asia Minor. The *Chernites* resembled ivory in its colour. Among the black marbles were the *Synnadicum*, or *Phrygium*, from the vicinity of the city of Synnada in Phrygia; that of *Tenarus*, the *Marmor Libicum*, or *Numidian*, also called *Luculleum*, called by the French *noir antique* or *rouge antique*. Of a transparent black colour also was the celebrated *Chium Marmor*, from Mount Pelineus in the island of Chios. The *Marmor Obsidianum*, from Ethiopia, was also black. Of the same colour, but veined, was that from the isle of Proconesus, called *Proconesian* or *Cyzican* marble. Mount Taygetes produced the *Marmor Laconicum*, of a green colour, more generally now known by the name of *verd antique*. That of *Carystus* was of a mingled green. The *Atraicum Marmor*, from Mount Atrax in Thessaly, was a mixture of white, green, blue, and black. The *Tiberian* and *Augustan* marbles were from Egypt, and of a green colour. That of a dark green, which is called *serpentino antico*, from the alleged resemblance of its colour to the skin of a serpent, was anciently called *Marmor Apites* or *Memphites*, and was obtained, as its second name imports, from the neighbourhood of Memphis. The *Corinthian* was a yellow marble; the *Phengites*, from Cappadocia,

white with yellow spots. The *Rhodian* was marked with spots of a golden appearance; and that of *Melos*, obtained from Mount *Acyntus*, was also yellow.

1677. The *Parian* marble, above mentioned, consists almost entirely of carbonate of lime; that of *Carrara*, in Italy, is often mixed with granular quartz in considerable proportion. Dr. Clarke says that while the works in *Parian* marble remain perfect, those in *Pentelic* marble have become decomposed, and sometimes exhibit a surface as earthy and rude as that of common limestone. This is considered to be principally owing to veins of extraneous substances which intersect the *Pentelic* quarries, and which appear more or less in all the works executed in this kind of stone. The *Parian* marble has a waxy appearance when polished; it hardens by exposure to the air, and must be held in estimation even now, as the material from which were formed the *Venus di Medici*, the *Diana Venatrix*, the colossal *Minerva Pallas* of *Velletri*, and the *Capitoline Juno*. The marbles known by the names of *Verde antico* and *Verde di Corsica* are composed of limestone, calcareous spar, serpentine, and asbestos.

1678. The marbles of France are many of them extremely beautiful, but their use is chiefly confined to that country.

1679. The marbles of the British Islands deserve more notice from the English architect than they have hitherto received. In England there are but few as yet quarried of granular foliated limestone, the greater number of varieties of them belonging to the *flötz* or secondary limestone. *Derbyshire* and *Devonshire* abound with marble; but the most remarkable, and perhaps most beautiful, of the English marbles, is that of *Anglesea*, called *Mona marble*, and much resembling *Verd antique*. Its colours are greenish black, leek green, and sometimes purple, irregularly blended with white, but they are not always seen together in the same piece. The white part is limestone, the green shades are said to be owing to serpentine and asbestos. The black marbles found in England are varieties of *lucullite*.

1680. Of the Scotch marbles the principal are the *Tiree*, of which there are two varieties, red and white. The *Iona*, whose colours are a greyish white and snow white, sometimes intermixed with *steatite*, which gives it a green or yellow colour in spots known under the name of *Iona* or *Icolmkill* pebbles. It does not take a high polish. The *Skye* marble, of greyish hue, with occasionally various veins. The *Assynt* varieties of white, of grey, and dove colour. *Glen Tilt* marble, white and grey, with occasionally yellow and green spots. Marble of *Balliculish*, of a grey or white colour, and capable of being produced in considerable blocks. *Boyne* marble, grey or white, and taking a good polish. *Blairgowrie*, in *Perthshire*, of a pure white colour, fit, it is said, to be employed in statuary and for architectural purposes; and *Glenavon*, a white marble, said by *Williams* (*Natural History of the Mineral Kingdom*) to be a valuable marble, is not used, from the remoteness of its situation and the difficulty of access to it.

1681. The black marbles of Ireland, which have of late been much introduced for architectural purposes, are *lucullites*. In the county of *Waterford* are several kinds. At *Toreen* is a fine variegated sort of various colours, viz., chesnut brown, white, yellow, and blue, and taking a good polish. A grey marble, beautifully clouded with white, and susceptible of a good polish, has been found near *Kilerump*, in the parish of *Whitechurch*. In the same county. At *Loughlougher*, in the county of *Tipperary*, a fine purple marble is found, which is said to be beautiful when polished. Several variegated marbles are described by *Smith* in the county of *Cork*, but it does not appear certain whether these and others are granular limestone. The county of *Kerry* affords several variegated marbles, such as that found near *Tralee*. Marble of various colours is found in the same county, in the islands near *Dunkerron*, in the river of *Kenmare*: some are purple and white, intermixed with yellow spots; and some beautiful specimens have been seen of a purple colour, veined with dark green.

1682. The principal part of the supply to England of foreign marble is from *Carrara*, a small Italian town in the duchy of *Massa*. The quarries at this place were celebrated from an early period, and spots are still shown about them whence they dug the marble for the *Pantheon*. Masses of marble are sometimes procured here nine feet in length and from four to six in breadth. The marble produced besides the white statuary is of different colours and veins. The quarries are the property of the principal inhabitants of the town, who carry on an extensive trade in the article; but the difficulty of choosing the marble has induced artists to settle there for the execution of their works, and the consequence is, that sculpture abounds and flourishes in the town.

1683. There is a beautiful species of yellow marble obtained from the quarries near *Siena*, but the quantity imported is not very great.

## SECT. IV.

## TIMBER.

1684. The information we propose here to lay before the reader relative to the different species of timber is extracted from Miller's *Gardener's Dictionary*, Rondelet's *Art de Bâtir*, Rees's *Cyclopædia*, and Hunter's edition of Evelyn's *Sylva*. To give any thing like the information that would satisfy the botanist would be out of place in an architectural work ; and we therefore confine our observations to those which will be useful to the student.

1685. OAK. Of this most valuable timber for building purposes Vitruvius (lib. ii. cap. ix.) enumerates five species, which it would now be difficult to identify. That some species of the *Quercus* of the botanists are more valuable for building purposes than others no doubts exist. Evelyn seems to commend especially the Irish oak, because of its withstanding the efforts of the worm ; but it is not easy to ascertain the particular species to which he alludes. In the present day the Sussex oak is esteemed the most valuable ; a value, according to some authors, derived from the nature of the soil and from good management in the culture, which is an object of no small importance.

1686. Generally, it has been usual to consider England as producing, without difference in quality, but one species of oak ; but two sorts are well known to the English botanist, the *Quercus Robur* and the *Quercus jessiflora*. The former is found throughout the temperate parts of Europe, and is that most common in the southern parts of England. Its leaves are formed with irregular sinuosities, and their footstalks are short, occasionally almost without any at all. It attains a very large size, and the wood is tolerably straight-grained and pretty free from knots, in many instances resembling the German species called wainscot. It is easily split for making laths for plasterers and slaters, and is beyond doubt the best sort for joists, rafters, and other purposes where stiff and straight-grained timber is a desideratum. In the *Quercus jessiflora*, which, though found about Dulwich and Norwood, according to Miller, appears to be the common oak of Durham, and perhaps of the north of England, the leaves have long footstalks, frequently an inch in length, and their sinuosities are not so deep, but are more regular than those of the *Robur* just described. The acorns are so close to the branches as to have scarcely any stalks. The wood is of a darker hue, and the grain is so smooth that it resembles chesnut. Than the *Robur* it possesses more elasticity, hardness, and weight, but in seasoning it is subject to warp and split ; hence unfit for laths, which in the north of England are rarely of oak. There is no reason for supposing, as has been conjectured, that the oak of the Gothic roofs of the country is of this species, though we are aware of the great durability of the oak in the buildings in the northern part of the island.

1687. The specific gravity of the species first named, that is, the *Quercus Robur*, may be taken at about '800, and the weight of a cube foot 50·45 lbs. That of the last-named at '875, and the weight of a cube foot at about 55·00 lbs. Their cohesive force and toughness are proportionable.

1688. The American species scarcely claim a notice here, because their use in England is, from every circumstance, out of the question. Of the red oak of Canada (*Quercus rubra*), the only one of which the use could be contemplated, we merely observe, that it is a light, spongy, and far from durable wood, though, in the country, in many instances useful. Its growth is rapid, and it rises to the height of 90 or 100 feet.

1689. There is a species of oak imported from Norway, which has received the name of *clapboard*, and another imported from Holland, known under the name of *Dutch wainscot*, though grown in Germany, whence it is floated down the Rhine for exportation. The latter is destitute of the white streaks which cross the former, and is thereby distinguished from it. The use of these woods has latterly much diminished in England. They are both softer than common oak, and the clapboard far inferior to wainscot. They are more commonly used for fittings and fixtures, whereto they are well adapted. In damp situations, oak decays gradually from its external surface to the centre of the tree ; the ring on the outside, which it acquired in the last year of the growth of the tree, decaying first ; but if the tree be not felled till past its prime, its decay is reversed by its commencement at the centre. An oak rarely reaches its prime under the age of an hundred years ; after that period, which is that of its greatest strength, it cannot be considered as fit for building purposes ; and, indeed, it may be taken as a rule, that oak before arriving at its maturity is stronger than that which has passed it.

1690. If the architect has the opportunity of selecting the timber whilst in a state of growth, he will, of course, choose healthy, vigorous, and flourishing trees. Those in which the trunks are most even are to be preferred. A mark of decay is detected in any swelling above the general surface of the wood. Dead branches, especially at the top of the tree, render it suspicious, though the root is the best index to its soundness. The notion of Alberti (*De Re Edificatoria*), of using all the timber in the same building from

the same forest, is a little too fanciful for these days, though we confess we have some misgivings in impugning an authority which, in most other respects, we are inclined to receive with the highest veneration.

1691. In felling not only the oak, but all other large trees, the great branches should be first cut off, so that the tree may not be injured or strained in its fall; and the trunk, moreover, must be sawed as close to the ground as possible. When felled, but not before, it is to be barked, trimmed of its branches, and left to season. Before, however, leaving it for this purpose, it is considered by workmen better to square it, which, it is thought, prevents its tendency to split. If to be employed for posts or bearing pieces, boring it has been employed with success; but it is needless to observe, that in pieces subject to transverse strains such a practice is not to be spoken of.

1692. The pieces selected for building must be chosen with the straightest grain; but there are pieces which are occasionally employed, as for knees and braces, wherein a curvilinear direction of the fibres of the timber is extremely desirable. It may, however, be generally stated, that, in the case of two equal-sized and seasoned pieces, the heavier is the piece to be preferred.

1693. In oak, as in all other woods, the boughs and branches are never so good as the body of the tree; the great are stronger than the small limbs, and the wood of the heart stronger than all. When green, wood is not so strong as when thoroughly dry, which it rarely is till two or three years after it is felled. It is scarcely necessary to say, that, containing much sap, it is not only weaker, but decays sooner. It is weakened by knots, at which, in practice, it is found that fractures most frequently occur; and it is important to the architect to recollect that he should always reject cross-grained pieces.

1694. The great use of oak in this country is more for ship-building purposes than for architectural, its use, except in the provinces, being principally confined to pieces which are much liable to compression, or where great stiffness is required, or in pieces like sills to windows and door-cases, where there is much alternation of dryness and damp. So early as 1788, the consumption of oak for ship-building purposes was, in that year, upwards of 50,000 loads.

1695. When of good quality, it is more durable than any other wood which is procurable of a like size. In a dry state, it is ascertained to have lasted nearly a thousand years. The open-fibred porous oak of Lincolnshire, and some other places, is a bad sort. The best is that with the closest grain and the smallest pores. The colour, as is well known, is a fine brown; that which partakes of a reddish hue is not so good as the other. The smell of it is peculiar; it contains gallic acid, and it assumes a black purple colour when damp, by contact with iron. It warps and twists much in seasoning, and shrinks in width about one thirty-seventh part.

1696. CHESNUT. One of the finest of the European timber trees, the *Fagus castanea* of botanists, was heretofore so common in this country, that Fitzstephen, in his description of London about the time of Henry II., mentions a fine forest of chesnuts as growing on the northern side of the city. We know that it was much used in the buildings of our ancestors, and was, perhaps, even the chief timber employed. The young tree vies with the oak in durability, from the small proportion of sapwood it contains. Of its durability, the roofs of Westminster Hall, that of King's College, Cambridge, and that of Notre Dame, at Paris, are cited as examples, though the fact of the latter being of chesnut is doubted by Rondelet, who says that Buffon and D'Aubenton thought it a species of oak, which may be the case in the roof first named.

1697. Chesnut, however, is not to be trusted as is oak. As Evelyn observed, it is often well-looking outside, when decayed and rotten within. Belidor says it soon rots when the ends of timbers of it are closed round in a wall.

1698. It is, perhaps, from the circumstance of its colour so nearly resembling that of oak, that one timber has so often been mistaken for the other. The difference, however, is, that the pores of the sapwood of the oak are larger and more thickly set and easily distinguished, whilst those in the chesnut require magnifying powers to be distinguished. But a more decided difference is, that the chesnut has no large transverse septa. It is far easier to work than oak, and is not very susceptible of swelling and shrinkage. From what has been mentioned above, it may be inferred that the wood, though tough and compact, is, when young, hardest and most flexible, the old wood being often shaky and brittle.

1699. Water pipes of this tree endure much longer than those of elm; and for tubs and vessels to hold water, it is superior to oak; for when once thoroughly seasoned, it will neither shrink nor swell, on which account it is used by the Italians for wine tuns and casks. It will thrive on most soils, but rather delights in a rich loamy land, succeeding well, also, on that which is gravelly, clayey, or sandy. Mixed soils are suitable to it, and it is found in the warmer mountainous situations of most parts of Europe.

1700. From the experiments, the cohesive force of a square inch of chesnut, when dry, varies from 9570 to 12000 lbs., and the weight of a cubic foot, when dry, is from 43 to 55 lbs.

1701. **BEECH** (*Fagus Sylvatica*). A beautiful tree, growing to a considerable height, and carrying a proportionable trunk. It flourishes most in a dry warm soil, and grows moderately quick. The wood is hard, close, has a dry even grain, and, like the elm, bears the drift of spikes. The sorts of beech are the brown or black, and the white beech. It is common throughout Europe. In the southern parts of Buckinghamshire, where the soil is chalky, it is particularly abundant; and such is the case near Wablerton, in Sussex, on the southern range of chalk hills, where the beeches are very fine.

1702. Constantly immersed in water, the beech is very durable; such also is the case with it when constantly dry; but mere damp is injurious to it, and it is very liable to injury by worms, though to these Duhamel considers it much less liable when water-seasoned, than when seasoned in the common way. To render it less liable to the worm, it has been recommended to fell it about a fortnight after Midsummer, to cut it immediately into planks, which are to be placed in water about ten days and then dried. Beech is little used in building, except for piles, in which situation, if constantly wet, they are very durable. From its uniform texture and hardness, it is a good material for tools and furniture, and of it, in boards and planks, large quantities are brought to London. It is without sensible taste and smell, easy to work, and susceptible of a very smooth surface. The white sort is the hardest, though the black is tougher, and, according to Evelyn, more durable. The weight of a cubic foot varies from 43 to 53 pounds.

1703. **WALNUT** (*Juglans, quasi Jovis glans*) is of several sorts. The *Juglans Regia*, or common walnut, was formerly much cultivated in this island, as well for the sake of its timber as of its fruit. On the former account the importation of mahogany has long since rendered its cultivation less common. It flourishes better in a thin limestone soil, than in one that is rich and deep, and, if raised for timber, should not be transplanted, but remain in the place where it is sown. For furniture, from its rich brown colour, it is by many persons preferred to mahogany. Its scarcity renders its employment rare for building purposes, though by the ancients it was so employed. One of its properties is, that it is less liable to be affected by worms than any other timber, cedar only excepted; but from its brittle and cross-grained texture, it is not generally useful for the main timbers of a building.

1704. The heart-wood is of a greyish brown with dark brown pores, often veined with darker shades of the same colour, which are much heightened by oiling. The texture is not so uniform as that of mahogany, nor does it work so easily, but it may be brought to a smoother surface. The weight of a cubic foot is about 45 pounds.

1705. **CEDAR** (*Pinus Cedrus*) is an evergreen cone-bearing tree, of which though several have been grown in this country, it is too scarce to be employed in building. Its durability is very great; such, indeed, that Pliny states cedar to have been found in the Temple of Apollo at Utica, which must have been 1200 years old. Its colour is a light rich yellow brown, with the annual rings distinct. It is resinous, and has a powerful smell. The taste is slightly bitter, and it is not subject to worms. It is very straight in the grain, works easily and splits readily. Weight of a cubic foot from 30 to 38 pounds.

1706. **FIR** (*Pinus Sylvestris*). The red or yellow fir is produced on the hills of Scotland; but the forests of Russia, Denmark, Norway, Lapland, and Sweden produce the finest timber of this species. It is imported, under the name of red wood, in *logs* and *deals*. From Norway the trees are never more than 18 inches diameter, whence there is much saw-wood in them; but the heart is a stronger and more durable wood than is had from larger trees of other countries. From Riga a great deal of timber is received under the name of *masts* and *spars*: the former are usually 70 or 80 feet in length, and from 18 to 25 inches diameter; when of less diameter they take the latter name. Yellow deals and planks are imported from Stockholm, Frederickshall, Christiana, and various other parts of Sweden, Russia, Norway, and Prussia. Of the pine species the red or yellow fir is the most durable; and it was said by the celebrated Brindley, that red Riga deal, or pine wood, would endure as long as oak in all situations. In Pontey's *Forest Pruner*, on the authority of Dr. Smith, an instance is given of the durability of natural-grown Scotch fir. It is therein stated, that some was known to have been 300 years in the roof of an old castle, and that it was as fresh and full of sap as timber newly imported from Memel, and that part of it was actually wrought up into new furniture. It is to be observed, that foreign timber has an advantage too seldom allowed to that which is grown at home, the former being always in some degree seasoned before it arrives in this country, and therefore never used in so unseasoned a state as the latter timber usually is.

1707. From its great lightness and stiffness it is superior to any other material for beams, girders, joists, rafters, and framing in general. In naval architecture it is used for masts and various other parts of vessels. In joinery, both internal and external, it stands better, is nearly as durable as oak, and is much cheaper.

1708. There is great variety in the colours of the different sorts of this fir: it is generally of a red or honey yellow of different degrees of brightness, and consists in section of hard and soft circles alternately, one part of each annual ring being soft and light coloured, the

other harder and dark coloured, and possessing a strong resinous taste and smell. When not abounding in resin it works easily. That from abroad shrinks in the log, from seasoning, about one thirtieth part of its width.

1709. The annual rings of the best sort of this timber do not exceed one tenth of an inch in thickness, their dark parts are of a bright red colour. That from Norway is the finest of the sort, to which the best Riga and Memel are much inferior. The inferior timber of this kind, which is not so durable nor so capable of bearing strains, has thick annual rings, and abounds with a soft resinous matter, which is clammy and chokes the saw. Much of the timber of this sort is from Sweden, but it is inferior in strength and stiffness. That which is produced in the colder climates is superior to that which is the product of warmer countries, the Norway timber being much harder than that of Riga. The weight of a cubic foot of this fir, when seasoned, varies from 29 to 40 pounds. That of English growth, seasoned, from 28 to 33.

1710. WHITE FIR (*Pinus abies*), commonly called the spruce of Norway, whose forests produce it in abundance. This is the sort which in deals and planks is imported from Christiana, in which condition it is more esteemed than any other sort. The trees from which these are generally obtained are of 70 or 80 years' growth, and are usually cut into three lengths of about 12 feet each, which are sawn into deals and planks, each length yielding three deals or planks. Their most usual thickness is 3 inches, and they are generally 9 inches wide. In this country they are sold by the hundred, which in the case of white as well as yellow deals, contains 120 deals, be their thickness what it may, reduced to a standard one of an inch and a half, a width of 11 inches, and a length of 12 feet. What is called whole deal is an inch and a quarter thick, and slit deal is one half of that thickness. It unites better by means of glue than the yellow sort, is used much for interior work in joinery, and is very durable when in a dry state.

1711. The colour of the spruce fir is a yellow or rather brown white, the annual ring consisting of two parts, one hard, the other softer. The knots are tough, but it is not difficult to work. Besides the importation above named, there is a considerable quantity received from America. Of the Christiana fir a cubic foot weighs from 28 to 32 pounds when seasoned. That from America about 29 pounds; and the Norway spruce grown in Britain about 34 pounds. In seasoning it shrinks about a seventieth part, and after being purchased as dry deals at the timber yards, about one ninetieth.

1712. AMERICAN PINES. The *Pinus Strobus*, or what is called the Weymouth or white pine, is a native of North America, imported in logs often more than 2 feet square and upwards of 30 feet in length. It is an useful timber, light and soft, stands the weather tolerably well, and is much used for masts. For joiners' work it is useful from its clean straight grain. But it should not be used for large timbers, inasmuch as it is not durable, and is moreover very susceptible of the dry rot. Its colour is a brown yellow, and it has a peculiar odour. The texture is very uniform, more so, indeed, than any other of the pine species, and the annual rings are not very distinct. It stands well enough when well seasoned. A cubic foot of it weighs about 29 pounds.

1713. The yellow pine, or *Pinus variabilis*, is imported into England, but it is not much used; it is the produce of the pine forests from New England to Georgia.

1714. The pitch pine (*resinosa*), remarkable for the quantity and fragrance of the resin it produces, is a native of Canada. It is brittle when dry, and, though heavy, not durable. It is of a much redder hue than the Scotch pine, and from its glutinous property difficult to plane. The weight of a cubic foot is 41 pounds.

1715. The silver pine (*picea*) is common in the British plantations. This species of timber is produced in abundance, and is much used on the Continent both for carpentry and ship-building. It is light and stiff, and, according to Wiebeking, lasts longer in air than in water. A cubic foot weighs about 26 pounds.

1716. The Chester pine (*pinaster*) is occasionally cultivated in the British plantations. It is better suited to water than exposure to the air, and has a finer grain, but contains less resin, than the pine or silver fir. A cubic foot weighs about 26 pounds.

1717. LARCH (*Pinus Larix*). A timber tree only lately to any considerable extent adopted in the plantations of Great Britain, among whose cultivators the Duke of Athol has been one of the most ardent and successful. It grows straight and rapidly, is said to be durable in all situations, and appears to have been known and appreciated by Vitruvius, who regretted the difficulty of its transport to Rome, where, however, it was occasionally used. Wiebeking prefers it to the pine, pinaster, and fir, for the arches of timber bridges. To flooring boards and stairs, where there is much wear, it is well suited, and when oiled, assumes a beautiful colour, such, indeed, that when used for internal joinery, a coat of varnish gives it a more beautiful appearance than it could receive from any painting. The American larches do not produce turpentine; but the timber has been considered equal to the European sorts. It is of a honey yellow colour, and more difficult to work than the Riga or Memel timber, though, when obtained, the surface is better. It bears the driving

to nails and bolts, and stands well if properly seasoned. A cubic foot weighs from 30 of 40 pounds.

1718. **POPLAR.** The *Populus* of botanists, whereof five species are grown in England: the common white poplar, the black, the aspen or trembling poplar, the abele or great white poplar, and that of Lombardy. The wood of this tree is only fit for the flooring of inferior rooms where there is not much wear. Evelyn attributes to this wood the property of burning "untowardly," rather mouldering than maintaining any solid heat. Its colour is a yellow or brown white. The annual rings, whereof one side is a little darker than the other, making each year's growth visible, are of an uniform texture. The best sorts are the Lombardy, the black, and the common white poplar. Of the Lombardy poplar, the weight of a cubic foot is about 24 pounds; of the aspen and black poplar, 26 pounds; and of the white poplar, about 33 pounds.

1719. **ALDER** (*Betula alnus*). A tree delighting in wet places by the banks of rivers, and which furnished the material, says Vitruvius, for the piles whereon the whole of the buildings of Ravenna stand. In a dry situation it is unfit for employment, on account of its early rot when exposed to the weather or to mere damp, and its susceptibility of engendering worms. Evelyn says that it was used for the piles upon which the celebrated bridge of the Rialto at Venice was founded in 1591; but we have no certain data by which such assertion can be maintained. There is, however, no doubt that it may be advantageously employed in situations where it is constantly under water.

Its colour is of a red yellow, of different shades, but nearly uniform; which latter quality is exhibited in its texture.

From its softness it is easily worked, and seems adapted, therefore, for carving. In a dry state the weight of a cubic foot varies from 36 to 50 pounds.

1720. **ELM** (*Ulmus*). In Great Britain five species of this tree abound, whereof the *Ulmus campestris*, common in the woods and hedges of the southern parts of England, is a hard and durable wood, but is rarely used except for coffins. The *Ulmus suberosa*, or cork-barked elm, is an inferior sort, and is very common in Sussex.

1721. The *Ulmus Montana* is the most common species in Europe, and particularly in the northern counties of England. It is more generally known by the name of the broad-leaved elm or wych hazel. Without enumerating the other varieties, whereof the Dutch elm (*Ulmus major*) is good for nothing, we shall merely observe, that the *Ulmus glabra*, common in Herefordshire, Essex, and the north and north-eastern counties of England, grows to the largest size and is most esteemed, whilst the Dutch elm is the worst. The elm is a durable timber when constantly wet, as a proof whereof we have only to mention that it was used for the piles on which the old London Bridge stood. Indeed, its durability under water is well known; but for the general purposes of building it is of little value, and it rarely falls to the lot of the architect to be obliged to use it.

1722. The colour of the heart-wood is darker than that of oak, and of a redder brown. The sapwood is of yellow or brown-white colour. It is porous, cross and coarse grained, has a peculiar smell, twists and warps very much in drying, and shrinks considerably in breadth and length. Though difficult to work, it bears the driving of bolts and nails better than most other sorts of timber. The weight of a cubic foot, when dry, varies from 36 to 48, seasoned from 37 to 50 pounds. From experiment it seems that in seasoning it shrinks one forty-fourth part of its width.

1723. **ASH** (*Fraxinus excelsior*). This, the most valuable of the genus, is common throughout Europe and the northern parts of Asia. It grows rapidly, and of it the young is more valuable than the old wood. It is much affected by the difference of the soils in which it grows. It will not endure when subject to alternations of damp and moisture, though sufficiently durable when constantly in a dry situation. Its pores, if cut in the spring, are of a reddish colour, and it is improved by water-seasoning. Evelyn says, that when felled in full sap, the worm soon takes to it; and therefore recommends its being felled in the months from November to February. The texture is compact and porous, the compact side of the annual ring being dark in colour, whence the annual rings are distinct. The general colour is brown, resembling that of oak; but it is more veined, and the veins darker than those of oak. The timber of the young tree is a white, approaching brown, with a greenish hue. It has no peculiar taste or smell, is difficult to work, and is too flexible for use in building, beside the important want of the character of durability. The weight of a cubic foot varies from 35 to 52 pounds; and it is to be observed, when the weight is much less than 45 pounds the timber is that of an old tree.

1724. **SYCAMORE** (*Acer pseudo-platanus*), usually called the plane tree in the northern part of the island, is common in Britain and on the mountains of Germany. It is rapid in growth, and the wood is durable when it escapes the worm, to which it is quite as liable as beech. The use of it in buildings is not common, but for furniture it is valuable. The colour is a brown white, yellowish, and sometimes inclining to white. Texture uniform; annual rings indistinct. It is not so hard as beech, brittle, and generally easy to work. A cubic foot, when seasoned, weighs from 34 to 42 pounds. Ware says that there are old

houses in this country floored with sycamore and wainscotted with poplar. It seems well enough calculated for floors.

1725. BIRCH. *Betula alba*, or common birch, is a species of alder, to which article the reader is referred. (1719.)

1726. MAHOGANY (*Mahagoni*) has only three known species. That used (*Swietenia*) in England is a native of the West Indies, and the country round the Bay of Honduras in America. It was formerly abundant in the low lands of Jamaica, but is only found there, at present, on high hills and places difficult of access. It succeeds in most soils, though it varies in quality according to their natures. In rocky situations, though it does not attain so great a size, it is harder, weightier, of a closer grain, and more beautifully variegated than in low rich lands, whereon it is produced more porous, of paler colour, and of more open grain. It grows straight and lofty, and when full grown reaches a diameter of 5 feet. The flowers are of a red or saffron colour, and the fruit about the size of a turkey's egg. The wood is extremely hard, takes a fine polish, and is admirably adapted to articles of furniture. The expense of it in this country confines its use in building to doors, handrails of stairs, &c.; but in Jamaica it has been frequently used for floors, joists, rafters, shingles, &c.; and, indeed, ships have been built of it; for which last purpose, the circumstance of its allowing the shot to be buried without splintering makes it peculiarly suitable.

1727. The first use to which it was applied in this country was by a Mr. Wollaston in the ignoble service of a candle-box for a Dr. Gibbons, at the beginning of the last century (1724). With its appearance the doctor was so much pleased that he had a bureau afterwards made of it.

1728. The variety called Spanish mahogany, and imported from Cuba, Jamaica, Hispaniola, and other West India islands, comes in logs seldom more than 26 inches square, and about 10 or 12 feet in length, and is harder and closer grained than that from the Bay of Honduras, from which it may be distinguished, before it is oiled, by being of a lighter colour, and as if its pores were filled with a chalky matter. The Honduras mahogany has been latterly imported in logs of very large dimensions; we have ourselves seen one in the West India Docks which was 5 feet square, and upwards of 15 feet long. Its grain is very open generally, and often irregular, with black or grey spots. The veins are beautiful and of great variety. The best sort is that which is freest from grey specks and of a fine golden colour. It is held firmly with glue, perhaps, indeed, better than any other wood. A cubic foot of the best Jamaica mahogany weighs about 54 pounds; of Honduras, about 38 pounds.

1729. The teak and the African oak have latterly been imported into this country in considerable quantities. They are extremely hard and tough; but we do not, from the impossibility of their general use here, think it necessary to enter into any description of them. The following table, extracted from Rondelet's work, exhibits the mean heights of several sorts of trees, that of their trunks, their specific gravities and weight per cubic foot; in which latter column will be found some small differences from those already given, which may be accounted for from the variation in the qualities of the timber on which experiments were made.

Name of Tree.	Mean Height in English Feet.	Mean Height of Trunk in English Feet.	Diameter of Trunk in En- glish Inches.	Specific Gravity.	Weight of Cubic Foot in lbs. avoird.
Acacia - - -	26·65	12·79	10·66	789	47·74
Alder - - -	79·95	44·77	29·85	655	39·74
Almond tree - -	38·28	22·38	14·92	1102	66·74
Ash - - -	63·96	38·37	23·45	787	47·52
Beech - - -	76·72	44·77	27·72	720	43·63
Birch, common -	86·34	47·97	31·98	702	42·55
Box - - -	28·78	15·99	10·66	919	55·55
Cedar of Lebanon -	95·94	51·16	39·44	603	36·50
Chataignier (wild chesnut) -	76·72	44·77	27·71	685	41·47
Chesnut (sweet) Marronnier -	76·72	44·77	27·71	720	43·73
Cypress (pyramidal) -	76·72	38·37	27·71	655	39·74
Ebony of the Alps -	31·98	19·18	11·73	1054	63·72
Elm - - -	76·72	44·77	31·98	738	42·00
Fir - - -	102·32	57·56	46·90	542	31·92
Linden - - -	57·56	31·98	26·65	564	34·13
Oak (common of Canada) -	95·94	57·56	35·18	842	51·18
Oak (red of Virginia) -	86·34	47·97	31·98	587	35·42
Oak (common) -	86·34	44·77	31·98	905	54·69

Name of Tree.	Mean Height in English Feet.	Mean Height of Trunk in English Feet.	Diameter of Trunk in En- glish Inches.	Specific Gravity.	Weight of Cubic Foot in lbs. averd.

Yew - - -	28·78	15·99	10·66	778	47·09

1730. The preservation of timber, the prevention of decay, and the causes of decay, will require from us a succinct notice; and we shall commence by placing before the reader the observations on the subject from the celebrated and venerated Evelyn, though perhaps at the risk of repetition in what follows. As King Henry V. is made by Shakspeare to say of Fluellen, "Though it appear a little out of fashion, there is much care in this" author.

1731. "Lay up your timbers very dry, in an airy place, yet out of the wind or sun, and not standing very upright, but lying along, one piece upon another, interposing some short blocks between them, to preserve them from a certain mouldiness which they usually contract while they sweat, and which frequently produces a kind of fungus, especially if there be any sappy parts remaining.

1732. "Some there are yet who keep their timber as moist as they can by submerging it in water, where they let it imbibe, to hinder the cleaving; and this is good in fir, both for the better stripping and seasoning; yea, not only in fir, but other timber. Lay, therefore, your boards a fortnight in the water (if running the better, as at some mill-pond head); and there, setting them upright in the sun and wind, so as it may freely pass through them (especially during the heats of summer, which is the time of finishing buildings), turn them daily; and thus treated, even newly sawn boards will floor far better than many years' dry seasoning, as they call it. But, to prevent all possible accidents, when you lay your floors, let the joints be shot, fitted, and tacked down only for the first year, nailing them for good and all the next; and by this means they will lie staunch, close, and without shrinking in the least, as if they were all one piece. And upon this occasion I am to add an observation, which may prove of no small use to builders, that if one take up deal boards that may have lain in the floor a hundred years, and shoot them [plane their edges] again, they will certainly shrink (*toties quoties*) without the former method. Amongst wheelwrights the water seasoning is of especial regard, and in such esteem amongst some, that I am assured the Venetians, for their provision in the arsenal, lay their oak some years in water before they employ it. Indeed, the Turks not only fell at all times of the year, without any regard to the season, but employ their timber green and unseasoned; so that though they have excellent oak, it decays in a short time, by this only neglect.

1733. "Elm felled ever so green, for sudden use, if plunged four or five days in water (especially salt water), obtains an admirable seasoning, and may immediately be used. I the oftener insist on this water seasoning, not only as a remedy against the worm, but for its efficacy against warping and distortions of timber, whether used within or exposed to the air. Some, again, commend burying in the earth; others in wheat; and there be seasonings of the fire, as for the scorching and hardening of piles, which are to stand either in the water or in the earth.

1734. "When wood is charred it becomes incorruptible; for which reason, when we wish to preserve piles from decay, they should be charred on their outside. Oak posts used in enclosures always decay about two inches above and below the surface. Charring that part would probably add several years to the duration of the wood, for that to most timber it contributes its duration. Thus do all the elements contribute to the art of seasoning.

1735. "Timber which is cleft is nothing so obnoxious to reft and cleave as what is hewn; nor that which is squared as what is round: and therefore, where use is to be made of huge and massy columns, let them be bored through from end to end. It is an excellent preservative from splitting, and not unphilosophical; though to cure the accident painter's putty is recommended; also the rubbing them over with a wax cloth is good; or before it be converted the smearing the timber over with cow-dung, which prevents the effects both of sun and air upon it, if of necessity it must lie exposed. But, besides the former remedies, I find this for the closing of the chops and clefts of green timber, to anoint and supple it with the fat of powdered beef broth [we do not quite agree with our author here], with which it must be well soaked, and the chasms filled with sponges dipped into it. This to be twice done over.

1736. "We spake before of squaring; and I would now recommend the quartering of such trees as will allow useful and competent scantlings to be of much more durableness and effect for strength, than where (as custom is and for want of observation) whole beams and timbers are applied in ships or houses, with slab and all about them, upon false suppositions of strength beyond these quarters.

1737. "Timber that you have occasion to lay in mortar, or which is in any part contiguous to lime, as doors, window cases, groundsils, and the extremities of beams, &c., have sometimes been capped with molten pitch, as a marvellous preserver of it from the burning and destructive effects of the lime; but it has since been found rather to heat and decay them, by hindering the transudation which those parts require; better supplied with loam, or strewings of brick-dust or pieces of boards; some leave a small hole for the air. But though lime be so destructive, whilst timber thus lies dry, it seems they mingle it with hair to keep the worm out of ships, which they sheathe for southern voyages, though it is held much to retard their course.

1738. "For all uses, that timber is esteemed the best which is the most ponderous, and which, lying long, makes the deepest impression in the earth, or in the water being floated; also what is without knots, yet firm and free from sap, which is that fatty, whiter, and softer part called by the ancients *albumen*, which you are diligently to hew away. My Lord Bacon (Exper. 658.) recommends for trial of a sound or knotty piece of timber, to cause one to speak at one of the extremes to his companion listening at the other; for if it be knotty, the sound, says he, will come abrupt."

#### PRESERVATION OF TIMBER.

1739. The preservation of timber, when employed in a building, is the first and most important consideration. Wherever it is exposed to the alternations of dryness and moisture, the protection of its surface from either of those actions is the principal object, or, in other words, the application of some substance or medium to it which is impervious to moisture; but all timber should be perfectly dry before the use of the medium. In Holland the application of a mixture of pitch and tar, whereon are strewn pounded shells, with a mixture of sea sand, is general; and with this, or small and sifted beaten scales from a blacksmith's forge, to their drawbridges, sluices, and gates, and other works, they are admirably protected from the effects of the seasons. Semple, in his work on aquatic building, recommends, that "after your work is tried up, or even put together, lay it on the ground, with stones or bricks under it to about a foot high, and burn wood (which is the best firing for the purpose) under it, till you thoroughly heat, and even scorch it all over; then, whilst the wood is hot, rub it over plentifully with linseed oil and tar, in equal parts, and well boiled together, and let it be kept boiling while you are using it; and this will immediately strike and sink (if the wood be tolerably seasoned) one inch or more into the wood, close all the pores, and make it become exceeding hard and durable, either under or over water." Semple evidently supposes the wood to have been previously well seasoned.

1740. Chapman (on the preservation of timber) recommends a mixture of sub-sulphate of iron, which is obtained in the refuse of copperas pans, ground up with some cheap oil, and made sufficiently fluid with coal-tar oil, wherein pitch has been infused and mixed.

1741. For common purposes, what is called *sanding*, that is, the strewing upon the painting of timber, before the paint dries, particles of fine sand, is very useful in the preservation of timber.

1742. Against worms we believe nothing to be more efficacious than the saturation of timber with any of the oils; a process which destroys the insect if already in the wood, with that of turpentine especially, and prevents the liability to attack from it. Evelyn recommends nitric acid, that is, sulphur immersed in aquafortis and distilled, as an effectual application. Corrosive sublimate, lately introduced under Kyan's patent, has long been known as an effectual remedy against the worm. Its poisonous qualities of course destroy all animal life with which it comes in contact; and we believe that our readers who are interested in preserving the timbers of their dwellings may use a solution of it without infringing the rights of the patentee. But the best remedy against rot and worms is a thorough introduction of air to the timbers of a building, and their lying as dry and as free from moisture as practicable. Air holes from the outside should be applied as much as possible, and the ends of timbers should not, if it can be avoided, be bedded up close all round them. This practice is, moreover, advisable in another respect, that of being able, without injury to a building, to splice the ends of the timbers should they become decayed, without involving the rebuilding of the fabric; a facility of no mean consideration.

1743. The worm is so destructive to timber, both in and out of water, that we shall not apologise for closing this part of our observations with Smeaton's remarks upon a species of worm which he found in Bridlington piers. "This worm appears as a small white soft substance, much like a maggot; so small as not to be seen distinctly without a magnifying glass, and even then a distinction of its parts is not easily made out. It does not attempt

to make its way through the wood longitudinally, or along the grain, as is the case with the common ship worm, but directly, or obliquely, inward. Neither does it appear to make its way by means of any hard tools or instruments, but rather by some species of dissolvent liquor furnished by the juices of the animal itself. The rate of progression is, that a three inch oak plank will be destroyed in eight years by action from the outside only." For resisting the effects of these worms, Smeaton recommends the piles to be squared, to be fitted as closely as possible together, and to fill all openings with tar and oakum, to make the face smooth, and cover it with sheathing.

1744. The destructive effects of the white ant are so little known here, that it is unnecessary to make further mention of them, than that in India they are the most inveterate enemies with which timber has to contend. From *Young's Annals* we extract the following curious statement of experiments made upon inch and a half planks, from trees of thirty to forty-five years' growth, after an exposure of ten years to the weather.

Cedar was perfectly sound.	Chesnut, very sound.
Larch, sap quite decayed, but the heart, sound	Abele, sound.
Spruce fir, sound.	Beech, ditto.
Silver fir, in decay.	Walnut, decayed.
Scotch fir, much decayed.	Sycamore, considerably decayed.
Pinaster, in a perfectly rotten state.	Birch, worthless.

Whence we may be led to some inference of the value of different sorts of timber in resisting weather; though we must not be altogether guided by the above table, inasmuch as it is well known that the soil on which timber is grown much increases or deteriorates its value, and that split timber is more durable and stronger than that which is sawn, from the circumstance of the fibres, on account of their continuity, resisting by means of their longitudinal strength; whereas when severed by the saw, the resistance depends more on the lateral cohesion of the fibres. Hence whole trees are invariably stronger than specimens, unless these be particularly well selected, and of a straight and even grain; but in practice the results of experiments are on this account the more useful.

#### DECAY OF TIMBER.

1745. If timber, whatever its species, be well seasoned, and be not exposed to alternate dryness and moisture, its durability is great, though from time it is known to lose its elastic and cohesive powers, and to become brittle if constantly dry. On this account it is unfit, after a certain period, to be subjected to variable strains: however, in a quiescent state it might endure for centuries. Dryness will, if carried to excess, produce this category. The mere moisture it absorbs from the air in dry weather is not sufficient to impair its durability. So, also, timber continually exposed to moisture is found to retain for a very long period its pristine strength. Heat with moisture is extremely injurious to it, and is in most cases productive of rot, whereof two kinds are the curse of the builder, the *wet* and the *dry* rot, though perhaps there be but little difference between the two. They appear to be produced by the same causes, excepting that the freedom of evaporation determines the former, and an imperfect evaporation the latter. In both cases the timber is affected by a fungus-like parasite, beginning with a species of mildew; but how this fungus is generated is still a *vezata questio*; all we know is, that its vegetation is so rapid, that often before it has arrived at its height, a building is ruined. From our inquiries on the Continent, we believe the disease does not occur to the extent that it does in this country; a fact which we are inclined, perhaps erroneously, to attribute to the use of the timber of the country, instead of imported timber. Our opinion may be fanciful, but there are many grounds on which we think that is not altogether the case. Our notion is, that our imported timber is infected with the seeds of decay long before its arrival here (we speak of fir more especially), and that the comparative warmth and moisture of the climate bring more effectually the causes of decay into action, especially where the situation is close and confined. Warmth is, doubtless, known to be a great agent in the dry rot, and most especially when moisture co-operates with it, for in warm cellars and other close and confined situations, where the vapour which feeds the disease is not altered by a constant change of air, the timbers are soon destroyed, and become perfectly decomposed.

1746. The lime, and more especially the damp brickwork, which receive the timbers of a new building, are great causes of decay to the ends of them; but we do not think that the regulations of the 19 Car. II. cap. 3., which directed the builders, after the fire of London, to bed the ends of their girders and joists in loam instead of mortar, would, if followed out in the present day, be at all effective in preventing the decay incident to the ends of timbers. Timber, in a perfectly dry state, does not appear to be injured by dry lime; and, indeed, lime is known to be effectual in the protection of wood against worms.

1747. Nothing is more injurious to the floors of a building than covering them with

painted floorcloth, which entirely prevents the access of atmospheric air, whence the dampness of the boards never evaporates; and it is well known that oak and fir posts have been brought into premature decay by painting them before their moisture had evaporated; whilst in the timber and pewing of old churches, which have never been painted, we see them sound after the lapse of centuries. Semple, in his *Treatise on Building in Water* notices an instance of some field gates made of the fir of the place, part whereof, near the mansion, were painted, and had become rotten, while those more distant from the mansion, which had never been painted, were quite sound.

#### PREVENTION OF DECAY.

1748. After timber is felled, the best method of preventing decay is the immediate removal of it to a dry situation, where it should be stacked in such a manner as to secure a free circulation of air round it, but without exposure to the sun and wind, and it should be rough squared as soon as possible. When thoroughly seasoned before cutting it into scantlings, it is less liable to warp and twist in drying. The ground about its place of deposit should be dry and perfectly drained, so that no vegetation may rise on it. Hence a timber yard should be strewed with ashes, or the scales from a foundry or forge, which supply an admirable antidote to all vegetation. It is thought that the more gradually timber is seasoned the greater its durability; and, as a general rule, it may be stated, that it should not be used till a period of at least two years from its being felled, and for joiners' work at least four years. Much, however, is dependent on the size of the pieces. By some, water seasoning has been recommended; by others, the steaming and boiling it; smoke-drying, charring, and scorching have also been recommended. The latter is, perhaps, the best for piles and other pieces that are to stand in the water or in the ground. It was practised by the ancients, and is still in use generally for the posts of park paling and the like.

1749. In Norway the deal planks are seasoned by laying them in salt water for three or four days, when newly sawed, and then drying them in the sun, a process which is considered to be attended with advantage; but it does not prevent their shrinking. Mr. Evelyn recommends the water seasoning for fir, but we incline to think that gradual dry seasoning is the best method.

1750. Notwithstanding, however, all care in seasoning, when timber is employed in a damp situation it soon decays; and one of the principal remedies against that is good drainage, without which no precautions will avail. It is most important to take care that earth should not lie in contact with the walls of a building, for the damp is quickly communicated, in that case, by their means to the ends of timbers, and rot soon follows. No expedient to guard against this contingency is so good as what are called air or dry drains, which are areas formed by thin walls round the building, with apertures in the paving laid between them and the principal walls, so as to afford a constant current of fresh air.

1751. When the carcass of a building is complete, it should be left as long as possible to dry, and to allow to the timbers what may be called a second seasoning. The modern practice of finishing buildings in the quickest possible period, has contributed more to dry rot than perhaps any other cause; and for this the architect has been blamed instead of his employer, whose object is generally to realize letting or to enjoy occupation of them as early as possible. After, however, the walls and timbers of a building are once thoroughly dry, all means should be employed to exclude a fresh accession of moisture, and delay becomes then prejudicial.

1752. We have before noticed corrosive sublimate in solution as a wash useful in the prevention of decay, and have also ourselves found that a weak solution of vitriolic acid with water will generally stop the rot if it have not gone too far. But it is extremely difficult to prevent the spreading of the fungus of the dry rot after it has once commenced; and the precautions indicated above, although not always successful, are better than the being reduced to after remedies. Certain, however, it is, that the washes we have named will often prevent the infection from spreading. Pyroligneous acid has recently been recommended, and, we think, very usefully, as a remedy for preventing the spreading of the disease.

#### CURE OF ROT.

1753. It is no easy matter to cure the rot where it has once taken root. If it be found necessary to substitute new timbers for old ones, every particle of the fungus must be removed from the neighbourhood of such new timbers. After scraping it from the adjoining walls and timbers, perhaps no better application than one of the washes above mentioned can be employed, inasmuch as they can always be with safety applied to the parts. An extraordinary degree of heat would effect the same purpose, but this, especially in the case of floors, is difficult in application. Coal tar has been found useful, but its extremely unpleasant odour is an objection.

## SECT. V.

## IRON.

1754. Iron is a metal found in almost all parts of the world, and though not mentioned by Homer, and hence, we may suppose, in his time extremely scarce, it is now more abundant than any of the other metals, and is, at the same time, the most useful. Although, with the exception of tin, it is the lightest of all metals; yet it is, when pure, very malleable and extremely hard. Its malleability is increased by heat, whereas most other metals, as they are heated, become more brittle. It is the only known substance whereon the loadstone acts, and its specific gravity to water is as 7632 to 1000.

1755. The iron manufactured in Great Britain is obtained from three species of the ore. The *Lancashire*, which is very heavy, fibrous in texture, and of a dark purple colour inclining to black, and lodged in veins. The *Bog ore*, which has the appearance of a deep yellow clay, and is found in strata of from twelve to twenty inches in thickness. And lastly, *Iron stones*, of an irregular shape, frequently in beds of large extent, similar to other stony masses, and often intersected with seams of pit coal. It is principally from the argillaceous ore or clay iron-stone that iron is extracted in this country.

1756. After raising, the ores are selected and separated as much as possible from heterogeneous substances. They are then roasted in large heaps in the open air, for the purpose as well of freeing them from the arsenic and sulphur they contain as to render them friable or easy of reduction to a powder. The roasting is performed by means of bituminous coal, and the result is a substance full of fissures, friable, and a deprivation of all vitreous lustre. After this it is transferred to the crushing mill for complete pulverization, whence it is carried to the smelting furnace for conversion into iron. Herein it undergoes two separate processes: first, the reduction of the oxide to a metallic state; second, the separation of the earthy particles in the form of scoria. These operations are conducted by submitting the ore, ordinarily mixed with certain fluxes, to the action of carbon at a very high temperature, in what are called blast furnaces, which vary in height from twelve to sixty feet, and are of the form of truncated cones, sometimes however of pyramids, terminating usually in cylindrical chimneys, whose internal diameter is from four to six feet. The interior of these furnaces is usually of a cylindrical form, whose internal diameter is from four to six feet. Their cavity is usually of a circular form, except at the *crucible* or *hearth*, where it becomes a right rectangular prism, oblong in a direction perpendicular to the blast orifices or *tuyeres* of the bellows. The sides of the crucible are most commonly formed of gritstone. The *boshes*, which are in the form of an inverted quadrangular pyramid approaching a prismatic shape, are placed above the crucible, and above them rises the conical body of the furnace, which is lined with fire-bricks, and, in ascending, is contracted similarly to the narrow end of an egg, until it terminates in the chimney. The furnace is of course constructed in the most solid manner, and strengthened by iron bands and bars. The bellows employed are mostly of a cylindrical form, and their pistons worked either by water or steam. The blast holes, which are in the upper part of the crucible, and frequently placed on opposite sides, but so that the two opposite currents may not impinge upon one another, are two in number. Openings are provided at the lower part of the crucible for the discharge of the metal and scoria, and are kept stopped by clay and sand upon the exterior when the furnace is in operation. The reduction is commenced by gradually heating up the furnace until capable of being entirely filled with fuel, and then, as its contents begin to sink, alternate changes of ore, mingled with *flux*, and of charcoal and coke, are added. The blast is now let on, and the metal in the ore, parting with its oxygen, flows by degrees, subsiding to the bottom of the crucible, covered with a melted *slag*, which is occasionally let off by removing the clay from one or more, if necessary, apertures in the crucible; and on the bottom of the furnace becoming filled with the metal, which generally occurs after nine to twelve hours, the iron itself is discharged by one of these openings into a fosse of sand mixed with clay. When the iron has flowed out the aperture is again closed, and by this method the furnace is kept in constant action.

1757. Limestone of the best quality is employed as a flux to assist the fusion of the ore, which it accomplishes by vitrefying the earths wherewith it is mixed up with the oxide of iron. The iron when run out from the blast furnace in the state of cast iron is far from being in a pure state, having a coarse grain, and being brittle. In its conversion to bar iron, it undergoes one of the two following processes, as charcoal or coke may be employed. In the former case a furnace much resembling a smith's hearth is used, having a sloping cavity sunk from ten to twelve inches below the blast pipe. After the cavity has been filled with charcoal and scoria, a pig of cast iron, well covered with hot fuel, is placed opposite the blast pipe. The blast being introduced, the pig of iron lying in the very hottest part soon begins to melt, and runs down into the cavity below, where, being out of the influence of the blast, it becomes solid, and is replaced in its former position, and the

cavity is again filled with charcoal. It is there again fused, and so on a third time, all these processes being accomplished in three or four hours. The iron, thus again solid, is taken out, and very slightly hammered, to free it from the attached scoria; after this it is returned to the furnace, in a corner whereof it is stacked, out of the action of the blast, and well covered with charcoal, where it remains gradually to cool until sufficiently compact to bear the *tilt*, or *trip hammer*, which is moved by machinery, and whose weight is from 600 to 1200 lbs. Thus it is beaten till the scoræ are forced out, when it is divided into several portions, which, by repeated heating and hammering, are drawn into bars, in which state it is ready for sale.

1758. There are various methods of procuring the blast, which we think it unnecessary here to detail: the first, and most ancient, are by means of bellows; the latest, which has been found in the mining districts to be a contrivance of great importance, is the placing a series of vanes attached to an axis, which are made to revolve in a box with great rapidity. A pipe passing from the outside of the box to the furnace conveys the air to it as the vanes revolve, a new portion continually entering by a hole at the axis.

1759. The proportion of pig or cast iron from a given quantity of ore varies as the difference in the metallic contents of different parcels of ore and other circumstances, but the quantity of bar obtained from pig iron is not valued at more than 20 per cent.

1760. The other process for manufacturing bar iron, which is that chiefly employed in this country, is conducted in reverberatory furnaces, usually called *puddling furnaces*. The operation begins with the fusion of the cast iron in refinery furnaces, like the one above described. When the iron is fully melted, a tap-hole is opened in the crucible, and the metal and slag flow out together into a fosse covered with clay well mixed with water, by which a coating is formed that prevents the metal from sticking to the ground. The finer metal forms a slab about ten feet long, three feet broad, and from two to two and a half inches in thickness. For the purpose of slightly oxidizing it, and to make it brittle, it is much sprinkled over with cold water. In this part of the process it loses in weight from 12 to 17 per cent. After this, it is broken up into pieces, and placed on the hearth of a reverberatory furnace, in portions heaped up to its sides in piles which rise nearly to the roof, leaving a space open in the middle to give room for puddling the metal as it flows down in streams. When the heat of the furnace has brought it to a pasty state, the temperature is reduced, a little water being sometimes thrown on the melted mass. The semi-liquid metal is stirred up by the workman with his *puddle*, during which it swells, and parts with a large quantity of oxide of iron, which burns with a blue flame, so that the mass appears ignited. As it refines, the metal becomes less fusible, or, as the workmen say, it begins to *dry*. The puddling goes on until the whole charge assumes the form of an incoherent sand, when the temperature is gradually increased to give it a red white heat, at which period the particles begin to agglutinate, and the charge, in technical language, *works heavy*. The refining is now considered finished, and the metal has only to be formed into balls, and condensed under the rolling cylinder. From this state it is brought into *mill bar iron*. After this last operation, several pieces are welded together, from which it acquires ductility, uniformity, and cohesion. A lateral welding of four pieces together now follows, and the mass passes through a series of cylinders as in the first case, and becomes English bar-iron.

1761. The lamination of iron into sheets is by a refinery furnace, with a charcoal instead of a coke fire.

1762. Malleable iron is often obtained from the ores directly, by one fusion, if the metallic oxide be not too much mixed with foreign substances. It is a mode of working much more economical than that above described, and from the circumstance of its having been long known and used in Catalonia, it is known by the name of the *method of the Catalonian forge*. The furnace employed is similar to the refiner's forge already described. The crucible is a kind of semicircular or oblong basin, eighteen inches in diameter, and eight or ten in depth, excavated in an area, or small elevation of masonry, eight or ten feet long, by five or six broad, and covered in with a chimney. The tuyere is placed five or six inches above the basin, inclining a little downwards, and the blast is received from a water blowing machine. The first step consists in expelling the water combined with the oxide, as well as the sulphur and arsenic when these are present. This, as usual, is done by roasting in the open air, after which it is reduced to a tolerably fine powder, and thrown at intervals by shovels full upon the charcoal fire of the forge hearth, the sides and bottom of the basin being previously lined with *brasques* (coats of pounded charcoal). It gradually softens and unites into lumps more or less coherent, which finally melt and accumulate in the bottom of the crucible or basin. A thin slag is occasionally let off from the upper surface of the melted metal in the basin through holes which can be closed and opened at the discretion of the workman. The melted iron preserves a pasty condition owing to the heat communicated from above. When a mass sufficiently great has accumulated, it is removed, put under the hammer, and forged at once. A lump, or bloom, of malleable iron is thus produced in the space of three or four hours. Four workmen are employed at one

forge, and by being relieved every six hours, they are enabled to make 86 cwt. of iron per week. In the Catalonian forge, 100 lbs. of iron are obtained from 300 lbs. of ore (a mixture of sparry iron, or carbonate and hemalite), and 310 lbs. of charcoal, being a produce of 33 per cent.

1763. A visit to some of the iron districts is necessary fully to understand the processes we have above shortly described; but the founding of iron may be well enough observed in the metropolis, though not on so large a scale as in some of the provinces.

1764. The sand employed in casting is of a soft yellow and clammy nature, over which, in the mould, charcoal is strewed. Upon the sand properly prepared, the wood or metal models of what is intended to be cast are applied to the mould, and pressed so as to leave their impression upon the sand. Canals are provided for the metal, when melted, to run through. After the frame is finished, the patterns are taken out by loosening them all round, that the sand may not give way. The other half of the mould is then worked with the same patterns, in a similar frame, but having pins which, entering into holes that correspond to it in the other, cause the two cavities of the pattern exactly to fall on each other. The frame thus moulded comes now under the care of the melter, who prepares it for the reception of the metal.

1765. All castings should be kept as nearly as possible of the same bulk, in order that the cooling may take place equably. It is of importance to prevent air bubbles in castings, and the more time there is allowed for cooling the better, because when rapidly cooled, the iron does not become so tough as when gradually cooled.

1766. In making patterns for cast iron, an allowance should be made of about one eighth of an inch per foot for the contraction of the metal in cooling. And it may be also requisite that the patterns should be slightly bevelled, that they may be drawn out of the sand without injuring the impression; for this purpose a sixteenth of an inch in six inches is sufficient.

1767. The security afforded, not only for supporting weight, but against fire, has, of late years, very much increased the use of it, and may in many cases entirely supersede the use of timber. Again, it is valuable from its being not liable to sudden decay, nor soon destroyed by wear and tear, and, above all, from its plasticity.

1768. Soft grey cast iron is the best sort; it yields easily to the file when the external crust is removed, and is slightly malleable in a cold state. It is, however, more subject to rust than the white cast iron, which sort is also less soluble in acids. Hence the white sort may be employed where hardness is necessary and brittleness not a defect. Grey cast iron has a granulated fracture with some metallic lustre, and is much softer and tougher than the white cast iron. The white cast iron in a recent fracture has a white and radiated appearance, indicating a crystalline structure.

1769. The most certain test of the goodness of a piece of cast iron is by striking the edge with a hammer, which if it make a slight impression, denoting some degree of malleability, the iron is of a good quality. It is important in any casting to have the metal as uniform as possible, and not of different sorts, for different sorts will shrink differently, and thus will be caused an unequal tension among the parts of the metal, which will impair its strength: and, beyond this, an unevenness is produced by such mixture in the casting, for different sorts can never be perfectly blended together. (See 1797.)

1770. It is well known, also, that iron varies in strength, not only in samples from different furnaces, but even from the same furnace and the same melting. This, however, seems owing to some imperfection in the casting, notwithstanding which, it is, when well mixed, capable of resisting the greatest stresses in mill and engine work.

1771. The transverse strength of cast iron, as of any other body, is that power which it exerts in opposing a force acting in a direction perpendicular to its length, as in the case of beams, levers, and the like. It is well known that the transverse strengths of beams, &c. are inversely as their lengths, and directly as their breadths and the squares of their depths. If cylinders, that they are as the cubes of their diameters. Thus, if a beam 6 feet long, 2 inches broad, and 4 inches deep, will bear 5000 lbs., another of the same scantling, and double the length, will only bear 2500 lbs., being inversely as the lengths. So, if a beam 6 feet long, 2 inches broad, and 4 inches deep will support a weight of 5000 lbs., another beam of the same material, twice the breadth, that is, 4 inches, will support 10,000 lbs., that is, double, being directly as the breadths; but a beam of the same material 6 feet long, 2 inches broad, and 8 inches deep, will sustain 20,000 lbs., being as the squares of their depths. From a mean of several experiments on cast iron, it may be assumed that the ultimate or breaking strength of a bar of cast iron 1 inch square and 1 foot long, loaded in the middle, was 2580 lbs.; and taking one third, or 860 lbs., as the weight which will not destroy its elasticity, we thus obtain constants for guiding us in the ordinary computations for the sizes of girders, beams, bresssummers, &c. The strongest form of the section of a beam to resist a cross strain is this  $\text{III}$ . We do not however think it here necessary to give much more than the rules for finding their breadths and depths, considered as simple figures. The principles on which the rules subjoined are founded may be seen in Gregory's *Me-*

chanics, and Barlow *On the Strength of Materials*, but divested, certainly, of the refinement of Dr. T. Young's *Modulus of Elasticity*, and some other matters, which we cannot help thinking unnecessary in a subject where, after exhausting all the niceties of the question, a very large proportion of weight is still considered too much for the constant load to be imposed on the examples.

1772. PROBLEM I. To find the ultimate strength of a rectangular beam of cast iron supported at both ends, and loaded in the middle, we have only to multiply the breadth into the square of the depth, and that again by the constant 2580, and the last product divided by the length in feet will be a quotient expressing the weight in pounds averdupois, nearly.

Example. What weight will break a cast iron beam 2 inches broad, 6 inches deep, and 15 feet between the supports?

$$\text{Here } \frac{2580 \times 2 \times 6^2}{15} = 12384 \text{ lbs.}$$

If a beam be supported at the middle and loaded at each end, it will bear the same weight as when supported at both ends and loaded in the middle. It may be here observed, that the following rules hold good for inclined as well as horizontal beams, if the horizontal distance between the supports be taken for the bearing.

1773. PROBLEM 2. To find the ultimate strength of a cast-iron beam when the weight is placed somewhere between the middle and the end. Multiply twice the length of the longer end by twice the length of the shorter end, which divided by the whole length will give the effectual length. Using the effectual length thus found as the length in Problem 1., the question may be answered.

Example. What is the ultimate strength of a cast iron beam 15 feet between the supports, 2 inches wide, and 6 inches deep, the weight being placed at 5 feet from one end?

$$\text{Here } \frac{(2 \times 10) \times (2 \times 5)}{15} = 13.33 \text{ effective length, and } \frac{2580 \times 2 \times 6^2}{13.33} = 13934 \text{ lbs.}$$

In the case of any beam fixed at one end and loaded at the other, it is known that it will bear only one fourth of the weight it will bear in the middle when supported at both ends. Thus for

Example. What weight will break a cast iron beam 2 inches wide and 6 inches deep, projecting 15 feet from the point of support?

$$\text{Here } \frac{2580 \times 2 \times 6^2}{15} = \frac{12384}{4} = 3096 \text{ lbs. (See Prob. 1.)}$$

1774. The above rules are equally applicable to beams whose forms are cylindrical, except that in such case the absolute strength of a round bar (for which in that of cast iron the constant is for the breaking weight 2026, one third whereof is 675 for cast iron) is found by multiplying by the cube of the diameter instead of by the breadth and square of the depth.

Example. What is the ultimate transverse strength of a cast iron cylinder 15 feet long and 6 inches diameter?

$$\text{Here } \frac{2580 \times 6^3}{15} = 37152 \text{ lbs.}$$

In the case of a hollow shaft of cast iron of the same length as in the last example, whose diameter is 9 inches, but whose cross sectional area is the same as a solid cylinder 6 inches diameter,

$$\text{We have } \sqrt{9^2 - 6^2} = 6.708, \text{ and } 9^3 - 6.708^3 = 426.9.$$

$$\text{Then } \frac{2580 \times 426.9}{15} = 73,427 \text{ lbs.}$$

1775. The following points relative to loads on beams are to be here noted. I. If any beam be fixed at both ends, when loaded in the middle, it is capable of bearing one half more than it will if both ends are loose. II. If loose at both ends, and the weight be applied uniformly along its length, it will support double. III. If it be fixed at both ends, and the weight be applied uniformly along its length, it is capable of bearing triple the weight.

1776. In cases where beams of cast iron are intended to support a permanent weight, the application of the following problem is necessary, in which 860, or one third of the breaking weight, is used.

1777. PROBLEM III. To find the breadth or depth of beams which shall support a given permanent weight. The length between the supports must be multiplied by the weight to be supported in pounds, and the product divided by one third (860) of the ultimate strength of an inch bar multiplied by the square of the depth, and the quotient will be the breadth. If multiplied by the breadth, the quotient will be the square of the depth, both in inches.

Example. What should be the breadth of a cast iron beam 15 feet long and 6 inches deep, to support 3 tons in the middle? (3 tons = 6720 lbs.)

Here  $\frac{6720 \times 15}{860 \times 6^2} = 3.25$  inches, full.

**Example.** What depth should be given to a cast iron beam 3.25 inches broad and 15 feet long, to bear a permanent weight of 3 tons in the middle?

Here  $\frac{6720 \times 15}{860 \times 3.25} = 36.06$ , whose square root is 6 inches.

**Example.** Suppose a cast iron beam 15 feet long and 6 inches deep, made fast at both ends, to be loaded with a permanent weight of 3 tons in the middle, what should be its breadth?

Here, from the last problem,  $\frac{6720 \times 15}{860 \times 6^2 \times 1.5} = 2.17$  inches.

A beam when fixed at one end and loaded at the other is known to bear only one fourth of the weight; one quarter of the divisor must therefore be taken, or, which is the same, it may be multiplied by .25.

**Example.** What should be the depth of a beam 3 inches broad, to project 10 feet from a wall, and to be loaded with a weight of 3 tons = 6720 lbs.?

Here  $\frac{6720 \times 10}{860 \times 3 \times .25} = 104$ , whose square root = 10.19 inches.

When the weight is not placed in the middle of the beam, the effective length must be obtained as in Problem 1.

**Example.** What depth should be assigned to a cast iron beam 15 feet long and 3 inches broad, to support a weight of 3 tons = 6720 lbs., 5 feet from one end?

Here  $\frac{(2 \times 10) \times (2 \times 5)}{15} = 13.33$ , effective length of the beam.

And  $\frac{6720 \times 13.33}{860 \times 3} = 34.7$ , whose square root 5.9 inches, nearly.

The strength of cast iron to wrought iron is as 9 to 14, nearly.

N.B. All the above rules may be applied in common practice to find the scantlings of beams by using the following factors instead of that of cast iron, such factors being the ultimate transverse strengths of a bar 1 inch square and 1 foot long of the different sorts of timber to which they are attached.

Ash	-	-	1137, one third whereof is 379
Pitch pine	-	-	916 — 305
Oak	-	-	800 — 209
Elm	-	-	569 — 149.
Fir	-	-	566 — 148

1778. The greatest variable load on a floor, except in public rooms, seldom exceeds 120 lbs. to the square foot, whence the reader may form a pretty accurate notion of the quantity of strain against which he has to provide.

1779. The cohesive strength of cast iron, from some of the latest experiments, was found in horizontal casting to be equal to 18,656 lbs. per square inch, and in vertical casting 19,488 lbs. to the square inch. One third, therefore, of 18,656 = 6219 may be used as the factor in computations of the permanent cohesive strength of cast iron. In English wrought iron the experiment gives 55,872 lbs. for the cohesive strength per square inch of English wrought iron, and for Swedish, 72,064 lbs. per square inch. If, therefore, it be required to find the ultimate cohesive strength of bars of cast or wrought iron, the area of their section being found, and multiplied by the relative cohesive strengths above mentioned, the product will be the ultimate cohesive strength, nearly. Thus for

**Example.** What is the cohesive power of a bar of cast iron  $1\frac{1}{2}$  inch square?

Here  $1.5 \times 1.5 \times 18656 = 41976$  lbs., nearly.

If the weight to be sustained be given, and the sectional dimensions of the bar be required, we must divide the weight given by one third of the cohesive strength of an inch bar, and the square root of the quotient will be the side of the square.

**Example.** What dimension must be given to the side of a square bar of Swedish iron to sustain a permanent weight of 18,000 lbs.,  $\frac{72064}{3} = 24,021$  lbs. being, as above mentioned, the permanent load a square inch will sustain.

Here  $\sqrt{\frac{18000}{4021}} = .66$ , or  $\frac{2}{3}$  of an inch square.

If the section be rectangular, the quotient must be divided by the breadth.

**Example.** If the breadth of an English wrought iron bar which is required to carry 3000 lbs. be  $2\frac{1}{2}$  inches, required its thickness. The permanent cohesive strength  $= \frac{55872}{3} = 18624$ .

Here  $\frac{3000}{18624} = .161$ , and  $.161 \div 2.5 = .064$  of an inch in thickness.

1780. The power of the resistance to compression was heretofore very much overrated. It has been well ascertained by experiment, that a force of 93,000 lbs. upon a square inch

will crush it; and that it will bear 15,300 upon a square inch without permanent alteration. The weight of cast and bar iron is as follows:—

		Weight of a cubic foot in ounces.	Weight of a cubic foot in pounds.	Weight of a cubic inch in pounds.
Cast	-	- 7207	450·5	0·260
Bar	-	- 7788	486·8	0·281

## SECT. VI.

## LEAD.

1781. Lead, the heaviest of the metals except gold and quicksilver, is found in most parts of the world. It is of a bluish white when first broken, is less ductile, elastic, and sonorous than any of the other metals, its specific gravity being from 11300 to 11479, and a cubic foot, therefore, weighing about 710 lbs. It is soluble in all acids and alkaline solutions, fusible before ignition, and easily calcined. The ore, which is easily reduced to the metallic state by fusion with charcoal, is found mineralised with sulphur, with a slight mixture of silver and antimony, in diaphanous prismatical crystals, generally hexagonal, white, yellowish, or greenish, in Somersetshire, about the Mendip Hills. About Bristol, and in Cumberland, it takes the form of a white, grey, or yellowish spar, without the least metallic appearance; in some places it is in a state of white powder or native ceruse; and in Monmouthshire it has been found native, or in a metallic state.

1782. Exposure to air and water does not produce much alteration in lead, though it quickly tarnishes and acquires a white rust, by which the internal parts are defended from corrosion. Pure water, however, does not alter it; hence the white crust on the inside of lead pipes through which water flows must probably be owing to some saline particles in the water. Lead will form an union with most other metals: one exception, however, is iron. Next to tin, it is the most fusible of metals. It is run from the furnace into moulds which form what are called *pigs*, from which it is run into sheets, pipes, &c.

1783. Sheet lead is of two sorts, *cast* and *milled*. The thicker sort of the former, or the common cast sheet lead, is manufactured by casting it on a long table (with a rising edge all round it) from 18 to 20 feet in length, which is covered with fine pressed sand beaten and smoothed down with a strike and smoother's plane. The pig lead is melted in a large vessel, near this table, and is ladled into a pan of the shape of a common triangular prism, whose length is equal to the width of a sheet, from which pan it is poured on to the table or mould. Between the surface of the sand and the *strike*, which rides upon the edges of the table, a space is left which determines the thickness of the sheet. The strike bears away the superfluous liquid lead before it has time to cool, as it moves by hand along the edges of the table before mentioned. When lead is required to be cast thin, a linen cloth is stretched on an appropriate table over a woollen one; in which case the heat of the lead, before spreading it on the cloth, must be less than will fire paper, or the cloth would be burnt. The strike must for the purpose be passed over it with considerable rapidity.

1784. In manufacturing milled lead, it is usual first to cast it into sheets from 8 to 10 feet long according to circumstances, but the width is regulated by the length of the rollers through which it is to be passed in milling; the thickness varies from 2 to 5 inches. By a mechanical action it is made to pass through rollers whose distance from each other is gradually lessened until the sheet is reduced to the required thickness. For a long time a great prejudice prevailed against milled sheet lead; but it is now generally considered that, for the prevention of leakage, milled is far superior to cast lead, wherein *pin holes*, which have naturally formed themselves in the casting, often induce the most serious consequences.

1785. The thickness of sheet lead varies from 5 to 12 pounds in weight to the superficial foot, and is used in covering large buildings, in flats or slopes, for gutters, the hips, ridges, and valleys of roofs, the lining of cisterns, &c. The subjoined table shows the weight of lead per superficial foot from one sixteenth of an inch to one inch and a half thick:—

Thickness.	Weight.	Thickness.	Weight.
One sixteenth of an inch	- 3 $\frac{3}{4}$ lbs.	One fourth of an inch	- 14 $\frac{3}{4}$ lbs.
One twelfth	- 5	One third	- 19 $\frac{3}{4}$
One tenth	- 6	One half	- 29 $\frac{1}{2}$
One eighth	- 7 $\frac{1}{2}$	Three quarters	- 44 $\frac{1}{4}$
One sixth	- 10	One inch	- 59
One fifth	- 12	One inch and a half	- 88 $\frac{1}{4}$

Lead pipes are either cast bent, or soldered. To cast them, a mould is made of brass, wherein down the middle a core of iron is loosely supported at such a distance from the mould all round, as is equal to the contemplated thickness of the pipe. When pipes are made by soldering, a core of wood is provided round which the sheet lead is rolled, and the edges are brought together and joined with *solder*, which is a mixture of two parts lead and one part tin.

1786. In cottages and inferior buildings the glazing is executed in lead prepared in the glazier's mill from what are called *canes*. These are slender rods 12 or 14 inches long, and in passing through the mill receive grooves on their upper and under edges. Into the grooves the panes or quarries of glass are inserted in common lead lights.

## SECT. VII.

### COPPER.

1787. Copper, among the first of the metals employed by the early nations of the world, is neither scarce nor difficult to work and extract from its ore. When pure it is of a pale red colour, its specific gravity 8600, and a cubic foot will weigh  $537\frac{1}{2}$  lbs.; the weight of a bar 1 foot long and 1 inch square is 3.81 lbs. These, however, vary as it is more or less hammered. Its elasticity and hardness are very considerable, and it is so malleable that it may be hammered into fine leaves. It is also very tenacious, a wire of a tenth of an inch in diameter being capable of sustaining 360 lbs.

1788. Though the ore is found in Cornwall and other parts of England, the finest in this country is the Parys mine in Anglesea, which yields principally the yellow sulphuretted ore of copper, to an annual amount of from 40,000 to 80,000 tons. This ore usually contains from one and a half to twenty-five per cent. of copper, and is partly dug in what are called *packages*, and partly blasted by gunpowder, and then broken into small pieces previous to its being roasted. This operation is performed in kilns, whose shape has a resemblance to lime-kilns, in which expedients are used for removing the ore as it is roasted, and adding fresh ore. The kilns are arched level with the upper surface of the ore, and adjoining and communicating with the kiln is the floor of a condensing chamber to receive the sulphureous vapours generated in the kiln, which fall down in the form of the finest flowers of sulphur. Several hundred tons at one time are put into the kiln, and for completing the operation six months are required. The ore is reduced to one fourth of its previous quantity by roasting, and is then washed and pressed to remove the impurities. The richer ores are then dried, and removed for smelting and refining in reverberatory furnaces, from which it is at length produced in short bars or pigs. The water which filters through the fissures is often highly impregnated with sulphate of copper, and this water is pumped up into rectangular pits about thirty feet long, twelve broad, and two deep, to mix with that in which the roasted ore has been washed; and in it are immersed pieces of iron, which, combining with the sulphuric acid, precipitate the copper in the form of a red-coloured powder slightly oxidated. The precipitate thus obtained very frequently gives above 50 per cent. of pure copper, and is even more profitable to the worker than the metal produced from the crude ore.

1789. Sheet copper was formerly much used for its lightness to cover roofs and flats; but it is almost superseded now by the use of zinc, which is much cheaper, and nearly if not quite as durable; and which, moreover, is not so liable to be corrugated by the action of the sun. Copper is reduced to sheet by being passed through large rollers, by which it can be rendered very thin. The thickness generally used is from 12 to 18 ounces to the foot superficial. Exposed to the air its lustre is soon gone; it assumes a tarnish of a dull brown colour, gradually deepening by time into one of bronze; and, lastly, it takes a green rust or calx, called *patina* by the antiquaries, which, unlike the rust of iron, does not injure and corrode the internal parts, confining itself to the surface, and rather preserving than destroying the metal. Hence, one of the most important applications of copper is in cramps for stone work, especially when they are exposed to the air. It may be here well to observe, that if water is collected from roofs for culinary purposes, copper must not be used about them, neither should any reservoirs for collecting and holding it be made of that metal.

1790. Alloyed with zinc, it forms brass for the handles of doors, shutters, locks, drawers, and the furniture generally of joinery. The usual proportion is one part of zinc to three of copper; than which it is more fusible, and is of a fine yellow colour, less liable to tarnish from the action of the air, and so malleable and ductile that it can be beat into thin leaves and drawn into very fine wire. Its specific gravity is 8370, and the weight of a cubic foot is 523 lbs. The weight of a bar 1 foot long and 1 inch square is 3.63 lbs. The extremes of the highest and lowest proportions of zinc used in it are from 12 to 25

per cent. of the brass. Even with the last, if well manufactured, it is quite malleable, although zinc by itself scarcely yields to the hammer. The appearance of brass is frequently given to other metals by washing them over with a yellow lacquer or varnish.

1791. Copper with zinc in the proportion of one tenth to one fifth of the whole forms a composition called bronze or bell-metal, used in the foundry of statues, bells, cannons, &c. When tin forms nearly one third of the alloy, a beautiful white close-grained brittle metal is formed, susceptible of a very high polish, which is used for the specula of reflecting telescopes. (See 1797.)

## SECT. VIII.

## ZINC.

1792. Zinc is found in all quarters of the globe. In Great Britain it is abundant, though therein never found in a native state. It usually contains an admixture of lead and sulphur. When purified from these, it is of a blue light colour, between lead and tin, inclining to blue. The ore, after being hand-dressed to free it from foreign matter, is roasted, by which the sulphur of the calamine and the acid of the blende are expelled. The product is then washed to separate the lighter matter, and the heavy part which remains is mixed with one eighth of its weight of charcoal. The mixture, being reduced in a mill to a powder, is placed in the pots, resembling oil jars, to be smelted. A tube passes through the bottom of each, the upper end being terminated by an open mouth near the top of the pot, and the lower end going through the floor of the furnace into water. The pots being filled with the mixture of ore and charcoal, an intense heat is applied to them by means of a furnace, by which, as the ore is reduced, the zinc is volatilized, and escapes through the tube into the water, wherein it falls in globules, which are afterwards melted and cast into moulds. Thus procured, however, it is not pure, as it almost invariably contains iron, manganese, arsenic, and copper. In order to free it from these, it is again melted and stirred up with sulphur and fat, the former whereof combines with the heterogeneous metals, leaving the zinc nearly pure, and the latter preventing the metal from being oxidated.

1793. Under rollers at a high temperature, zinc may be extended into plates of great tenacity and elasticity, or drawn into wire. These rollers are from 2 feet 8 inches to 6 feet in length, and the original thickness of the plate subjected to them is about 1 inch. A wire, one tenth of an inch diameter, will support 26 pounds. If zinc be hammered at a temperature of  $300^{\circ}$ , its malleability is much increased, and it becomes capable of much bending. Its fracture is thin, fibrous, and of a grain similar to steel. It can be drawn into wire  $\frac{1}{16}$ th of an inch in diameter, which is nearly as tenacious as that of silver. The specific gravity is somewhat below 7.0, but hammering increases it to 7.2. When heated, it enters into fusion at a heat of about  $680^{\circ}$  or  $700^{\circ}$ : at a higher temperature it evaporates; and if access of air be not permitted, it may be distilled over, by which process it is rendered purer than before, although not then perfectly pure. When heated red hot, with access of air, it takes fire, burns with an exceedingly beautiful greenish or bluish flame, and is at the same time converted into the only oxide of zinc with which we are acquainted, consisting of 23.53 parts of oxygen combined with 100 of metal.

1794. On the first introduction of zinc into this country as a material, the trades with which it was likely to interfere used every exertion to prevent its employment; and, indeed the workmen who were engaged in laying it, being chiefly tinmen, were incompetent to the task of so covering roofs as to secure them from the effects of the weather. Hence, &c. a considerable period after its first employment, great reluctance was manifested by architects in its introduction. A demand for it has, however, gradually increased of late, and the comparatively high prices of lead and copper will not entirely account for the disparity of consumption. In France, in the year 1836, the quantity consumed exceeded 12,000 tons, whilst, in the same year, in England the consumption amounted only to between 2000 and 3000 tons.

1795. Zinc, though subject to oxidize, has this peculiarity, that the oxide does not scale off as that of iron, but forms a permanent coating on the metal, impervious to the action of the atmosphere, and rendering the use of paint wholly unnecessary. Its expansion and contraction is greater than those of any other metal: thus, supposing 1.0030 to represent the expansion of it, 1.0019 is that of copper, and 1.0028 that of lead; hence, in use, proper attention must be paid to the circumstance, or a substantial and durable covering of zinc will not be obtained. The method of accomplishing this is, of course, by always allowing plenty of play in the laps.

1796. The tenacity of zinc to lead is as 16.616 to 3.328, and to copper as 16.616 to 22.570; hence a given substance of zinc is equal to five times the same substance in lead, and about three fourths of copper. The sheets in general use are 12, 14, 16, 18, and 20

ounces to the foot superficial; and as 18 thicknesses of 16 ounces to the foot are half an inch thick, the following show the thicknesses of the different weights:—

Plates or sheets of 10 ounces to the foot are 0 01736 inch thick.	
12	— 0 02063
14	— 0 02430
16	— 0 02777 = $\frac{1}{36}$ of an inch.
18	— 0 03125
20	— 0 03472

The comparative weights of the different materials used in covering buildings may be roughly stated as follows:—

A square of pantiling will weigh about	7½ cwt.
plain tiling	— 14½ cwt.
slating (a mean)	— 6½ cwt.
lead	— 5 cwt.
zinc (15 oz.)	— 1 cwt.

And as the timbers employed, of course, are less in dimension as the weight diminishes, it follows that a less quantity of timber is requisite when zinc can be employed.

1797. It is a good material for water-cisterns and baths, rain-water pipes,—in short, for almost all purposes where lead has been hitherto employed; and latterly a method has been invented, by which it is formed into sash-bar for skylights and ornamental sashes; for which purposes, strength excepted, it is superior to iron, as not being liable to rust, and loosen the putty and glass. It is, in every respect, equal to copper, and not more than one third the cost of it. The discovery of the electro-process has now introduced the application of zinc to cast and wrought iron, so as to prevent its oxydation or rust; and, we believe, that the tenacity of the iron is not altered by it, whilst the adhesion of the coating to the iron thereunder is perfect. This process has been carried into use by Messrs. Elkington and Co., and has by them been also applied to copper.

## SECT. IX.

### SLATES.

1798. Slate is a species of argillaceous stone, and is an abundant and most useful mineral. The slate district in England is of considerable extent. This material is so soft, that the human nail will slightly scratch it, and is of a bright lamellated texture. Its constituent parts are argyll, earth, silex, magnesia, lime, and iron; of the two first and the last in considerable proportion. The building slate is the *schistus tegularis*.

1799. The slates used about London are brought chiefly from Bangor, in Caernarvonshire; but the most esteemed is a pale blue-green slate, brought from Kendal, in Westmorland, and called Westmorland slates. Those from Scotland are not in much repute. Slate quarries usually lie near the surface; and, independent of the splitting grain, along which they can be cleft exceedingly thin, they are mostly divided into *stacks*, by breakings, cracks, and fissures. Slate is separated from its bed, like other stones, by means of gunpowder, and the mass is then divided into scantlings by wedges, and, if necessary, sawn to its respective sizes by machinery. The blue, green, purple, and darker kinds are most susceptible of thin cleavage, the lighter-coloured slates being coarser. The instruments used in quarrying and splitting slates are slate-knives, axes, bars, and wedges. In fixing them on roofs the *zax* is used. This is an instrument made of tempered iron, about 16 in. long and 2 in. wide, like a large knife bent a little at one end, with a wooden handle at the other, and having a projecting piece of iron on its back, drawn to a sharp point, to make holes in the slates for the nails, the other side being used to chip and cut the slates to their required size, as when brought from the quarry they are not sufficiently square and cleaned for the slater's use.

1800. A fine sound texture is the most desirable among the properties of a slate; for the expense of slating being greatly increased by the boarding whereon it is placed, if the slate absorbs and retains much moisture, the boarding will soon become rotten. But a good slate is very durable. Its goodness may be judged of by striking it as you would a piece of pottery, wherefrom a sonorous, clear, bell-like sound is a sign of excellence; but many pieces of the slate should be tried before a conclusion can be arrived at. It is thought to be a good sign, if, in hewing, it shatters before the edge of the *zax*. The colour, also, is some guide, the light blue sort imbibing and retaining moisture in a far less degree than the deep black-blue sort. The feel of a slate is some indication of its goodness: a good one has a hard and rough feel, whilst an open absorbent slate feels smooth and greasy. The best method, however, of testing the quality of slates is by the use of water, in two ways. The first is, to set the pieces to be judged of edgewise in a tub of water, the water reaching above half way up the height of the pieces: if they draw water, and become wet to the top in six or eight hours' time, they are spongy and bad; and as the water reaches less up them, so are the pieces better. The other method is, to weigh the pieces of slate, and note their weights. Let them then remain for twelve hours in water, and take them

out, wiping them dry. Those that on re-weighing are much heavier than they were previous to their immersion should be rejected. Where the character of a slate quarry is not previously known, experiments of these sorts should never be omitted.

1801. The following comparison of the advantages of slates over tiles is given by the late Bishop of Llandaff. That sort of slate, other circumstances being the same, is esteemed the best which imbibes the least water; for the water imbibed not only increases the weight of the covering, but in frosty weather, being converted into ice, swells and shivers the slate. This effect of frost is very sensible in tiled houses, but is scarcely felt in those which are slated, for good slates imbibe but little water; though tiles, when well glazed, are rendered in some measure similar to slate in this respect. The bishop took a piece of Westmorland slate and a piece of common tile, and weighed each of them carefully. The surface of each was about thirty square inches. Both the pieces were immersed in water about ten minutes, then taken out, and weighed as soon as they had ceased to drip. The tile had imbibed about a seventh part of its weight of water, and the slate had not imbibed a two-hundredth part of its weight; indeed, the wetting of the slate was merely superficial. He placed both the wet pieces before the fire; in a quarter of an hour the slate was perfectly dry, and of the same weight as before it was put in the water; but the tile had lost only about twelve grains it had imbibed, which was, as near as could be expected, the very same quantity that had been spread over its surface; for it was the quantity which had been imbibed by the slate, the surface of which was equal to that of the tile. The tile was left to dry in a room heated to sixty degrees, and it did not lose all the water it had imbibed in less than six days. We here subjoin a succinct account of the different sorts of slates brought to the London market, and enumerate them in the order of their goodness and value.

1802. *Westmorland slates.* These are from 3 ft. 6 in. to 1 ft. in length, and from 2 ft. 6 in. to 1 ft. in breadth. They should be nailed with not less than sixpenny and eightpenny copper or zinc nails (iron nails should never be used); and a ton in weight of them will cover about two squares and a quarter. We may here observe, that the weight of the coarsest Westmorland slates is to that of common tiling as 36 to 54.

1803. *Welsh rags* are next in goodness, and are nearly of the same sizes as those last mentioned; but a ton of these will cover only one square and three quarters.

1804. *Imperials* are from 2 ft. 6 in. to 1 ft. in length, and about 2 ft. wide.

1805. *Duchesses* run about 2 ft. long and 1 ft. wide, and are nailed usually so as to show a ten and a half inch gauge.

1806. *Countesses*, of which a ton will cover about three squares, run about 1 ft. 8 in. in length by about 10 in. in width.

1807. *Ladies* are generally about 15 in. long, and about 8 in. wide. These are sold by the thousand of twelve hundred, which quantity will cover about four squares.

1808. There are still other sorts of slates which have been used in and about London, as the *Dennyhole*, &c. The *Tavistock slates* were at one period in considerable demand. They are sold by the thousand of ten hundred, which quantity covers about three squares and forty feet. The smallest slates in use are called *Doubles*: they run about 13 in. in length by 6 in. in width. The bond or lap of a slate is the distance between the nail of the under slate and the lower end of the upper slate, and, as in tiling, the gauge in slating is the visible depth of the slate.

1809. Several years ago, a patent was obtained for slating roofs without boarding or battens. In this the slates were all reduced to widths equal to the distance between centre and centre of the rafters. On the backs of these last they are screwed by two or three strong inch and half screws at each of their ends. Over the junctions of the slates, on the backs of the rafters, fillets of slates about two and a half or three inches wide, bedded in putty, are screwed down, to prevent the entrance of rain. The handsome regular appearance of this sort of slating gained it at first much celebrity; but it was soon abandoned, on account of the disorder it is liable to sustain from the slightest partial settlement of the building, not less than from the constant dislodgement of the putty, upon which greatly depended its being impervious to rain.

1810. Slating is sometimes laid lozengewise; but it is much less durable than when laid in the common method.

## SECT. X.

### BRICKS AND TILES.

1811. A brick is a factitious sort of stone, manufactured from argillaceous or clayey earth, well tempered and squeezed into a mould. When so formed, bricks are stacked to dry in the sun, and finally burnt to a proper degree of hardness in a clamp or kiln. The use of bricks is of the highest antiquity. They are frequently mentioned in the historical

books of the Old Testament ; but whether they were merely sun-dried or burnt in a kiln seems uncertain. We are inclined to doubt the burning of them at a very remote period. It will immediately occur to the reader that the making of bricks was one of the tasks imposed upon the Israelites during their servitude in Egypt. Though the oldest remains in Egypt are of stone, Pococke describes a pyramid of unburnt bricks, which are composed of a black sandy earth, intermixed with pebbles and shells, the sediment deposited by the overflowing of the Nile. This species of bricks is still common in Egypt and many other parts of the East. By the ancient Greeks and Romans, both burnt and unburnt bricks were used ; the method of making the latter whereof is thus described by Vitruvius, in the third chapter of his second book : “ I shall first,” says that author, “ treat of bricks, and the earth of which they ought to be made. Gravelly, pebbly, and sandy clay are unfit for that purpose ; for if made of either of these sorts of earth, they are not only too ponderous, but walls built of them, when exposed to the rain, moulder away, and are soon decomposed ; and the straw, also, with which they are mixed, will not sufficiently bind the earth together, because of its rough quality. They should be made of earth, of a red or white chalky, or a strong sandy nature. These sorts of earth are ductile and cohesive, and not being heavy, bricks made of them are more easily handled in carrying up the work. The proper seasons for brick-making are the spring and autumn, because they then dry more equably. Those made in the summer solstice are defective, because the heat of the sun soon imparts to their external surfaces an appearance of sufficient dryness, whilst the internal parts of them are in a very different state ; hence, when thoroughly dry, they shrink and break those parts which first dried ; and thus broken, their strength is gone. Those are best which have been made at least two years ; for in a period less than that, they will not dry thoroughly. When plastering is laid and set hard on bricks which are not perfectly dry, the bricks, which will naturally shrink, and consequently occupy a less space than the plastering, will thus leave the latter to stand of itself. From its being extremely thin, and not capable of supporting itself, it soon breaks to pieces ; and in its failure, involves sometimes even that of the wall. It is not, therefore, without reason that the inhabitants of Utica allow no bricks to be used in their buildings which are not at least five years old, and also approved by a magistrate.

1812. “ There are three sorts of bricks : the first is that which the Greeks call *Didoron* (*διδωρον*), being the sort we use ; that is one foot long and half a foot wide. The other two sorts are used in Grecian buildings ; one is called *Pentadoron*, the other *Tetradoron*. By the word *doron*, the Greeks mean a palm, because the word *δωρον* signifies a gift which can be borne in the palm of the hand. That sort, therefore, which is five palms each way, is called *Pentadoron* ; that of four palms, *Tetradoron*. The former of these two sorts is used in public buildings, the latter in private ones. Each sort has half bricks made to suit it, so that when a wall is executed, the course on one of the faces of the wall shows sides of whole bricks, the other face of half bricks ; and being worked to the line on each face, the bricks on each bed bond alternately over the course below.” Vitruvius concludes the chapter with the mention of the bricks made at Calentum in Spain, at Marseilles in France, and Pitane in Asia, which are specifically lighter than water.

1813. It is to be regretted that plastering with cement, a practice which is more to the interest of the brickmaker and bricklayer than to the consumer, has become so prevalent in this country. These tradesmen thus get rid of their worst bricks, which are hidden by a coat of plaster ; the building soon decaying when the heart of the wall is bad. Colour seems to be the objectionable quality about this material, the commonplace architect forgetting that form is much more essential to beauty than colour. In the times of Jones and Wren, red brick was beautifully wrought into architectural forms, of which a few examples still remain in the metropolis ; and by Palladio, bricks were used for columns without smearing them over with plaster.

1814. In England, the best earth for making bricks is a clayey loam, neither abounding with too much sand, which renders them brittle, nor with too large a portion of argillaceous matter, which causes them to shrink and crack in drying. It should be dug at the least a year before it is wrought, that by exposure to the atmosphere it may part with all extraneous matter which it possessed when first dug. The general practice is, however, to dig it in the autumn, and allow it to remain through the winter to mellow and pulverize, by which the operation of tempering is greatly facilitated. Upon this operation the quality of the brick mainly depends, and great attention should be bestowed upon performing this part of the process in a proper manner. This branch of the manufacture was formerly executed by throwing the clay into shallow pits, and subjecting it to be trodden by men and oxen ; a method which has been advantageously superseded by a clay or pug-mill, with a horse track.

1815. As soon as the clay has been thoroughly tempered by one of the methods above named, it is taken to the moulder's bench, where it is cut by the moulder's assistant, generally a woman or a lad, into pieces rather larger than the mould, which are passed on to the moulder, who throws it with some force into the mould, which has been previously

dipped in sand. He presses it down, so that it may fill the whole of the cavity, striking off the superfluous clay with a flat wooden rule. The newly-formed brick is then turned out of the mould on to a thin board, somewhat larger than a brick, and it is removed by a boy to a latticed wheelbarrow, and conveyed, covered with fine dry sand, to the *hack*. A handy moulder, working fifteen hours, will mould 5000 bricks. In the hacks, which are eight courses in height, the bricks are arranged diagonally above each other, with a passage between each for the circulation of air round them. The time required for drying in the hacks will, of course, depend on the fineness of the weather; it is but a few days if the season be propitious; and they are then turned and reset wider apart, after which, in about six or eight days, they are ready for the clamp or kiln. If the weather be rainy, the bricks in the hack must be covered with wheat or rye straw; and as they ought to be thoroughly dry before removing to the clamp or kiln, a few are generally selected from different parts, and broken, to ascertain if the operation of drying has been well performed. The moisture arising from bricks when burning is very injurious to their soundness.

1816. In the brickfields about London, bricks are mostly burnt in what are called *clamps*. These are generally oblong in form, and their foundations are made with the driest of the bricks from the hacks, or with common unglazed bricks, called *place bricks*. The bricks for burning are then arranged, tier over tier, to the height assigned to the clamp, according to the quantity to be burnt, and a layer of breeze, or cinders, two or three inches deep, is placed between each course of bricks, and the whole, when built up, covered with a thick stratum of breeze. On the western face of the clamp a vertical fireplace is formed, about 3 feet in height, from which flues are driven out by arching the bricks over, so as to leave a space about one brick wide. The flues run in a straight direction through the clamp, and are filled with a mixture of coals, breeze, and wood, so that the fire may pass through the clamp, and the bricks may be burnt quickly, the flues should not be more than 4 feet apart, and the distance between the flues should be nearer than 5 feet to each other, and the clamp is allowed to burn slowly. It is possible, if required, to burn a clamp in a period of from 20 to 30 days, according to the dryness of the weather. The quantity of clay necessary to make 1000 bricks will be somewhere about 54 cubic feet, which allows about 5 feet for shrinkage in drying and burning; for 1000×34 in.×24 in.×4 in.=49 2 3/4 4'''.

The cost of making 1000 bricks, in the neighbourhood of London, is nearly as follows :—

Digging, wheeling, carting, &c.	-	-	-	-	-	0	1	6
Moulding, stacking, &c.	-	-	-	-	-	0	11	6
Sand, one-sixth of 2s.	-	-	-	-	-	0	0	4
Straw for backs	-	-	-	-	-	0	0	9
Barrows, moulds, planks, &c.	-	-	-	-	-	0	0	6
Fuel 9 cwt. per 1000	-	-	-	-	-	0	10	6
						£	1	5
							1	

1817. The kilns which are used for burning bricks are usually 13 feet long, by 10 feet 6 inches in width, and 10 feet in height. The walls are one brick and a half thick, and incline upwards as they rise. A kiln is generally built to contain 20,000 bricks at each burning. The fireplace consists of three arches, which have holes at top for discharging heat to the bricks. These are placed on a lattice-like floor, and first undergo a gentle action of the fire for two or three days, in order to dry them thoroughly. As the bricks thus become ready for burning, the mouth of the fireplace is dammed up with brushwood, and a fire is kindled, which consists of 1,000 of brick laid end to each other, and closed with wet brick, thus forming a sort of a sufficient room, to introduce a faggot. The kiln is then supplied with brushwood, straw, &c., and the fire is kindled and kept up until the arches assume a white appearance, and the smoke begins to issue through the top of the kiln. The fire is then slackened, and the kiln gradually cooled. This process of alternately raising and slackening the heat of the kiln is repeated till the bricks are thoroughly burnt, which is usually accomplished in about eight and forty hours.

1818. The practice of steeping bricks in water after they have been burnt, and then again burning them, has been found to have the effect of considerably improving their quality.

1819. There are several sorts of bricks, which may be classed as follows: malms or marl stocks, stocks, place bricks, fire bricks, paving bricks, compass bricks, concave or hollow bricks, and Dutch or Flemish bricks. There are still other varieties; but from their being now but little used, we shall pass them over.

1820. The marl for the marl stock, which is of a bright yellowish uniform colour and texture, is not always to be had, especially in the London districts; in consequence of which, several years ago, it was discovered that chalk mixed in certain portions with loam, and treated in the usual manner, proved an excellent substitute for it. It not only was found to improve the colour, but to impart soundness to the brick; and the practice is now generally adopted about London. At Emsworth, in Hampshire, and also at Southampton, ooze, or sludge, from the sea-shore, containing much saline matter, is used for a similar purpose: these bricks, however, have not the rich brimstone colour of the London malm stock, nor the regular stone-coloured hue of the Ipswich bricks.

1821. The finest marl stocks, which are technically called *firsts*, or *cutters*, are principally used for arches of doorways and windows, quoins, &c., for which purposes they are rubbed and cut to their proper dimensions and form. There is also a red cutting brick, whose texture is similar to the malm cutter, which must not be confounded with the red stock. The next best, which are chiefly used for principal fronts, are called *seconds*: they are not quite so uniform in colour, nor so bright as the last, but are, nevertheless, a handsome and durable brick.

1822. *Stocks* are red and grey, both sorts being equal in texture. The red sort are burnt

in kilns. The grey stocks are less uniform in their colour than seconds, and are of rather an inferior quality. They are used for common fronts, and walls.

1823. *Place bricks*, or *peckings*, sometimes also called *sandel*, or *samel bricks*, are those which, having been outermost or furthest from the fire in the clamp, or kiln, have not received sufficient heat to burn them thoroughly. They are, consequently, soft, uneven in texture, and of a red colour. These should never be used in a building where durability is required.

1824. *Burrs* and *clinkers* are such bricks as have been violently burnt, or masses of several bricks run together in the clamp or kiln.

1825. The red bricks derive their colour from the nature of the soil whereof they are composed, which is generally very pure. The best of them are used for cutting-bricks, and are called red rubbers. In old buildings they are frequently found set in putty, and often carved into ornaments over arches, windows, doorways, &c.

1826. *Fire bricks*, so called from their capability of resisting the most violent action of the fire, are of a dark red colour, and of very close texture; they are made about 9 inches long, 4½ inches broad, and 1½ inches thick. The loam of which they are made is yellow, harsh to the touch, and contains a considerable portion of sand. Their quality renders them highly serviceable in furnaces and ovens. The greatest part of those used about London were formerly brought from Hedgerly, a village near Windsor, whence they obtained the name of Windsor bricks. This sort of brick is made also in various parts of Wales, whence they are called *Welsh lumps*.

1827. *Paving bricks* are for the purpose which their name implies, and their dimensions are the same as those of the foregoing sort.

1828. *Compass bricks* are circular on the plan, and are chiefly employed for *steining*, or walling round wells.

1829. *Concave* or *hollow bricks* are made like common bricks, but hollowed on one side in the direction of their length, and are adapted to the construction of drains and water-courses.

1830. *Dutch clinkers* and *Flemish bricks* vary little in quality; they are exceedingly hard, and are used for the paving of stables, yards, &c., though they are by some objected to, as being too hot for the horses' feet. The former are 6 inches long, 3 inches broad, and 1 inch thick, and are often laid on edge in various fanciful forms, as the herring-bone, &c.

1831. By the 17th Geo. III. cap. 42. all bricks made for sale shall, when burnt, be not less than 8½ inches long, 2½ inches thick, and 4 inches wide. The very limitation is enough to prove the total disregard of the ministers of this country, at all times, to the advancement of the arts. It is scarcely possible to be believed that the statute still continues in force.

1832. Bricks laid in the summer season should be well saturated with water previous to laying; and if the work be left for a day only, the walls should be as carefully covered up as in the winter, for in hot weather the mortar sets too rapidly, and hence the necessary cohesion is destroyed; an evil much aggravated by the dust constantly hanging about the bricks, more especially at that season of the year.

1833. Three hundred and thirty well-burnt bricks may be generally taken as weighing 20 cwt., so that a cubic foot weighs about 125 lbs; and it is found by experiment, that to crush a mass of solid brickwork whose section is 1 foot square, a weight of 300,000 lbs. *avardupois* must be applied.

1834. *TILES*, which in their constituent parts partake much of the nature of bricks, are plates of clay baked in a kiln, and used instead of slates, or other covering of the roofs of houses. The clay whereof tiles are formed will always make good bricks, though the converse does not hold, from the toughness required on account of their being so much thinner than bricks. The common kinds are made of a blue clay, found in many parts about London, though mostly deeper seated than brick earth. The best season for digging it is in September and October, and it should then lie exposed during the winter. It may, however, be turned up in January, and worked in February; and, as in brick, so in tile-making, the more care bestowed on beating and tempering the clay, the better will be the tiles. Tiles are burnt in a kiln constructed on the same principles as the brick-kiln, but with the addition of a cone, having an opening at top round the chamber of the kiln. They require much care in burning. If the fire be too slack, they will not burn sufficiently hard; and if too violent, they glaze, and suffer in form.

1835. *Plain* or *crown tiles* are such as have a rectangular form and plane surface. They should be 10½ inches long, 6½ inches broad, and ½ of an inch thick, according to the statute, and they will weigh each from 2 to 2½ lbs. They are manufactured with two holes in them, through which, by means of oak pins, they hang upon the laths. In using all coverings of this species, one tile laps over another, or is placed over the upper part of the one immediately below; that part of the tile which then appears uncovered is called the *gauge* of the tiling. If, in plain tiling, the gauge be 6½ inches, about 740 tiles will cover one square, or 100 feet superficial.

1836. *Ridge roof and hip tiles* are formed cylindrically, to cover the ridges of houses. They should be 13 inches long, and girt about 16 inches on the outside. Weight about 5 lbs.

1837. *Gutter tiles* are about the same weight and dimensions as ridge tiles, but are for the valleys of a roof. They are now rarely used, their place having been long since supplied by lead.

1838. *Pan or Flemish tiles* have a rectangular outline, with a surface both convex and concave, thus . They have no holes for pins, as plain tiles have, but are hung on to the laths by a knot of their own earth on their underside, nearest the ridge, formed when making. They are often glazed, should be  $14\frac{1}{2}$  inches long and  $10\frac{1}{2}$  inches broad, and weigh from 5 to  $5\frac{1}{4}$  lbs. They are usually laid at a 10 inch gauge, and a square at that gauge will take 170 pan tiles.

1839. The largest sort of paving tiles are 1 foot square and  $1\frac{1}{2}$  inch thick. The next size, called 10 inch tiles, are, in fact, only 9 inches square and  $1\frac{1}{2}$  inch thick.

## SECT. XI.

## LIME, SAND, WATER, AND CEMENT.

1840. Lime has not been found in a native state; it is always united to an acid, as to the carbonic in chalk. By subjecting chalk or limestone to a red heat it is freed from the acid, and the lime is left in a state of purity, and is then called caustic or quicklime, which dissolves in 680 times its weight of water. It is not our intention here to enter into any account of either of the theories relative to the formation of lime, facts being of more importance to the architect in its employment than the refined fancies of the scientific chemist. The calcareous minerals are mostly distinguished by their effervescing with acid and dissolving in an acid, as also by their being easily scratched or cut with a knife. In respect of the lime obtained from chalk, Dr. Higgins (in his work on calcareous cements, Lond. 1780) says, "It should be observed, that the difference between chalk lime and the lime obtained from the various limestones, chiefly consists in the greater retention or expulsion of the carbonic acid gas contained in them."

1841. An account of the stone from which lime may be obtained in the different counties of England would unnecessarily extend this article; we shall, therefore, after observing that the use of marble for burning to lime would be too expensive, state the varieties of limestone as, 1. the compact; 2. the foliated; 3. the fibrous; and, 4. the peastone. The compact limestones are of various colours, in hues inclining to grey, yellow, blue, red, and green, and to a smoky sort of colour besides. It is usually found massive, often compounded with extraneous fossils, particularly shells. Its internal appearance is dull, the texture is compact, the fracture small, fine, and splintery; fragments indeterminate angular, more or less sharp-edged; semihard, sometimes soft, brittle, and easily frangible. Specific gravity varies from 2500 to 2700, and it is composed of lime, carbonic acid, and water, mostly with a portion of argyll and oxide of iron, and sometimes of inflammable matter.

1842. The foliated limestones are such as calcareous spar, statuary marble, &c.; the fibrous limestones, such as satin spar; and the pea stone, another species of spar. It may be remarked, that the various sorts of marble, chalk, and limestone may be divided into those which are nearly pure carbonate of lime, and those containing in addition from one twentieth to one twelfth of clay and oxide of iron. "Though the best limestones are not such as contain the greatest quantity of clay, yet," observes Mr. Smeaton, "none have proved good for water building, but what, on examination of the stone, contained clay; and though, he continues, "I am very far from laying down this as an absolute criterion, yet I have never found any limestone containing clay in any considerable quantity, but what was good for water works, the proportion of clayey matter, being burnt, acting strongly as a cement; and limes of this kind all agree in one more property, that of being of a dead frosted surface on breaking, without much appearance of shining particles."

1843. Among the strongest limes, and such as will set under water, those most in use in the metropolis and its neighbourhood are procured from Dorking, Mersham, and the vicinity of Guilford. The most celebrated in the West of England is the blue lias of Somersetshire, and in the north that about the county of Sunderland, whereof very large quantities are exported to Scotland. The Dorking and other limes of that part are burnt from a chalk formation so extremely hard that it is quarried even for the purposes of masonry. Those of Mersham particularly are obtained from an indurated chalk marl (clay and chalk) which is so hard that it partakes of the nature of stone. The known property of the lias formation for setting under water renders it an invaluable material in the hands of the architect. In the neighbourhood of Bath it is called Bath brown lime,

and when prepared for cementing with metallic cement, is said to be *wind slacked*; that is, after burning, it is placed in roofed sheds open at the sides, and the atmosphere is thus introduced to act upon it. The colour of the *lias*, previous to burning, is blue; after it has passed the kiln, it is of a rich brown colour. No accurate analysis of this has come to our knowledge; but we have understood that specimens have been analysed, containing as much as 90 per cent. of carbonate of lime, the residuum probably consisting of alumen and iron. The magnesian limestone of Sunderland lies north-west of the red sandstone. In the vicinity of South Shields, in the county of Durham, the formation becomes extensive, and is to be traced to the Tees below Winston Bridge. The Whithy quarry near Calleroats has been described in the 4th volume of the *Geological Transactions*. The Sunderland limestone is of a bronze colour, and from containing inflammable matter, does not require so much fuel to convert it into lime.

1844. Before limestone is burnt it seems to possess no external character by which a distinction can be made between the simple and the argillo-ferruginous limestones; whatever the colour of the former, they become white when burnt, whilst the latter partake more or less of a slight ochrey tint. Brown lime is the most esteemed for all sorts of cements, whilst for common purposes, the white sorts, which are more abundant, are sufficiently useful. In England, the limestones in colour generally incline to a red or blue, and those which are found firm, weighty, and uniform in texture are to be preferred. Masses broken from large rocks and beds on the sides of hills, and those when newest taken and deepest dug, are most to be valued.

1845. The process of analysing limestones is so eminently useful to all concerned in building, that we cannot refrain from transcribing the method used by Smeaton in his own words. "I took about the quantity of five pennyweights (or a guinea's weight) of the limestone to be tried, bruised to a coarse powder, upon which I poured common aquafortis, but not so much at a time as to occasion the effervescence to overtop the glass vessel in which the limestone was put, and added fresh aquafortis after the effervescence of the former quantity had ceased, till no further ebullition appeared by any addition of the acid. This done, and the whole being left to settle, the liquor will generally acquire a tinge of some transparent colour; and if from the solution little or no sediment drops, it may be accounted a pure limestone (which is generally the case with white chalk and several others), as containing no uncalcareous matter in its composition. When this is well settled, pour off the water, and repeatedly add water in the same way, stirring it, and letting it settle till it becomes tasteless. After this, let the mud be well stirred into the water, and without giving it time to settle, pour off the muddy water into another vessel, and if there is any sand or gritty matter left behind (as will frequently be the case), this collected by itself will ascertain the quantity and species of sabulous matter that entered into the texture of the limestone. Letting, now, the muddy liquor settle, and pouring off the water till no more can be got without an admixture of mud, leave the rest to dry, which, when of the consistence of clay, or paste, is to be made into a ball, and dried for further examination."

1846. The loss of limestone by burning is about four ninths of its weight, shrinking, however, but little. When completely burnt, it falls freely, in slaking, into powder, and then occupies about double its previous bulk.

1847. There are many sorts of kilns for burning limestone, varying in form with the fuel employed, and the combination of the process itself with some other, such, for instance, as making coke, and sometimes bricks. The limestone, however, is generally burnt in kilns whose plans are circular and section resembling an inverted truncated cone; of late more frequently made spheroidal. The heat is in either case obtained from a fireplace under the limestone, which rests on bars, that can, when the kiln is a perpetual one, egg-formed, or a draw kiln, be removed, to let out the lime as it is burnt, whose deficiency, on extraction, is supplied by fresh stone at the top of the kiln. *Sod kilns* are sometimes used for lime burning. These are formed by excavating the earth in a conical form, and then building up the sides as the earth may require. In using these, the limestone is laid in with alternate layers of fuel to the top of the kiln, and the top being covered with sods, so as to prevent the heat from escaping, the fire is lighted, and the process effected. The lime is not removed till it is thoroughly cool. This mode is a tedious operation, and, because of the quantity of fuel consumed, far from economical. In the common lime-kiln, the fire is never suffered to go down, but as the well-burnt lime is removed, fresh lime is supplied. There is a species of kiln called a flame-kiln, in which the calcination is effected with peat. In this kiln the process of burning bricks is carried on at the same time.

1848. Lime burners have made the important observation, that the quantity of stone calcined and the quantity of fuel expended depend on the quality of the fuel. Hence the kiln is constructed with reference to the fuel, rather than to the nature of the stone to be calcined. Limestone, taking an average time, requires burning about sixty hours to reduce it to lime, when the heat is strong and well regulated: but of course no general rule can be laid down, as different species will require different periods of time. The principal object

to be accomplished, is the expulsion of the carbonic acid gas which enters into its composition.

1849. That lime is generally most esteemed which heats most in slaking, and slakes the quickest, falling into a fine powder. If there be among it coarse unslakeable lumps called *core*, that will not pass through the screen, either the stone has not been sufficiently burnt, or it originally contained extraneous matter; which not only indicates defect in quality, but that it will be, as they more or less abound, more costly in use.

1850. From the experiments of Mr. Smeaton and of Dr. Higgins, it is sufficiently proved that, when chalk or stone lime is equally fresh when used, the cementitious properties of both are nearly, if not quite, equal; but from the circumstance of quicklime absorbing carbonic acid more or less in proportion as its texture is solid or spongy, so it gradually parts with its cementing nature, becoming at length altogether unfit for the purposes of mortar. Thus, though each of the sorts may be equally good, if properly burnt and quite fresh from the kiln, yet from the chalk lime so much more easily and rapidly taking in the carbonic acid than stone lime does, it is not so fit for general use; and, indeed, now the metropolis is so well supplied with the harder chalk and stone limes, there is no excuse for its use, and it should in sound building be altogether banished.

1851. The following table, from Smeaton, contains a list of the limestones he examined on the occasion of building the Eddystone Lighthouse.

Species of Stone.	Proportion of Clay.	Colour of the Clay.	Reduction of Weight by burning.	Colour of Brick made of such Clay.
Aberthaw, on the coast of Glamorganshire - - -	$\frac{3}{23}$	Lead colour	4 to 3	Grey stock brick
Watchet, small sea-port in Somersetshire - - -	$\frac{3}{25}$	Do.	4 to 3	{ Light colour, reddish hue.
Barrow, Leicestershire - - -	$\frac{3}{14}$	Do.	3 to 2	Grey stock brick.
Long Bennington, a village in Lincolnshire - - -	$\frac{3}{22}$	Do.	- -	Dirty blue.
Sussex Church, near Lewes in Sussex - - -	$\frac{3}{16}$	Ash colour	3 to 2	Ash colour.
Dorking in Surrey - - -	$\frac{1}{17}$	Do.		
Berryton grey lime, near Petersfield, Hants - - -	$\frac{1}{12}$	Do.		
Guilford, Surrey - - -	$\frac{2}{19}$	Do.		
Sutton, Lancashire - - -	$\frac{3}{16}$	Brown		

1852. In forming mortar from the lime, it must, when slaked, be passed through a sieve leaving only a fine powder, an operation usually performed with a quarter inch wire screen set at a considerable inclination to the horizon, against which the lime is thrown with a shovel after slaking. That which passes through is fit for use; the core falling on that side of the screen against which the lime is thrown, being entirely rejected for the purpose in question, though it is an excellent material for filling in the sides of foundations under wood floors where they would otherwise be next the earth, and the like. The sifted or screened lime is next to be added to the sand, whose quantity will vary as the quality of the lime, of which we shall presently speak. In making mortar, there is no point so important as respects the manufacture itself, as the well tempering and beating up the lime with the sand after the water is added to them. In proportion, too, as this is effectually done, will a small proportion of lime suffice to make a good mortar. The best mode of tempering mortar is by means of a pug-mill with a horse-track similar to the clay-mills used for making bricks. But if such cannot be had, the mortar should be turned over repeatedly, and beaten with wooden beaters, until it be thoroughly mixed. That this process should be carefully performed, will appear of the more importance when it is considered that it thereby admits a greater proportion of sand, which is not only a cheaper material, but the presence of it renders a less quantity of water necessary, and the mortar will consequently set sooner: the work, too, will settle less; for as lime will shrink in drying, while the sand mixed with it continues to occupy the same bulk, it follows that the thickness of the mortar beds will be less variable. It may be taken, indeed, as an axiom, that no more lime is necessary than will surround the particles of sand.

1853. In most of the public works executed in Great Britain of late years, the proportion of lime to sand is as 1 to 3; and when the former is made from good limestone, the sand is by no means too much in proportion. Dr. Higgins, in his experiments, has gone so far as to recommend 7 parts of sand to 1 of lime, which, for mortar, is perhaps carrying the point to the extreme.

1854. Various additions are made to mortar, in order to increase its hardness and

tenacity; such as coal and wood ashes, forge scales, roasted iron ore, puzzuolana, and the like. The *cendre de Tournay* is used in the low countries. This is an article procured from the lime-kilns bordering the Scheldt. The lime of this district contains a considerable portion of clay mixed with iron; and the pit-coal with which it is burnt contains a large quantity of an argillaceous schist, impregnated with iron. After the lime is taken out of the kilns, there remains the cendre, about one fourth of which consists of burnt lime-dust, and three fourths of coal-ashes. This material is sprinkled with water to slack the lime, and well mixed together, and put into a proper vessel and covered over with wet earth. In this state it is kept for a considerable time; and when taken out, and strongly beaten up for half an hour with an iron pestle in a wooden mortar or trough, it is reduced to a soft pasty consistence; it is then spread out for several days in a shady place, and the operation of beating repeated: the oftener this is done the better, except it should become unmanageable from being too much dried. In a few minutes, this cement, when applied to brick or stone, adheres so firmly that water may be immediately poured over it; and if kept dry twenty-four hours, it afterwards receives no injury even from the most violent action of a flowing stream.

1855. In London, a blue mortar is used for covering parts of buildings much exposed to the weather; and if prepared with similar labour and attention, it might, in a great degree, possess the valuable properties of the mortar of the Scheldt, just mentioned.

1856. Common ashes mortar is made by mixing two bushels of newly slacked lime and three bushels of wood ashes, which, when cold, must be well beaten, in which state it is usually kept for a considerable time, and indeed it improves by keeping if beaten two or three times previous to using it. This mixture is superior to terras mortar in resisting the alternate effects of dryness and moisture, but not comparable with it under water.

1857. Mr. Smeaton discovered, by a course of experiments, that the scales (grey oxide of iron) that fly off under the forge hammer from red hot iron, pulverised, sifted, and mixed with lime, form an admirable cement, equal to puzzuolano. He found, in pursuing his experiments, that roasted iron ore produced an effective water cement, by using a greater proportion of it than either terras or puzzuolano. Equal quantities of iron scales and argillaceous lime, with half the quantity of each of these of sand, produced a cement in every respect equal to terras mortar. If pure carbonate of lime be used, equal parts of each of the ingredients ought to be incorporated. We do not think it necessary here to give any account either of Lorient's cement, nor that proposed by Semple: neither are to be depended on: indeed the first, as a water cement, is of inferior utility, and very little better than common mortar dried before the admission of water upon it.

1858. Sand should by all means, if possible, be procured from a running clear stream, in preference to that obtained from pits. It is cleaner, and not so connected with clayey or muddy particles. About the metropolis it is the practice to use (and an admirable material it is) the sand of the Thames procured from above London Bridge. This sand has acquired a deserved reputation among the architects and builders of the capital. It contains, however, a vast portion of heterogeneous matter, such as calcareous fossil, quartzose, and flint sands, particles of coal alluvium, and much iron. The sharp drift sand of the Thames should therefore, before mixing with the lime, be well screened and washed.

1859. If pit sand only can be procured, it should be repeatedly washed, to free it from the earthy and clayey particles it contains, until it becomes bright in colour, and feels gritty under the fingers. When the architect is obliged to use sea sand, it must be well washed in fresh water until the salt is entirely removed; otherwise the cement for which it is used will never dry.

1860. *Grout, or liquid mortar*, is nothing more than common mortar mixed with a sufficient quantity of water to make it fluid enough to penetrate the interstices and irregularities of the interior of brick walls, which common mortar will not reach. The mortar whereof it is made will bear 4 of sand to 1 of lime, but it should be thoroughly beat. It may be kept a little longer, whereby its quick setting will be facilitated.

1861. *Water*. Dr. Higgins recommends the use of lime water for the composition of mortar. This, in practice, would be impossible. The water used, however, for the incorporation of the lime with the sand should be soft and pure. The screened lime and sand being shovelled together, as little water as possible is added, after which the chafing and beating, or tempering in a pug-mill, takes place.

1862. Under this section, notice must be taken of a compound of ballast or stone chip-pings and lime mixed together, which has received the name of *concrete*, from the speedy concretion that takes place between the different particles whereof it is composed. If, however, *gallots* or small stone chippings are used, sand in a large proportion to the lime must be used. The use of concrete was well known at an early period, and is by no means, therefore, a discovery of modern days. Wherever the soil is soft, and unequal for the reception of the foundations of a building, the introduction of concrete under them is an almost infallible remedy against settlement. The Thames ballast, commonly used for concrete, is a mixture of sand and small stones. With this, and lime in the proportion of never

less than 4 to 1, and never properly exceeding 9 to 1, of stone lime, or such as is known to set hard in water, a mixture is made. The lime is generally used in powder, and the whole being shovelled together, it is wheeled in barrows to a stage over the spot where it is to be used, and let fall into the trench dug out for the reception of the foundation. The greater the height the concrete is made to fall, the sounder and stronger it becomes. It must always be recollected that no more lime is necessary than with the thinnest coat to surround the particles of the ballast, and that therefore the size of the pebbles or stones should influence the quantity of the lime. As the ground is more or less to be trusted, the thickness of the concrete must be regulated; when used on the best ground, a foot in thickness will be sufficient; while on the worst, as many as four feet or more may be required. The upper surface being levelled, it is usual to lay on it a tier of Yorkshire stone landings, for the reception of the brick-work or mason's work: in some cases, after carrying the wall a certain height, a second tier of landings has been introduced. When the soil is watery, no water should be put to the concrete, but the ballast and lime merely mixed and tumbled in. The stones or pebbles forming a portion of the concrete should never exceed the size of a hen's egg.

1863. The principal cements used in England are those generally known by the names of Parker's, Atkinson's, and Hamelin's mastic. The first named, also called Roman cement, is manufactured principally from stone found in the Isle of Sheppey, and at Harwich, being *septaria* from the London clay, and properly classed among the limestones indigenous to this country. It consists of ovate or flattish masses of argillaceous limestone arranged in nearly horizontal layers, chiefly found imbedded in the London clay. The substance being coated with a calcareous spar or sulphate of barytes, forms the basis of the cement. That now in use we do not think at all equal to the material originally employed. Thirty years ago it was possible to use it in the depth of winter; which, we apprehend, would be a hazardous thing to do with the cement at present made. Whether the inferiority arise from adulteration, bad manufacture, or the material being worse, we cannot pretend to say; we, however, do not believe that it arises from the badness of the raw material. If this cement be of extremely good quality, 2 parts of sand to 1 of the cement may be used. The cement itself is a fine impalpable powder; yet when wetted it becomes coarse, and, unless mixed with great care, it will not take a good surface. When mixed with the sand and water, it sets very rapidly; it is necessary, therefore, to avoid mixing much at a time, or a portion will be lost. The colour of this cement, when finished, is an unpleasant dark brown, and the surface requires frequent colouring. The great value of Parker's cement is its being impervious to water almost the moment it is used; hence it becomes highly serviceable on the backs of arches under streets, for the lining of cisterns, and for carrying up in it, or coating with it, damp walls on basement stories. It will not resist fire so well; and it should therefore never be employed for setting grates, ovens, coppers, or furnaces.

1864. Atkinson's cement is a good material, preferable in colour to the last named, but, as we think, inferior in quality. It takes a much longer time to set than Parker's cement, than which it absorbs more moisture. It answers well enough in dry situations.

1865. Hamelin's mastic cement, which, though patented of late years, is an invention of P. Lorient, a century old, is one in which the medium for mixing is oil instead of water. It is much more difficult to use than the other cements, and requires great experience and care in using. A coat of it should never exceed one quarter of an inch in thickness; hence it is totally unfit for working mouldings in the solid. In the metropolis it is generally used in a very thin coat over a rough coat of Roman cement, in which case it is rarely more than an eighth of an inch thick. Thus used, it not only presents a beautiful surface, but is extremely durable.

1866. The stones whereof the *Dutch tarra*s is made are found in the neighbourhood of Liege, and also, we believe, at Andernach on the Rhine, from the size of a pea to that of a middle-sized turnip. From their being brought down the rivers to Holland the cement has been called Dutch; the only operation they undergo in that country is the reduction of them to a coarse powder by means of mills. They are beaten by iron-headed stampers on an iron bed till they will pass through a sieve whose wires are about one eighth of an inch apart. This cement is sent from Holland in casks.

1867. The *Puzzolana*, or *terra Puteolana* of the Romans, which, as well as the last-named cement, has been almost if not quite superseded by the introduction of the Roman cement, is brought from Civita Vecchia. Its name is however derived from Puzzuoli, where it is principally found, though produced in other parts of Italy, in the neighbourhood of extinct volcanoes. It suddenly hardens when mixed with one third of its weight of lime and water, forming a cement more durable under water than any other. Bergman found 100 parts of it to contain 55 to 60 parts of siliceous earth, 20 of argillaceous, 5 or 6 of calcareous, and from 15 to 20 of iron; this last constituent is considered to be the cause of its property of hardening under water. The iron decomposes the water of the mortar, and thus in a very short time a new compound is formed. According to Vitruvius, when used for buildings in the water, 2 parts of *Puzzolana* were mixed with 1 of mortar.

## SECT. XII.

## GLASS.

1868. Glass is a combination of silix with fixed alkali, generally soda. The mixture when calcined receives the name of *frit*, which, after the removal of all its impurities, is conveyed to the furnace and melted in large pots or crucibles till the whole mass becomes beautifully clear, and the dross rises to the top. After being formed into the figures required, it is annealed or tempered by being placed in an appropriate furnace. The fineness depends on the purity and proportion of the ingredients. An extremely fine crystal glass is obtained from 16 parts of quartz, 8 of pure potash, 6 of calcined borax, 3 of flake white, and 1 of nitre. The specific gravity of glass is about 2600; of French plates, 2840; of English flint glass, 3320. Glass is extremely elastic, and less dilatable by heat than metallic substances.

1869. *Crown glass* is the best sort of window glass, differing from flint glass in its containing no lead nor any metallic oxide except manganese, and sometimes oxide of cobalt, in minute portions, for correcting the colour, and not as a flux. It is compounded of sand, alkali, either potash or soda, the vegetable ashes that contain the alkali, and generally a small portion of lime. To facilitate fusion, a small dose of arsenic is frequently added. Zaffre or oxide of cobalt, in the proportion of 1 ounce for 1000 pounds, is added, to correct the colour; but when the sand, alkali, and lime are very fine, and no other ingredients are used, zaffre is not required. In London were formerly made two sorts of crown glass. The Ratcliffe crown glass, which was the cheapest and best, whereof 24 tables went to the case; each table being 3 feet 6 inches diameter. The Lambeth glass was of a darker and greener colour. From the great disadvantage of manufacturing window glass where fuel is so dear, we have not now left a glass-house in the metropolis. Bristol and Newcastle are now the chief seats of its manufacture.

1870. The manufacture of common window glass is conducted differently from that of flint glass articles, the object being to produce a large flat thin plate of glass, which is afterwards by the glazier's diamond cut into the requisite shape. It is blown in circular plates, varying from 3 feet 6 inches to 4 and 5 feet diameter, and the process is as follows:—The workman, having a sufficient mass of melted metal on his blow-pipe, rolls it on an iron plate, and then, swinging it backwards and forwards, causes it by its own gravity to lengthen into a cylinder, which is made and brought to the required thinness by blowing with a fan of breath, which persons accustomed to the work know how to manage. The hollow cylinder is then opened by holding it to the fire, which, expanding the air confined within it (the hole of the blow-pipe being stopped), bursts it at the weakest part, and while still soft it is opened out into a flat plate by the centrifugal force; and being disengaged from the rod, a thick knob is left in its centre. It is then placed in a certain part of the furnace to undergo the process of annealing. When the table is cut for use, the centre part in which the knob remains is called *knob-glass*, and is used only for the commonest purposes.

1871. Tables are now made of such a size that squares may be procured 33 inches by 25, and even larger.

1872. The three qualities of glass in common use are called best, second, and third; the last is of a very green hue, and only used for inferior buildings. These are all of them sold by the *crate*, at the same price, the difference being made up by varying the number of the tables contained in it. Thus a crate of best crown glass contains twelve tables; of seconds, a crate contains fifteen; and of thirds, eighteen tables.

1873. German sheet glass was formerly much in demand here; but the great competition that has lately grown up in the manufacture of English plate glass, which has been much lowered in price, has brought this last into very extended use; and we seem likely to rival, if not surpass, the French in the manufacture of it.

1874. *Plate glass* is so called from its being cast in large sheets or plates. Its constituent parts are white sand, cleansed with purified pearl-ashes, and borax. If the metal should appear yellow, it is rendered pellucid by the addition, in equal small quantities, of manganese and arsenic. It is cast on a large horizontal table, and all excrescences are pressed out by passing a large roller over the metal. To polish it, it is laid on a large horizontal block of freestone, perfectly smooth, and then a smaller piece of glass, fastened to a plank of wood, is passed over the other till it has received a due degree of polish. For the purpose of facilitating the process, water and sand are used, as in the polishing of marble; and, lastly, Tripoli, smalt, emery, and putty, to give it lustre; but to give it the finishing polish the powder of smalt is used. Except in the very largest plates, the workmen polish their glass by means of a plank having four wooden handles to move it, and to this plank a plate of glass is cemented.

1875. Pliny gives the following account of the discovery of manufacturing glass, which

was well known in Aristotle's time, 350 B. C. "A merchant vessel, laden with nitre or fossil alkali, being driven on the coast of Palestine, near the river Belus, the crew accidentally supported the kettles on which they dried their provisions on pieces of the fossil alkali; the sand about it was vitrified by its union with the alkali, and produced glass." Though, according to Bede, artificers skilled in making glass were brought into England in 674, glass windows were not generally used here till 1180, and were for a considerable time esteemed marks of great magnificence.

## SECT. XIII.

## ASPHALTE.

1876. Asphalté is a calcareous bituminous substance, latterly introduced into this country chiefly for pavements, which (we speak of that of Seyssel) was first discovered at Pyrimont, a mountain on the eastern side of the Jura, and on the right bank of the river Rhone, one league north of the town of Seyssel, and has obtained its name from its intimate combination of asphaltum and other bituminous substances with pure carbonate of lime. The mountain is composed of blocks of stone, which being conveyed to the places where intended to be used, are there reduced to powder, 90 parts whereof are placed in a cauldron with 10 parts of mineral pitch, and exposed for a considerable time to a heat of 600 degrees of Fahrenheit. The substance thus obtained is used in a state of fusion, and in a few minutes after being laid down, it becomes so hard that it is, with a temperature of more than 100 degrees of Fahrenheit, susceptible of no impression. It is, however, said, nevertheless, to retain an elasticity, by which it adapts itself to all the action which, for its varied purposes, it is required to undergo. It has long been in use in the south of France, the footway of the Pont Moraud, a much frequented bridge, at Lyons, having been paved with it in 1827, and being, we believe, still in a very sound state. At Fort l'Ecluse, in the vicinity of the mountain, a small building covered with it has withstood the cold of forty Swiss winters, and is said still to continue in a perfect state of repair. For the last fourteen years, it has been occasionally used to cover the roofs of buildings in Paris, a purpose to which, for many reasons, we would not recommend its application in this country, though for a vast number of other objects it seems admirably adapted, such as foot pavements in streets, vaults, kitchens, passages, and all places where it is essential to exclude moisture, for barn floors, piggeries, farm yards, and the like.

1877. It is said (we have had no experience of it) to form with gravel a good concrete, where the soil is doubtful for bearing weight, and that it may be used as a cement for foundations, instead of mortar. It appears, from experience, not to be inflammable, a roof at Bordeaux adjoining a large house that was burnt there not having suffered, though all sorts of ignited materials fell upon it.

1878. In the years 1832, 1833, and 1834, the asphalté appears to have been successfully employed in constructing the fortifications at Vincennes, and also in the military works at Douay, Besançon, Bourbonne les Bains, Grenoble, and Lyons.

1879. Among the arguments used by the proprietors of the asphalté of Seyssel, here, where it is now, we believe, patented, over all the other sorts competing with it, are the following: — that the carbonate of lime and bitumen being combined in it by nature, it is *absolutely perfect* (these are their words), while in every artificial imitation the calcareous particles are merely enclosed by pitch; that the chalk is, consequently, unamalgamated, and the composition susceptible of the extremes of heat and cold. Another point of advantage whereon they insist is, that the asphalté of Seyssel consists in the large proportion of the calcareous matter to the bitumen, being about 83 to 17; while the combination effected by artificial means has never exceeded 60 of chalk to 40 of bitumen. The quantity, they say, of bitumen to be used should be the smallest that will hold the chalk in combination; and that therefore the manufactured article contains more than it should, and will consequently expand in summer and contract in winter.

1880. Making great allowances for the self-interest which the prospectus of every speculating company exhibits, we are, nevertheless, inclined to think that the asphalté of Seyssel is a valuable and important material for many building purposes, and have no doubt that it will be extensively used in this country. At present the price is high, as well from the cost of the material itself as from the necessity of procuring a solid foundation of concrete, or some other substance, whereon to lay it securely. There are several spots in the metropolis, as at Whitehall, for instance, where it has been used for foot pavements; but for other purposes we must abstain from recommending its application until experience shall justify the architect in its employment.

## CHAP. III.

## USE OF MATERIALS.

## SECT. I.

## FOUNDATIONS AND DRAINS.

1881. In the previous chapter, we have enumerated the principal materials used in building; we shall now proceed to show how those materials may be most advantageously employed; but we shall not, in the various branches of the practice, again touch on the materials themselves, which have been, we conceive, already sufficiently described. But previous to entering upon the different branches of practical building, we think it right to submit to the reader a few observations on that most important of all considerations—a due regard to the security of the foundations on which a building is to stand, as a preliminary to the works of the bricklayer and mason, as the case may be. No advance or improvement has been made in this branch of architecture, as a science, since the time of the ancients. The advice of Vitruvius may still be followed with safety. In England, the recent introduction of concrete has superseded the use of wood under walls in the earth; and piles are now quite exploded, except for the piers of bridges and other situations in which they can constantly be kept wet.

1882. The best soils for receiving the foundations of a building are rock, gravel, or close-pressed strong sandy earth; “but,” says L. B. Alberti, “we must never trust too hastily to any ground, though it may resist the pick-axe, for it may be in a plain, and be infirm, the consequence of which might be the ruin of the whole work. I have seen a tower at Mestre, a place belonging to the Venetians, which, in a few years after it was built, made its way through the ground it stood upon, which, as the fact evinced, was a loose weak soil, and buried itself in earth up to the very battlements. For this reason, they are very much to be blamed who, not being provided by nature with a soil fit to support the weight of an edifice, and lighting upon the ruins or remains of some old structure, do not take the pains to examine the goodness of the foundation, but inconsiderately raise great piles of building upon it, and out of the avarice of saving a little expense, throw away all the money they lay out in the work. It is, therefore, excellent advice, the first thing you do, to dig wells, for several reasons, and especially in order to get acquainted with the strata of the earth, whether sound enough to bear the superstructure, or likely to give way.” It is important, previous to laying the foundations, to drain them completely, if possible, not only from the rain and other water that would lie about, but from the land water which is, as it were, pent up in the surrounding soil. In soft, loose, and boggy ground, the use of concrete will be found very great; and in these soils, moreover, the width and depth it should be thrown in, should, as well as the lower courses of the foundation, be proportioned inversely to the badness of the soil. Clay of the plastic kind is a bad foundation, on account of the continual changes, from heat and moisture, to which it is subject, and which often cause it so to expand and contract as to produce very alarming settlements in a building. The best remedy against this inconvenience is to tie the walls together by the means of chain plates, buried in the centre of the footings, and on the top of the landings that rest on the concrete; these plates to be, of course, connected at the returning angles, so as to encompass the whole building. In these cases, the clay must be excavated to make room for the concrete. This will be found an effectual remedy in clay soils.

1883. If the soil be a sound gravel, it will want little more than ramming with heavy rammers; and if the building be not very heavy, not even that.

1884. Where vaults and cellars are practised, the whole of the soil must, of course, be excavated; but where they are not required, trenches are dug to receive the walls, which, in both cases, must be proportioned in strength to the weight of the intended superstructure and its height. In general terms, we may direct the depth of foundations to be a sixth part of the height of the building, and the thickness of the walls twice that of those that are raised upon them. Care must be taken that that which is to receive the footings of the walls be equable; otherwise, where external and internal walls are connected together, the former, being the heaviest, may settle more than the latter, thereby causing fractures, which, though not, perhaps, dangerous, are extremely disagreeable in appearance. The lower courses, which are called the footings of the wall, are often laid dry; and, perhaps, at all events, a sparing use of mortar in a spot loaded with the greatest pressure should be preferred. If the footings be of stone, very particular attention should be bestowed on

placing the stone in the courses in the same direction or bed as it lay in the quarry, to prevent its splitting.

1885. In foundations where, from columns or small piers pressing upon particular parts, there would be a liability, from uneven bearing, to partial failure, it has been the practice, from a very early period, to turn inverted arches (see *fig. 615.*) to catch on their springing the weight to be provided against, by which means such weight is equally distributed throughout the length of the foundation. "Standing thus," says our master Alberti, "they (the columns or weights) will be less apt to force their way into the earth in any one place, the weight being counterpoised and thrown equally on both sides on the props of the arches. And how apt columns are to drive into the ground, by means of the great pressure of the weight laid on them, is manifest from that corner of the noble temple of Vespasian that stands to the north-west; for, being desirous to leave the public way, which was interrupted by that angle, a free and open passage underneath, they broke the area of their platform, and turned an arch against the wall, leaving that corner as a sort of pilaster on the other side of the passage, and fortifying it as well as possible, with stout work, and with the assistance of a buttress. Yet this, at last, by the vast weight of so great a building, and the giving way of the earth, became ruinous."

Fig. 615.

1886. It is most important, when the walls are raised on the foundations, and brought up a little above the level of the earth, to take care that the earth, most especially if moist, should not lie against them; for if walls, before they are dry and settled, imbibe moisture, they rarely ever part with it, and thence gradually impart rot to the timbers throughout the house. In all buildings, it is an object to have a second thin wall outside the basement walls, so as to leave between it and them a cavity for the circulation of the air, such cavity being technically called an *air-drain*. This is in all cases desirable, but in moist and loose soils it is essentially necessary for the durability of the building, as well as for the health of those who are to dwell in it.

1887. We, perhaps, might have more properly spoken first of the subject of drainage and sewers, whereof it now becomes our duty to give some information, inasmuch as before a brick or stone of any building be laid, the architect neglects his duty if he has not provided for perfect drainage in the lowest parts of the structure. This must not be by the aid of a small stagnant tank, called a *cesspool*, often the cause of much disease in a family; but by means of a drain into some running stream at a distance from the building, or, if that be not practicable, into some far removed pond, whose exhalations shall not be blown by the prevalent winds of the spot back upon the place where they were generated, in a different form. Neither does the health alone of the family whose comfort is to be provided for, demand this consideration of drainage; for the durability of the structure is quite as much involved in good drainage as is the health of the family whose dwelling-place the house is to become: hence we are the more earnest in pressing the point. In cities, the architect cannot always accomplish this most important object to the extent of his desire; but in the country, he is unpardonable if he neglect so necessary a provision. In London and its suburbs, the laying down of efficient sewage has been gradually proceeding; and in half a century, should it proceed at the same rate that it has during the last fifteen years, we apprehend that there will be no city in Europe possessing so good a drainage.

1888. The main drain necessary for the service of the largest house (we suppose the case of one in the country), if the fall given it be even but moderate, requires no very large dimensions. When we recollect that a small river, draining a very considerable tract of country, is often in its section only 8, 9, or 10 feet superficial, it will easily be conceived that the surplus from, and rain water falling on a mansion, is a quantity, even at the most pressing times, requiring little area of discharge to free the place from damp. There are few cases in which the largest mansion would require, for its main branch of drainage, an area of more than 5 feet, which would be given by a sewer or drain 2 ft. by 2 ft. 6 in., supposing its section to be that of a parallelogram; but of course, where the fall permits, there is no objection to larger dimensions. It will be hardly necessary to recommend that drains should, as well for their durability as on other accounts, be constructed with curved bottoms. It is surprising that some (at least one) commissions of sewers about the metropolis should still persist in constructing their principal drains with flat bottoms, offering an additional impediment, by increased friction, to the more rapid discharge of the water. Thus, for instance, let us take the lower parts of two drains whose running depth of water is 1 foot, one whereof is formed with a semicircular bottom, 2 feet wide; the area of the column of water will therefore be 1.5708, and the length of the half curve will be 3.1416. To obtain, with one foot depth of water, the same area in a drain whose bottom is flat and

sides upright, we must have the width 1.5708, and the sum of the three sides touched by the water will be 3.5708. Then  $3.5708 - 3.1416 = .4292$  represents roughly the difference of friction or impediment in favour of the semicircular bottom in the case stated, nearly  $\frac{13}{100}$  of the power being lost by the use of a flat bottom.

## SECT. II.

### BRICKLAYING AND TILING.

1889. Bricklaying, or the art of building with bricks, or of uniting them by cement or mortar into various forms, includes, in the metropolis, and mostly in the provinces, the business of walling, tiling, and paving with bricks or tiles, and sometimes plastering; but this last is rarely, if ever, undertaken by the London bricklayer; though in the country the trades of bricklaying and plastering are usually united, and not unfrequently that of masonry also. The materials used have been described in a previous part of the work, to which the reader is referred (1811. *et seq.*).

1890. The tools used by the bricklayer, who has always an attendant labourer to supply him with bricks, mortar, &c., are — 1. A *brick trowel*, for taking up and spreading the mortar, and also for cutting the bricks to any required length. 2. A *hammer*, for cutting holes and chases in brickwork. 3. The *plumb rule*, being a thin rule, 6 or 7 inches wide, with a line and plummet swinging in the middle of it, in order to ascertain that the walls are carried up perpendicularly. 4. The *level*, which is about 10 or 12 feet long, with a vertical rule attached to it, in which a line and plummet are suspended, the use whereof is to try the level of the walls at various stages of the building as it proceeds, and particularly at the window cills and wall plates. 5. The *large square*, for setting out right angles. 6. The *rod*, for measuring lengths, usually 5 or 10 feet long. 7. The *jointing rule*, about 8 or 10 feet long, as one or two bricklayers are to use it, and 4 inches broad, with which they run or mark the centre of each joint of the brickwork. 8. The *jointer*, which is of iron, shaped like the letter S. 9. The *compasses*, for traversing arches and vaults. 10. The *raker*, a piece of iron having two knees or angles, dividing it into three parts at right angles to each other, the two end parts being pointed and equally long, and standing upon contrary sides of the middle part. Its use is to rake out decayed mortar from the joints of old walls for the purpose of replacing it with new mortar, or, as it is called, *pointing* them. 11. The *hod*, which is a wooden trough shut close across at one extremity and open at the other. The sides consist of two boards at right angles to each other, from the meeting whereof a handle projects at right angles to their union. It is used by the labourer for conveying bricks and mortar to the bricklayer; for which purpose, when he has the latter office to perform, he strews dry sand on its inside, to prevent the mortar from sticking. 12. The *line pins*, which are of iron, for fastening and stretching the line at proper intervals of the wall, that each course may be kept straight in the face and level on the bed. The pins have a line attached to them of 60 ft. to each pin. 13. The *rammer*, used for trying the ground, as well as for beating it solid to the utmost degree of compression. 14. The *iron crow* and *pick axe*, for breaking and cutting through walls or moving heavy weights. 15. The *grinding stone*, for sharpening axes, hammers, and other tools. The following ten articles relate entirely to the preparation and cutting of gauged arches. 16. The *banker*, which is a bench from 6 to 12 ft. long, according to the number of workmen who are to work at it. It is 2 ft. 6 in. to 3 ft. wide, and about 2 ft. 8 in. high. Its use is for preparing the bricks for rubbed arches, and for other gauged work. 17. The *camber slip*, a piece of wood usually about half an inch thick, with at least one curved edge, rising about 1 inch in 6 feet, for drawing the soffit line of straight arches. When the other edge is curved, it rises about half that of the other, that is, about half an inch in 6 feet, for the purpose of drawing the upper line of the arch, so as to prevent it becoming hollow by the settling of the arch. The upper edge is not always cambered, many preferring it straight. The slip being sufficiently long, it answers the width of many openings; and when the bricklayer has drawn his arch, he delivers it to the carpenter to prepare the centre for it. 18. The *rubbing stone*. This is of a cylindrical form, about 20 inches diameter, but may be less. It is fixed at one end of the banker, upon a bed of mortar. After the bricks for the gauged work have been rough-shaped by the axe, they are rubbed smooth on the rubbing stone. The headers and stretchers, in return, which are not axed, are called *rubbed returns* and rubbed headers and stretchers. 19. The *bedding stone*, which is a straight piece of marble 18 or 20 inches in length, of any thickness, and about 8 or 10 inches wide. It is used to try the rubbed side of a brick, which must be first squared to prove whether its surface be straight, so as to fit it upon the leading *skew back*, or leading end of the arch. 20. The *square*, for trying the bedding of the bricks, and squaring the soffits across the breadth of the bricks. 21. The *mould*, for forming the

face and back of the brick, in order to reduce it in thickness to its proper taper, one edge of the mould being brought close to the bed of the brick when squared. The mould has a notch for every course of the arch. 22. The *scribe*, a spike or large nail, ground to a sharp point, to mark the bricks on the face and back by the tapering edges of the mould, for the purpose of cutting them. 23. The *tin saw* used for cutting the sofite lines about one eighth of an inch deep, first by the edge of the level on the face of the brick, then by the edge of the square on the bed of the brick, in order to enter the brick axe, and to keep the brick from spalling. The saw is also used for cutting the sofite through its breadth in the direction of the tapering lines, drawn upon the face and back edge of the brick; but the cutting is always made deeper on the face and back of the brick than in the middle of its thickness, for the above-mentioned purpose of entering the axe. The saw is also used for cutting the false joints of headers and stretchers. 24. The *brick axe*, for axing off the sofites of bricks to the saw cuttings, and the sides to the lines drawn by the scribes. The bricks being always rubbed smooth after axing, the more truly they are axed the less labour will be requisite in rubbing them. 25. The *templet*. This is used for taking the length of the stretcher and width of the header. 26. The *chopping block*, for reducing the bricks to their intended size and form by axing them. It is made of any piece of wood that comes to hand, from 6 to 8 inches square, and generally supported upon two 14-inch brick piers, if only two men work at it; but if four men, the chopping-block must be lengthened and supported by three piers, and so on according to the number employed at it. It is about 2 ft. 3 in. in height. 27. The *float-stone*, which is used for rubbing curved work to a smooth surface, such as the cylindrical backs and spherical heads of niches, to take out the axe marks. It is, before application to them, made of a form reversed to the surface whereon it is applied, so as to coincide with it as nearly as possible in finishing.

1891. Before adverting to the *bond*, as it is technically called, of brick walling, which is the form of connection of the bricks with each other, we will stop to observe, that in working walls, not more than 4 or 5 feet should be brought up at a time; for as, in setting, the mortar shrinks and a general subsidence takes place, the part first brought up, if too large in quantity, will have come to its bearing before the adjacent parts are brought up, and thus fissures in the work and unequal settlements will take place. In carrying up any particular part above another, it should always be regularly sloped back to receive the adjoining parts to the right and to the left. On no account should any part of a wall be carried higher than one scaffold, except for some very urgent object.

1892. Previous to the reign of William and Mary, all the brick buildings in this island were constructed in what is called *English bond*; and subsequent to the reign in question, when, in building as in many other cases, Dutch fashions were introduced, we regret to say, much to the injury of our houses' strength, the workmen have become so infatuated with what is called *Flemish bond*, that it is difficult to drive them out of it. To the introduction of the latter has been attributed (in many cases with justice) the splitting of walls into two thicknesses; to prevent which, expedients have been adopted, which would be altogether unnecessary if a return to the general use of English bond could be established.

1893. In chap. i. sect. x. of this book (1550. *et seq.*) we have spoken generally on walls; our observations here, therefore, in respect of them, will be confined to brick walls and their bond.

1894. *English bond* is that disposition of bricks in a wall in which (except at the quoins) the courses are alternately composed of *headers* and *stretchers*. In brick walling, and indeed in stone walling also, a *course* means the horizontal layer of bricks or stones whereof the wall is composed, being contained between two faces parallel to the horizon, and terminated on each side by the vertical face of the wall. The mass also formed by brick or stones in an arch are also termed courses, but receive the name of concentric courses. The term header is applied to a brick or stone whose small head or end is seen in the external face of the wall; and that of stretcher, to a brick or stone whose length is parallel to the face of the wall. We are therefore to understand by English bond, a continuation either of header or stretcher, continued throughout in the same course or horizontal layer, and hence we have described it as consisting of alternate layers of headers and stretchers (*fig. 616.*), the former serving to bind the wall together in a transverse direction or widthwise, and thus prevent its splitting, whilst the latter binds it lengthwise, or in a longitudinal direction. None but the English bond prevents the former occurrence, as work executed in this way, when so undermined as to cause a fracture, separates, but rarely breaks through the solid brick, as if the wall were composed of one entire piece.

1895. The ancient Roman brickwork was executed on this

Fig. 616.

principle; and its extraordinary durability is as much to be attributed to that sort of work being used for bonding it together, as to its extraordinary thickness.

1896. In this, as well as Flemish bond, to which we shall presently come, it will be observed, that the length of a brick being but 9 inches, and its width  $4\frac{1}{2}$  inches, in order to break the joints (that is, that one joint may not come over another), it becomes necessary near the angles to interpose a quarter brick or *bat*, *a*, called a *queen closer*, in order to preserve the continuity of the bond in the heading course. The bond, however, may equally be preserved by a three-quarter bat at the angle in the stretching course, in which case this last bat is called a *king closer*. In each case an horizontal lap of two inches and a half is left for the next header. The figure above given is that of a two-brick or 18-inch wall, but the student will have no difficulty in drawing, on due consideration of it, a diagram of the bond for any other thickness of wall; recollecting, first, that each course is formed either of headers or stretchers. Secondly, that every brick in the same course and on the same face of the wall must be laid in the same direction, and that in no instance is a brick to be placed with its whole length against the side of another, but in such way that the end of one may reach to the middle of the others that lie contiguous to it, excepting in the outside of the stretching course, where three-quarter bricks, or king closers, will of course be necessary at the ends, to prevent a continued upright joint in the face of the work. Thirdly, that a wall crossing at right angles with another will have all the bricks of the same level course in the same parallel direction, whereby the angles will be completely bonded. We shall close these observations with a recommendation to the young architect, founded on our own experience, on no account, in any building where soundness of work is a desideratum, to permit any other than English bond to be executed under his superintendence.

1897. *Flemish bond* is that wherein the same course consists alternately of headers and stretchers, which, in appearance, some may fancy superior to that just described. Such is not our opinion. We think that the semblance of strength has much to do with that of beauty in architecture. But there is in the sufferance of Flemish bond a vice by which strength is altogether lost sight of, which we shall now describe. It was formerly, though now partially, the practice to face the front walls of houses with gauged or rubbed bricks, or with at least a superior species of brick, as the malm stock; in the former cases, the bricks being reduced in thickness, and laid with a flat thin joint frequently, what the workmen call a *putty joint*, for the external face, the outer and inner work of the same courses in the same wall, not corresponding in height, could not be bonded together except where occasionally the courses fell even, where a header was introduced from the outside to tie or bond the front to the internal work. Hence, as the work would not admit of this, except occasionally, from the want of correspondence between the interior and exterior courses, the headers would be introduced only where such correspondence took place, which would only occur in a height of several courses. Thus a wall two bricks in thickness, if faced on both sides, was very little indeed better than three thin walls, the two outer half a brick thick, and the middle one a brick or 9 inches thick. Bricklayers having little regard for their character will, if not prevented by the architect, not only practise this expedient, but will also, unless vigilantly watched, when a better sort of brick is used for the facing, cut the headers in half to effect a paltry saving of the better material. In walls of one brick and a half in thickness, the strength of the wall is not diminished by the use of Flemish bond so much as in those of greater thickness, as may be seen by the diagram (fig. 617.). Many expedients have been invented to obviate the inconveniences of Flemish bond; but we think it rather useful to omit them, lest we should be considered as parties to a toleration of its use, for the continuation whereof no substantial reason can be assigned. As we have before observed, all that can be alleged in its favour is a fancy in respect of its appearance: but were the English mode executed with the same attention and neatness bestowed on the Flemish method, we should say it was equally beautiful; and therefore we shall thus close our notice of it.

1898. The two principal matters to be considered in brick walling are, first, that the wall be as strong as possible in the direction of its length. Secondly, that it be so connected in its transverse direction that it should not be capable of separating in thicknesses. To produce the first, independent of the extraneous aid of bond timbers, plates, &c., it is clear that the method which affords the greatest quantity of longitudinal bond is to be preferred, as in the transverse direction is that which gives the greatest quantity of bond in direction of the thickness. We will, to exemplify this, take a piece of walling 4 bricks long, 4 bricks high, and 2 bricks thick, of English bond: in this will occur 32 stretchers, 24 headers, and 16 half headers to break the joint, or prevent one joint falling over another. Now, in an equal piece of walling constructed in Flemish bond, there will occur only 20

ELEVATION.

PLAN.

Fig. 617

stretchers and 42 headers; from which the great superiority of English bond may be at once inferred.

1899. Bond timber should be used in pieces as long as circumstances will admit. Some prefer its being laid in the centre of the wall, in which case, when dressings of wood are required on the interior face, wooden plugs must be provided to nail them to, which are not wanted where the bond timber is laid flush with the inner face of the wall.

1900. It will scarcely be necessary to inculcate the propriety of the mortar beds being as thin as possible. In good sound work they ought not to rise more than  $1\frac{1}{2}$  inches in four courses. The mortar or cement should be such as will quickly set, to prevent the superincumbent weight pressing the joints closer, and thereby causing settlements which, even with the greatest care, often take place unequally. As often as it is conjectured, from the nature of the soil, or from the foundation being partly new and partly old, that the work will not come to its bearing equally, it is better to carry up the suspected parts separately, and to leave at their ends what are called *toothings*, by which junctions may be made when the weaker parts have come to their regular sound bearing. The thickness of walls has furnished the subject of previous pages; we shall therefore only add, that too much care cannot be bestowed on strengthening all angles as much as possible, and well connecting the return of one wall into another; that piers or pilasters are exceedingly useful in strengthening walls, inasmuch as they act by increasing the base whereon the whole stands; and, lastly, that in carrying up walls to any considerable height, it is usual to diminish their thickness by *sets off* as they rise. In houses, above the ground-floor, the sets off are usually made on the inside, having the outside in one face; but, if it be possible, it is better to set off equally from both faces, because of the better balance afforded.

1901. A bricklayer, with the assistance of one labourer, will in one day lay about 1000 bricks in common walling; hence he would complete a rod of brickwork in four days and a half, its area being  $27\frac{1}{2}$  ft. superficial of the thickness of one brick and a half. When, however, there are many apertures or other interruptions to his work, he will be proportionably longer time over it. The weight of a rod of brickwork is about thirteen tons. Generally it may be taken as consisting of 4500 stock bricks, allowing for waste, 27 bushels of chalk lime, and 3 single loads of drift sand, or 18 bushels of stone lime and  $3\frac{1}{2}$  single loads of sand. In cement, of 36 bushels, and the same quantity of sharp sand.

1902. *Bricknogging* is a method of constructing a wall with a row of posts or *quarters* 3 feet apart, whose intervals are filled up with brickwork. It is rarely more than the width of a brick in thickness, and the bricks and timbers on the faces are flush. It should never be used where thickness can be obtained for a nine-inch wall.

1903. *Groined arches*. A groin is the angular curve formed by the intersection of two semi-cylinders or arches. When groins are formed of cones they are called conic groins; but our business here is with the more simple groins that occur in using brick arches. The centering for raising them belongs to the section Carpentry, to which the reader must refer. The turning a simple arch on a centre only requires care to keep the courses as close as possible, and to avoid the use of much mortar on the inner part of the joints. In executing a brick groin, the difficulty arises from the peculiar mode of making proper bond at the intersection of the two circles as they gradually rise to the crown, where they form an exact point. In the meeting or intersecting of these angles, the inner rib should be perfectly straight and perpendicular to a diagonal line drawn on the plan. After the centres are set, the application of the brick to the angle will immediately show in what direction it is to be cut. With respect to the sides, they are turned as for common cylindric vaults. The late Mr. George Tappen, an architect of great practical skill, introduced a method of constructing groins rising from octangular piers, which had the advantage of not only imparting strength to the angle, which in the common groin is extremely deficient, but of increasing the space for the stowage or removal of goods, and further, of strengthening the angles of the groin in this construction by carrying the band round the diagonals (*fig. 618.*) of equal breadth, and thus affording better bond to the bricks.

1904. Many ornamental brick cornices may be formed by but little cutting, and changing the position of the bricks employed, and several, indeed, without cutting, by chamfering only.

FIG. 618.

1905. *Niches* may be formed in brickwork. They constitute the most difficult part of the bricklayer's practice. The centre will be described under the section Carpentry. The difficulty in forming them arises from the thinness to which the bricks must be reduced at the inner circle, as they cannot extend beyond the thickness of one brick at the crown or top, it being the usual as well as much the neatest method to make all the courses standing.

1906. *Tiling* is the operation of laying the tiles on a roof for the covering of the building, and is effected with either plane tiles or pantiles, the former whereof is the most secure. Plane tiles are laid at different gauges; when laid at a six-inch gauge, 800 will cover a square; at a seven-inch gauge, about 690. A plane tile weighs from 2 lbs. to 2½ lbs.

1907. Pantiling is laid to a ten-inch gauge; and 180 pantiles, weighing from 5 lbs. to 5½ lbs. each, will cover a square. From the frequent repairs necessary to tiled roofs, slating has become the most useful covering, and is generally employed, except for the most common buildings.

1908. The tiler's tools are—the *lathing hammer*, with two gauge marks on it, one at 7 inches, the other at 7½ inches. The *lathing staff*, of iron, in the form of a cross, to stay the cross laths and clinch the nails. The *tiling trowel*, to take up the mortar and lay it on the tiles: it differs from the brick trowel, in being longer and narrower. The *bosse*, made of wood, with an iron hook, to hang on the laths or on a ladder, for holding the mortar and tiles. The *striker*, a piece of lath about 10 inches long, for separating and taking away the superfluous mortar at the feet of the tiles. The *broom*, to sweep the tiling after it is struck.

### SECT. III.

#### MASONRY.

1909. Masonry is the science of preparing and combining stones so as to tooth, indent, or lie on each other, and become masses of walling and arching for the purposes of building. The tools of the mason vary as the quality of the stone upon which they are to act. About the metropolis the value of stone is considerable; and it is accordingly cut into slips and scantlings by a saw moved horizontally backwards and forwards by a labourer. In those parts where stone is abundant, it is divided into smaller scantlings by means of wedges. The principal tools of the mason are the *mallet* and *chisels*, the latter being formed of iron, except at the steel end, and the cutting edge being the vertical angle. The end of the chisel struck by the mallet is a small portion of a spherical surface, and projects on all sides beyond the adjoining part or hand hold, which increases in magnitude towards the middle of the tool, to the entering or cutting edge. The other tools of the mason are a level, a plumb-rule, a square, a bevel, straight and circular rules of divers sorts, for trying surfaces in the progressive states of the work.

1910. In London, the tools used to work the face of a stone are, successively, the *point*, the *inch tool*, the *boaster* (the operation of working with which is called *boasting*, as that with the point is called *pointing*), and the *broad tool*. The use of the point leaves the stone in narrow furrows, with rough ridges between them, which are cut away by the inch tool, and the whole made smooth by the boaster. The point is from ¼ to ⅓ of an inch broad, the boaster is 2 inches wide, and the broad tool 3½ inches at the cutting edge, which in use is always kept perpendicular to the same side of the stone. It performs two sorts of operations. Thus, imagine the impression made by the whole breadth of the tool at the cutting edge to be called a cavity; in one operation, the successive cavities follow one another in the same straight line, until the breadth or length of the stone is exhausted; successive equidistant parallel lines are then repeated in the same manner, until the tool has passed over the whole surface. This operation produces a sort of fluted surface, and is called *stroking*. In the other operation, each successive cavity is repeated in new equidistant lines throughout the length or breadth of the stone; then a new series of cavities is repeated throughout the length and breadth of the stone; and thus until its whole length or breadth is gone through. This operation is called *tooling*. The tools for working the cylindrical and conical parts of mouldings are of all sizes, from ¼ of an inch upwards. Those for working convex mouldings are not less than half an inch broad, except the space be too confined to admit of such breadth.

1911. A stone is taken out of winding principally with points, and finished with the inch tool. In London, the squared stone used for facing buildings is usually stroked, tooled, or rubbed.

1912. In those parts of the country where the stone saved by the operation of sawing is not enough to compensate for the labour, the operation is altogether performed with the mallet and chisel.

1913. When stones, previous to the operation of hewing, are very unshapely, a *stone axe*, *jedding axe*, *scabbling-hammer*, or *cavil*, is used to bring the stone nearly to a shape ; one end of the jedding axe is flat, and is used for knocking off the most protuberant angular parts, when less than right angles ; the other end is pointed for reducing the different surfaces to nearly the intended form.

1914. In Scotland, besides the above described sorts of work, there are some other kinds termed *droved*, *broached*, and *striped*. Droving is the same as that called random tooling in England, or boasting in London. The chisel for broaching is called a *punch*, and is the same as that called a point in England. Broached work is first droved and then broached, as the work cannot at once be regularly done with the punch. Striped work must also be first droved and then striped. If broaching is performed without droving, which is sometimes done, it is never so regular, and the surface is full of inequalities. Of the three kinds of surfaces obtained, the droved is the cheapest.

1915. It is however to be observed, that the workman will not take the same pains to drove the face of a stone which is to be afterwards broached, as in that of which the droving is to remain the final finish. When the surface of stone is required to be perfectly smooth, it is accomplished by rubbing with sand or griststone, and it is called rubbed work. In Aberdeen, where the stone is very hard, being a granite, they use the scabbling hammer, by which they pick the stone until the surface has nearly acquired the requisite form. This sort of work is called *nidged-work*, and the operation *nidging*.

#### WALLING.

1916. In stone walling the bedding joints are usually horizontal, and this should always, indeed, be so when the top of the wall is terminated horizontally. In building bridges, and in the masonry of fence walls upon inclined surfaces, the bedding joints may follow the general direction of the work.

The footings of stone walls should be constructed with stones as large as may be, squared and of equal thicknesses in the same course, and care should be had to place the broadest bed downwards. The vertical joints of an upper course are never to be allowed to fall over those below, that is, they must be made as it is called to *break joint*. If the walls of the superstructure be thin, the stones composing the foundations may be disposed so that their length may reach across each course from one side of the wall to the other. When the walls are thick, and there is difficulty in procuring stones long enough to reach across the foundations, every second stone in the course may be a whole stone in breadth, and each interval may consist of two stones of equal breadth, that is, placing header and stretcher alternately. If those stones cannot conveniently be had, from one side of the wall lay a header and stretcher alternately, and from the other side another series of stones in the same manner, so that the length of each header may be two thirds, and the breadth of each stretcher one third of the breadth of the wall, and so that the back of each header may come in contact with the back of an opposite stretcher, and the side of that header may come in contact with the side of the header adjoining the said stretcher. In foundations of some breadth, for which stones cannot be procured of a length equal to two thirds the breadth of the foundation, the works should be built so that the upright joints of any course may fall on the middle of the length of the stones in the course below, and so that the back of each stone in any course may fall on the solid of a stone or stones in the lower course.

1917. The foundation should consist of several courses, each decreasing in breadth as they rise by sets off on each side of 3 or 4 inches in ordinary cases. The number of courses is necessarily regulated by the weight of the wall and by the size of the stones whereof these foundations or footings are composed.

A wall which consists of unhewn stone is called a rubble wall, whether or not mortar is used. This species of work is of two kinds, coursed and uncoursed. In the former, the stones are gauged and dressed by the hammer, and thrown into different heaps, each containing stones of the same thickness. The masonry is then laid in horizontal courses, but not always confined to the same thickness. The uncoursed rubble wall is formed by laying the stones in the wall as they come to hand, without gauging or sorting, being prepared only by knocking off the sharp angles with the thick end of the scabbling hammer.

1918. Walls are most commonly built with an ashlar facing, and backed with brick or rubble work. In London, where stone is dear, the backing is generally of brickwork ; which does not occur in the north and other parts, where stone is cheap and common. Walls faced with ashlar and backed with brick or uncoursed rubble are liable to become convex on the outside from the greater number of joints, and, consequently, from the greater quantity of mortar placed in each joint, as the shrinking of the mortar will be in proportion to the quantity ; and therefore such a wall is inferior to one wherein the facing and backing are of the same kind, and built with equal care, even supposing both sides to be of uncoursed rubble, than which there is no worse description of walling. Where a wall

consists of an ashlar facing outside, and the inside is coursed rubble, the courses at the back should be as high as possible, and the beds should contain very little mortar. In Scotland, where there is abundance of stone, and where the ashlar faces are exceedingly well executed, they generally back with uncoursed rubble; in the north of England, where they are not quite so particular with their ashlar facings, they are much more particular in coursing the backings. Course rubble and brick backings admit of an easy introduction of bond timber. In good masonry, however, wooden bonds should not be continued in length; and they often weaken the masonry when used in great quantity, making the wall liable to bend where they are inserted. Indeed, it is better to introduce only such small pieces, and with the fibres of the wood perpendicular to the face of the wall, as are required for the fastenings of battens and dressings.

1919. In ashlar facing, the stones usually rise from 28 to 30 inches in length, 12 inches in height, and 8 or 9 inches in thickness. Although the upper and lower beds of an ashlar, as well as the vertical joints, should be at right angles to the face of the stone, and the face and vertical joints at right angles to the beds in an ashlar facing; yet, when the stones run nearly of the same thickness, it is of some advantage, in respect of bond, that the back of the stone be inclined to the face, and that all the backs thus inclined should run in the same direction; because a small degree of lap is thus obtained in the setting of the next course, whereas, if the backs are parallel to the front, no lap can take place when the stones run of an equal depth in the thickness of the wall. It is, moreover, advantageous to select the stones so that a thicker one and a thinner one may follow each other alternately. The disposition of the stones in the next superior course should follow the same order as in the inferior course, and every vertical joint should fall as nearly as possible in the middle of the stone below.

1920. In every course of ashlar facing in which the backing is brick or rubble, *bond*, or, as they are called in the country, *through* stones should be introduced, their number being proportioned to the length of the course; every one of which stones, if a superior course, should fall in the middle between every two like stones in the course below. And this disposition should be strictly attended to in all long courses. Some masons, in carrying up their work, to show that they have introduced a sufficient number of bond stones into their work, choose their bond stones of greater length than the thickness of the wall, and knock or cut off their ends afterwards. But this is a bad practice, as the wall is liable to be shaken by the force used in reducing, by chiselling or otherwise cutting away the projecting part, and sometimes with the chance even of splitting the bond stone itself.

1921. In piers, where the jambs are coursed with ashlar in front, every alternate jamb stone should go through the wall, with its beds perfectly level. If the jamb stones are of one entire height, as is often the case when architraves are wrought upon them, and also upon the lintel crowning them, of the stones at the ends of the courses of the pier which are to adjoin the architrave jamb, every alternate stone should be a bond stone; and if the piers be very narrow between the apertures, no other bond stones will be necessary in such short courses. When the piers are wide, the number of bond stones is to be proportioned to the space. Bond stones, too, must be particularly attended to in long courses above and below windows. They should have their sides parallel, and of course perpendicular to each other, and their horizontal dimension in the face of the work should never be less than the vertical one. The vertical joints, after receding about three quarters of an inch from the face of the work with a close joint, should widen gradually to the back, so as to form hollow wedge-like figures for the reception of mortar and *packing*. The adjoining stones should have their beds and vertical joints filled with oil-putty, from the face to about three-quarters of an inch inwards, and the remaining part of the beds with well-prepared mortar. Putty cement is very durable, and will remain prominent when many stones are in a state of dilapidation, through the action of the atmosphere upon them. The use of the oil-putty is at first disagreeable, from the oil spreading over the surface of the contiguous stones; but after a time this unpleasant look disappears, and the work seems as though of one piece.

1922. All the stones of an ashlar facing ought to be laid on their natural beds. From inattention to this circumstance, the stones often flush at the joints; and, indeed, such a position of the lamina much sooner admits the destructive action of the air to take place.

1923. Where walls or insulated pillars of very small dimensions are to be carried up, every stone should be carefully bedded level, and be without concavity in the middle. If the beds should be concave, as soon as the superimposed weight comes to be borne by the pier or pillar, the joints will in all probability begin to flush; and it is moreover better, if it be possible, to make every course in the masonry of such a pier or pillar in one stone.

1924. When large columns are obtained in a single block, their effect, from that circumstance alone, is very striking; but as this is not very often to be accomplished, the next point is to have as few and as small joints as possible; and the different stones, moreover, ought to be selected with the view, as much as possible, of concealing the joints, by having

the blocks as much of the same colours as possible. It will immediately, of course, occur to the reader, that vertical joints in columns are inadmissible.

## COLUMNS.

1925. The stones for an intended column being procured, and the order in which they are to be placed upon one another having been determined, we must correctly ascertain the exact diameter for the two ends of each of them. To effect this, draw an elevation of the column proposed to its full size, divide it by lines parallel to the base into as many heights as the column is intended to contain stones, taking care that none of the heights exceed the lengths the stones will produce; the working of the stones to the diameters thus obtained then becomes easy. The ends of each stone must first be wrought so as to form exactly true and parallel planes. The two beds of a stone being thus formed, find their centres, and describe a circle on each of them; divide these circles into the same number of equal parts, which may, for example, amount to six or eight; draw lines across each end of the stone, so that they will pass through the centre and through the opposite divisions of the same end. The extremities of these lines are to regulate the progress of the chisel along the surface of the stone; and therefore, when those of one end have been drawn, those of the other must be made in the same plane, or opposite to them respectively. The cylindrical part of the stones must be wrought with the assistance of a straight edge; but for the swell of a column, a diminishing rule, that is, one made concave to the line of the column, must be employed. This diminishing rule will also serve to plumb the stones in setting them. If it be made the whole length of the column, the heights into which the elevation of the column is divided should be marked upon it, so that it may be applied to give each stone its proper curvature. But as the use of a very long diminishing rule is inconvenient when the stones are in many and short lengths, rules or rods may be employed corresponding in length to the different heights.

## STAIRS.

1926. Nothing to perplex will occur in carrying up stairs which are supported by a wall at both ends, because the inner ends of the steps may either terminate in a solid *newel*, or be tailed into a wall surrounding an open newel. Where elegance is not required, and where the newel does not exceed 2 feet 6 inches, the ends of the steps may be conveniently supported by a solid pillar; but when the newel is thicker, a thin wall surrounding the newel would be cheaper. In stairs to basement stories, where geometrical stairs are used above, the steps next to the newel are generally supported upon a dwarf wall.

1927. In *geometrical stairs*, the outer end of each step is fixed in the wall, and one of the edges of every step supported by the edge of the step below, and formed with *joggled* joints, so that no step can descend in the inclined direction of the plane nor in a vertical direction; the sally of every joint forms an exterior obtuse angle on the lower part of the upper step, called a back rebate, and that on the upper part of the lower step of course an interior one, and the joint formed of these sallies is called a *joggle*, which may be level from the face of the risers to about one inch within the joint. Thus the plane of the tread of each step is continued one inch within the surface of each riser; the lower part of the joint is a narrow surface, perpendicular to the inclined direction or soffit of the stair at the end next to the newel.

1928. With most sorts of stone the thickness of every step at the thinnest place need not exceed 2 inches for steps of 4 feet in length; that is, measuring from the interior angle of every step perpendicular to the rake. The thickness of steps at the interior angle should be proportioned to their length; but allowing that the thickness of the steps at each of the interior angles is sufficient at 2 inches, then will the thickness of them at the interior angles be half the number of inches that the length of the steps is in feet; for instance, a step 5 feet long would be  $2\frac{1}{2}$  inches at that place.

1929. The stone platforms of geometrical stairs, that is, the *landings*, *half paces*, and *quarter paces*, are constructed of one or more stones, as they can be procured of sufficient size. When the platform consists of two or more stones, the first of them is laid on the last step that is set, and one end tailed in and wedged into the wall; the next stone is joggled or rebated into the one just set, and the end also fixed into the wall, as that and the preceding steps also are; and every stone in succession, till the platform is completed. When another flight of steps is required, the last or uppermost platform becomes the spring stone for the first step of it, whose joint is to be joggled, as well as that of each succeeding step, similarly to those of the first flight. The principle upon which stone geometrical stairs are constructed is, that every body must be supported by three points placed out of a straight line; and therefore, that if two edges of a body in different directions be secured to another body, the two bodies will be immovable in respect to each other. This last case occurs in the geometrical staircase, one end of each stair stone being tailed into the

*of arch stones.* Find the centres  $e, f, g$  in the same manner as if the arch were to be drawn; join  $ge$  and produce it to meet the arch; also join  $g, f$  and produce it to meet the arch in  $i$ . Divide the elliptical curve  $ADB$  into as many equal parts as the number of arch stones. From the centre  $e$  draw lines through the points of division in the curve between  $A$  and where  $ge$  meets the curve, and from the centre  $g$  draw lines through all the intermediate points between  $ge$  and  $gf$ , and lastly draw lines from  $f$  through all the intermediate points between  $i$  and  $B$ , and the parts of the lines thus drawn on the outside of the curve will be the joints of the arch stones.

1936. In very large arches it will be desirable to find five centres, as in *fig. 622.*, and these will be obtained by finding two intermediate points in each half of the curve instead of one; then bisecting each pair of adjacent points by a perpendicular, we shall have the centres  $e, h, g, i, f$ , to be used for drawing the joints in the same manner as in the preceding figure.

1937. The above methods are sufficient for ordinary purposes; but where strict accuracy is required, the following method is mathematically true. Suppose any joint, as  $gh$ , is required to be drawn (*fig. 623.*), and that the point  $D$  is the middle of the arch and the point  $C$  the middle of the springing line; then with the distance  $CA$  or  $CB$ , from the point  $D$  describe an arc at  $e$  and another at  $f$  to cut  $AB$  at  $e$  and  $f$ . Draw  $eg$  and  $fg$ ; produce  $eg$  to  $i$  and  $fg$  to  $h$ , bisect  $hgi$  by the straight line  $gk$ , which will be the joint required. In the same manner, by drawing lines from  $e$  and  $f$  to each point of division, and bisecting the angle, lines for the other joints may be drawn.

1938. To draw a Gothic arch to any given dimensions (*fig. 624.*). Draw the straight line

Fig. 622.

Fig. 623.

Fig. 624.

Fig. 625.

$AB$  equal in length to the span of the arch. Bisect  $AB$  in  $C$  by the perpendicular  $DI$ . and draw  $AG$  and  $BH$  parallel to  $DI$ . Make  $CD$  equal to the height of the arch, and the angles  $CDG$  and  $CDH$  each equal to half the vertical angle; make  $CF$  equal to the difference between  $CD$  and  $AG$  and join  $FA$  and  $FB$ . Divide  $AG$  and  $AF$  each into the same number of equal parts, counting each from the point  $A$ . Through the points 1, 2, 3, 4 in  $AF$  draw  $Ia, Ib, Ic, Id$ , and through the points 1, 2, 3, 4 in  $AG$  draw  $1D, 2D, 3D, 4D$  cutting  $Ia, Ib, Ic, Id$  at the points  $a, b, c, d$ , then through the points  $AabcdD$  draw a curve; which will be half of the Gothic arch required.

1939. To draw the joints of the arch stones of a Gothic arch (*fig. 625.*). Having formed the angles  $CDG$  and  $CDH$  as before, make  $Ai$  equal to  $AG$  and draw  $DI$  perpendicular to  $DG$ . In  $DI$  make  $Dk$  equal to  $Ai$  and join  $ik$ . Bisect  $ik$  by a perpendicular meeting  $DI$  in  $l$ . Produce  $li$  to  $p$ . Divide the curve into as many equal parts as the arch stones are to be in number. Then  $i$  will be the centre of the joints which pass through all the

points between A and *p*, and *l* will be the centre for drawing the joints of the arch stones which pass through all the points between *p* and D.

1940. The reason for the foregoing rule is obvious; for the joints are merely made to radiate to the centres of the arcs of circles whereof the arches themselves are formed; as in subsections 1934, 1935. they were drawn to the centres of the approximating circles wherefrom the elliptical curves were struck.

1941. To describe a parabolic curve for a pointed or Gothic arch by means of a series of lines touching the curve, the dimensions of the arch and the angles it forms at the crown being given. Draw the straight line AB (fig. 626.) and draw CD perpendicular to AB. Make CD equal to the height of the arch, CA and CB each equal to half the span. Make the angles CDe and CDf each equal to half the vertical angle. Divide Ae and eD each into the same number of equal parts, and through the corresponding points of division draw lines which will form one half of the arch: the other half DB may be found in the same manner.

Fig. 626.

1942. To draw the joints of the arch stones in the above sort of arch. Draw the chords AD, DB for each half of the arch (fig. 627.); divide the arch into as many equal parts as there are to be arch stones. Let it now be required to draw a joint to any point *h*: bisect AD in *k*, and join *ek* cutting the curve in *l*. Draw *hg* parallel to *Ak*, cutting *ek* in *g*, and in *el* make *li* equal to *lg*. Join *hi* and draw *hm* perpendicular to *hi*. Then *hm* is the joint required. In the same manner all the remaining joints will be found.

Fig. 627.

1943. To describe a rampant pointed arch, whose span, perpendicular height, and the height of the ramp are given. Draw the straight line AB (fig. 627.), and make AB equal to the span of the arch. Draw BC perpendicular to AB, and make BC equal to the height of the ramp. Bisect AC in D, and draw DE perpendicular to AB. Make DE equal to the height of the arch; draw Af and Cg parallel to DE, and make Af and Cg equal to about two thirds of DE. Join fE and Eg. Divide Af and fE each into the same number of equal parts, and through each two corresponding points of division draw a straight line. All the lines thus drawn will give one half of the curve. The other half may be drawn in the same manner. To find the joints (fig. 629.) proceed as for a plain arch in the last example.

Fig. 628.

1944. II. OF THE CONSTRUCTION OF INTERSECTING VAULTS OR GROINS. The forms of vaults may be so adapted to one another that the lines of intersection shall be in planes, and these planes the diagonals of the plan of the intersecting part of the vaults; if, however, they be not so adapted, the lines of intersection will be curved on the plan, and these curves it is necessary to ascertain in making both the moulds and the centerings for executing the work.

1945. To determine the form of a vault to intersect with a given one in the plane of the diagonal, and also to find the diagonal rib for the centering. Let the given vault be EIF (fig. 630.) and AC and BD the diagonals, crossing in *f*. Draw *fI* perpendicular to EF, cutting EF in *c*. In the arc IF take any number of points *ab*, and draw *ag*, *bh* parallel to *If*, cutting EF in *d*, *e*, and the diagonal AC in *g*, *h*. Draw *fp*, *gq*, *hr* parallel to EF, cutting the base GH at *m*, *n*, *o*. Make *mp*, *ng*, or each respectively equal to *cI*, *da*, *eb*. Draw *fI'*, *gk*, *hl*, perpendicular to AC, and make *fI'*, *gk*, *hl* respectively equal to *cI*, *da*, *eb*. Make

Fig. 629.

Fig. 630.

Fig. 631.

$fg'$ ,  $fh'$  each respectively equal to  $fy$ ,  $fh$ . Draw  $g'h'$ ,  $h'l'$  parallel to  $f'l'$ . Make  $g'h'$  equal to  $gk$ ,  $h'l'$  equal to  $hl$ ; also make  $mn'$ ,  $m'o'$  each respectively equal to  $mn$ ,  $mo$ . Draw the arcs  $pqr$ ,  $p'q'r'$ , as also  $l'kl'$ ,  $l'k'l'$ ; then, through the points thus found, draw the curves upon their bases AC and GH, and that on GH is the form of the intersecting vaults, and that on AC is the form of the angle rib. If the form of the given arch be that of a semicircle EIF (fig. 631.), let ABCD be the angular points of the plan, AC and DB the diagonals, cutting each other at M. Draw MK parallel to GD, or CH cutting GH in N. Draw ML perpendicular to AC, and make ML equal to the radius of the semicircle. Then, with the transverse axis AC, and semi-conjugate axis ML, describe a semi-ellipse, which will be one of the angle ribs, as required. Also make NK equal to the said radius; then with the lesser axis and the semi-greater axis NK describe the semi-ellipse GKH, which is the form of the other vault.

1946. The same method applies in fig. 632., where the narrow opening is a semi-circle,

Fig. 632.

Fig. 633.

and the wide one, consequently, a semi-ellipse, having its minor axis vertical and its major axis horizontal.

1947. When two circular-arched vaults of different heights intersect, to determine the plan of the arrises in which the arches meet. Let ABC (fig. 633.) be the arch of the main vault, and DEF that of the lesser vault; ACLO the plan of the main vault, and DPQF that of the lesser vault; and let the two vaults intersect each other at the points HKNM. Also, let E be the middle point of the lesser semi-circular arch DEF. Produce HD to  $r$ , and in the arch DE take any number of points  $rs$ , and draw  $rb$ ,  $sa$ , EI parallel to DH. Draw  $rt$ ,  $su$ ,  $Ev$  parallel to DF, cutting Dv at the points  $tuv$ , and produce HC to G. In CG make Cw, Cx, CG respectively equal to Dt, Du, Dv, and draw  $wz$ ,  $xy$ , GB parallel to AC, cutting the semi-circle ABC in the points  $zyB$ . From the points  $Byz$  draw BI,  $ya$ ,  $zb$ , parallel to CL. Then through the points  $Iab$  draw a curve, which will be one half of the plan of the arris. The other half will be found in the same manner.

1948. The method of tracing the plan of the groins is the same (see fig. 634.) when the vaults intersect obliquely.

1949. To find the plan of the intersections of two arches of the same height, and either of the same or different species. Let the sections of the two arches be ABC and DEF (fig. 635.), the arcs AB, BC being equal to each other, and the arcs DE, EF equal to each other;

Fig. 634.

Fig. 635.

and let H, K, N, M be the points where the two arches intersect each other on the plan. Divide either of the arcs BC or DE into parts, equal or unequal; as, for example, in the arc DE take any number of points  $r, s$  at pleasure, and draw  $ra, sb, EI$  perpendicular to DF. Produce HD to  $v$ , and draw  $rt, su, Ev$ , parallel to DF, cutting Dv in  $t, u, v$ . Produce HC to G, and make Cw, Cz respectively equal to Dt, Du; and as the arches are equal in height, CG will be equal to Dv. Draw  $wy, xz$ , GB, parallel to AC, cutting the arc BC in the points  $y, z$ , and touching it in B. Draw  $ya, zb$  and BI parallel to HK, and through the points  $HabI$  draw the curve  $HabI$ , which will be half the plan of the groin as required. The other half IN and the other groin MK will be found in the same manner.

1950. To find the plan of the groins produced by the intersection of a cylindric and a conic vault, the angle of position of the axis, the diameter of the cylinder, and the plan of the conic vault being given. Let AB (fig. 636.) be the axis of the cylinder, CD that of the cone, C being the apex, and D the point through which the base passes. Through any point A in AB draw EF perpendicular to AB, and make AE and AF each equal to the radius of the cylinder, and draw EH and FI parallel to AB. Through D draw KM perpendicular to CD, and make DK and DM each equal to half the diameter of the cylinder. Join KC and MC, cutting EH and FI in the points N, O, P, Q. Divide the semicircles FGE and KLM into parts, whereof the corresponding ones are equal to one another. From the points of division in the semicircle EGF draw lines parallel to AB; and through the corresponding points in the semicircle KLM draw lines perpendicular to the diameter KM, cutting KM. From the points of section draw lines to the apex C of the cone, cutting the former drawn through the points in the semicircumference FGE. Through each set of corresponding points draw a curve, and the two curves will represent the arrisses of the groin on the plan. If in an octagonal ground vault the octagonal range be cylinders, and the cross vaults, which tend to the centre, diminish to a line of the height of the vault, the following construction applies:—Let EFGHI (fig. 637.) be the exterior side of the vault, which is both equilateral and equiangular, and let JKLMN be the line of the exterior surface of the inner wall; so that the lines EJ, FK, GL, HM, IN, which pass through every two corresponding angles, may tend to the centre O of the groin vault. Let the sections of the given ribs be PQR and STU, so that PR of the rib PQR may stand at right angles to the sides EF and JK and the side SU of the rib STU on the middle of the side FG. Divide the two bases PR and SU in the same proportion, and through the joints of division in SU draw lines from the centre O of the ground vault to meet the curve STU; and

Fig. 636.

Fig. 637.

through the points of division in the base PR of the cross rib PQR draw lines parallel to EF, to terminate in the line FK, and in the semicircle PQR. From the points where these lines meet FK, draw perpendiculars on one side of FK, and make the heights of these perpendiculars respectively equal to the ordinates of the arc PQR; and through the ends of these perpendiculars draw a curve FVK, which will be the angle rib. From the points of meeting in the line FK draw lines parallel to FG, and through the points of division in SU draw lines to the centre O, intersecting the former lines drawn from the points of division in FK; through the corresponding points of intersection draw the curves SBL and KBU, which will form the plan of the angle.

1951. In single groins the centres are made for the widest avenue, and are covered over with boards (*fig. 638.*), so that the top of the boards may form the surface required for

Fig. 638.

Fig. 639.

turning the arch upon the intersections; or the angles are found by the following practical method. The groins meet in the points I, C (*fig. 639.*), upon the boarding of the two groins. Place the straight edge of a board upon the point I, so as to range over the line GH on the plan. Then set up another straight edge upon the point H, so as to be vertical, and the straight vertical edge will meet the horizontal edge; then apply a third straight edge to each of the other two straight edges, so that it may also come in contact with the boarding. After this draw a line along this third straight edge upon the boarding as far as may be found convenient; shift the moveable or third straight edge, and apply it in the same manner to another adjoining portion of the surface of the boarding. Proceed in the same manner until the whole line be completed on the surface. By this means, the necessity of laying down lines for the covering is avoided. The lines being thus drawn, ribs for the cross vaults are fixed on the top of the boarding; so that, making proper allowance for the thickness of the same, its surface, when fixed, may form the true surface of the other cross vault. The ribs fixed upon the boarding to form the cross vaults are called *jack ribs*.

1952. The mode of constructing the curves by lines is shown for a rectangular groin in *fig. 640.*, in which A is the plan, B the elevation. Here, to find the pliant moulds for forming the groins on the surface of the boarding, and working the arch-stones, describe a semicircle on one of its sides, and divide it into any convenient number of equal parts. Draw lines perpendicular to the base or diameter, the semicircle being supposed to be within the piers; the ordinates will cut the diagonals; but if it be laid down on the outside, the ordinates must be produced until they cut the diagonals. From the points where the ordinates cut the diagonals, draw lines parallel to the other side of the groin, and produce the side on which the diameter of the semicircle is placed, and extend the semicircular arc with its divisions upon any convenient part of the line thus produced. Through the points of division draw perpendiculars, so as to intersect with the former parallel lines; then through the points of intersection draw the curve, as shown at C, which will be the mould required.

1953. Sometimes several vaults meet in one common centre, as in *fig. 641.*, which exhibits the plan of an equiangular and equilateral groined vault, constructed of semicircular arches.

Fig. 640.

Fig. 641.

Fig. 642

1954. Where the piers supporting groins (*fig. 642.*) are made octangular, the angles of the groins should be cut off or arched as ribs, by which they are rendered much stronger than when they are square. In stone groins, where the arch is cut off, there is no advantage in point of strength, and rather a defect in point of appearance, to the groined angles.

1955. Arches intersecting a coved ceiling are similar to groins. Such arches are called *lunettes*, and are generally practised for semicircular-headed windows piercing the coves in the ceiling: *fig. 643.* exhibits a plan and section of such arches.

1956. A dome is a solid, which may be conceived to be generated by the figure of the base diminishing as it rises, till it becomes a point at the summit; and when a dome has a polygonal base, the arches are plain arches, and the construction is similar to that of a groin. A domed ceiling of this kind upon a rectangular plan is shown in plan B (*fig. 644.*); the sections A A being elliptical in the top, and with lunette windows. C shows the geometrical construction.

Fig. 643.

Fig. 644.

1957. *When arches intersect an inclined vault, and the projections of the arrisses cross each other at right angles, and the angle of elevation of one of the semicircular vertical ribs of the ascending avenue or opening is given to obtain the geometrical construction; so that the cross arches may be cylindrical surfaces.*

Draw the straight line AB (fig. 645.) to represent the axis of the inclined vault, and draw CD perpendicular to AB. Produce D to *e* and *h*; make AC and AD each equal to the radius which forms the edges of the ribs; draw *hN* parallel to AB, and make the angle *NhO* equal to the inclination of the axis represented by its plan AB. In the line *hO* take any point *p*, and draw *hq* parallel and *ps* perpendicular to *hN*. Make *ps* equal to AC or AD, and through *s* draw *Lt* parallel to *hO*. Draw *pu* perpendicular to *Lt*, cutting it in *u*. Produce *pu* to *v*. Set the circumference of the inclined vault from *u* to *r*, divided into the equal parts *u*, 1, 1, 2; 2, 3; 3*v*, at the points 1, 2, 3. Divide each of the quadrants *qs*, *sr*, into the same number of equal parts at the points 1, 2, 3, and through these points and in *uv* draw *1a*, *2b*, *3c* parallel to *vt*, and through the points 1, 2, 3, in the curve *qs*, draw *1L*, *1a*, *2b*, *3c*, parallel to *pu*. Through all the points *L*, *a*, *b*, *c* draw the curve *Labc*, and this will be the pliable mould for forming the angle of groin over the plan, and for working the arch stones. Draw *Dk* parallel to *Az*. Let *E* divide the circumference *CED* into the two equal parts *EC*, *ED*; divide the arcs *DE*, *EC* into the same number of equal parts as *uv* at the points 1, 2, 3, and draw *1u*, *2x*, *3y*, *Ez*, parallel to *AB*; also through the points 1, 2, 3 in the quadrant *qu* draw *gk*, *1u*, *2x*, *3y*, *uz*, perpendicular to *yN*; then through the points *k*, *u*, *x*, *y*, *z*, draw a curve, which will be the plan of the groin whereof the stretch-out is *Labc*. In the same manner the other half of the plan will be found, as also the whole of the other parts.

Fig. 645.

1958. *The form of an arch crossing an inclined groined vault at right angles, and the plan of the diagonal ribs being given; to find the arch of the level vault.* Let AB, BC (fig. 646.) be the plan of the axis of the vaults. Through any point A in AB draw DF perpendicular to AB, and make AD and AF each equal to the horizontal breadth of the vault. Draw DG and FH parallel to AB; draw also any line LK parallel to AB, cutting BC in C, and make the angle KIL equal to the inclination of the axis represented by its plane AB. Make CM and CK equal to the breadth of the level vaults; draw KG and MN parallel to BC, and let MN cut DG in N, and FH in P. Draw the diagonals PG and NH. Produce GK to cut IL in L, and NM to cut IL in Q. In the curve DEF take any number of points *a*, *b*, *c*, and draw *ad*, *be*, *cf* parallel to AB, cutting DF in the points *p*, *q*, *r*, and the diagonal GP in *d*, *e*, *f*, and the diagonal HN in the points *d'*, *e'*, *f'*. Produce BA to E, draw *dl*, *em*, *fn*, Bo parallel to BC, cutting QL in the points *g*, *h*, *i*; make *gl*, *hm*, *in*, *ko* equal respectively to *pa*, *qb*, *rc*, AE; then through the points *l*, *m*, *n*, *o*, draw the curve *QoL*. Draw HR perpendicular to NH, and make HR equal to KL, and join NR; then will HR be the line of ramp for the diagonal rib over its plan HN. Perpendicular to HN, draw *dv*, *ew*, *fy*, BG cutting the line of ramp RN in the points *s*, *t*, *u*, *v*. Make *sv*, *tw*, *uy*, *vg* respectively equal to *pa*, *qb*, *rc*, AE. Then through all the points *v*, *w*, *y* draw a curve, which will be the angle rib standing over HN, and which will also serve for the angle rib standing over GP. All the groined vaults continued in the same range may be constructed by the same moulds.

Fig. 646.

1959. *To make the working drawings for a semicircular arch with a straight face, and to describe the moulds for the voussoirs.* This simple case will serve as a rule for those following; hence the explanation should be perfectly understood, as all the other cases differ

from it only according to the different kinds of arches to be constructed; such as the *bevelled arch*, that in a *battering or sloping wall*, and that on a *circular wall*.

1960. Draw two lines (fig. 647.) perpendicular to and crossing each other, as BA, GD From the point E, as a centre, describe the sofitte curve ACB, and the extrados or upper curve FGH. Divide each of these arcs into two equal parts, as the dotted arc *abc*. Draw LM parallel to AB, and make the distance A'L equal to the thickness of the wall wherein the arch is to be constructed. Draw the outer and inner lines of the plan F'K, A'L, B'M, HN parallel to CD. Divide the arc ACB into the proper number of equal parts for the arch stones or voussoirs, suppose five, by the joint lines 1, 2, 3, 4; from the point E draw the joints 1—5, 2—6, 3—7, 4—8; then from every point where the joints cut the arcs ACB, FGH, &c. draw the lines 8c4, 7h3, &c. On KN let fall the perpendiculars 8d, cM, 4f, hi, 3k, 2l, mn, 6o, 1p, aL, and 5s. Divide the sofitte of each voussoir A1, 1—2, 2—3, &c. into two equal parts in t, u, v, w, from which all also let fall the perpendiculars tY, uX, vV, wT.

1961. To draw the moulds of the sofitte below NK. Draw the line OP parallel to the line KN; prolong ED to Z and make the distance QZ equal to ED. Through Z draw RS parallel to OP, and on each side of QZ lay off the distances C3, 3v, v4, 4w, and wB respectively on Qx, xy, ya, ab, and bP. On the other side lay off C2, 2u, u1, 1f and fA on Qc, cd, de, ef, and fO. Through the points O, e, c, x, a let fall on RS the perpendiculars OR, ea', cd', xc', ad, PS, and through the points f, d, y, b let fall the perpendiculars from the middle sheetings fe', df', yg', bh'; the distances of the dark lines give the breadth of the sofitte of each stone in the sofitte curve.

1962. To draw the moulds of the joints: lay off the distance 1—5 on eg, ch, xi, ah, and through the points ghin draw the lines gg, hl, im, kp, parallel to QZ. To find the middle of the joint divide the distances eg, ch, xi, an, each into two equal parts, as in k', m', g', s, through which draw the lines k'l', m'n', q'r', s't parallel to QZ.

1963. The elevation is a section of a hollow cylinder, of which the concave or interior surface forms the intrados of the arch, and the convex or exterior surface the extrados, and of which the cutting plane of the section is perpendicular to the common axis of the cylinder.

1964. The angles of the stone are found from the angle which the arc of this section makes with any joint, and the curving of the sofitte of the stone is found by a ruler or mould, the edge of which is made to the curve. The ends of the sofitte are found by its development.

1965. When the stones are shaped according to the moulds, and joined together in consecutive order, the whole mass, thus united, will form the solid arch as required.

1966. These separate operations being properly attended to, every difficulty will be removed, and no confusion will arise during the process, which can, in any degree, tend to perplex the delineator.

1967. To find the bevels and moulds for the joints and sofitte of an elliptical arch cutting obliquely through a straight wall, the joints radiating to the centre of the opening. Draw the axis EN of the arch (fig. 648.), and therein take any point E, through which draw AB perpendicular to EN; make EA and EB each equal to half the space of the extrados or centre line of the arch; also make EC and ED each equal to half the span of the inner arch. Produce the diameter NE to G;

FIG. 647.

FIG. 648.

make EF equal to the height of the inner arch and EG equal to the height of the outer arch. On the major axis AB, and semi-minor axis EG, describe the semi-ellipsis AGB, which is the extrados of the arch. Also, on CD as the major axis, and EF the semi-minor axis, describe the semi-ellipsis CFD.

1968. Make the angle ABH equal to the angle which the wall makes with the right section of the arch, and let BH cut the axis in K. Draw ML at such a distance from BH that they may comprehend between them the thickness of the wall, and let ML cut the axis in N. The intrados of the arch on the one side of the wall is OPR, and the extrados is LQM; they are both ellipses respectively of the same height as the intrados and extrados of the right arch, but with the axes OR and LM.

1969. To find the bevel of the angle of the arch stones corresponding to the joint ab tending to the centre E. Describe the arc bc from E with the radius Eb cutting AB in c. Draw bg parallel to EN cutting BH in g, and draw cd parallel and gd perpendicular to EN, and join KD; then EKD is the angle or bevel required.

1970. The sofitte of the arch is drawn according to the general principles of development.

1971. To make the working drawings for an arch in a sloping wall, as, for instance, an arch in a terrace wall. To draw the elevation; from any convenient point o in the line AB (fig. 649.), describe the arc of the intrados aPf, and the arc of the extrados AQB: divide each of these arcs into odd numbers of equal parts (for the arch stones in this example five), and draw the joints bg, ch, di, ek. For the plan of the arc of the intrados draw AR perpendicular to AB, and draw the line of slope or batter AS. In the arc of the intrados take any number of points bcd, &c. and draw the lines bb', cc', intersecting AR in the points 1, 2, &c. and meeting the line of batter AS in the points bc. Draw CD parallel to AB, and at any convenient distance from it draw aubcw perpendicular to CD, intersecting it in the points e, l, m, n, &c. Find the points b', c', d' in the straight lines bv, mw, nx, such that the distance of those points from the line ED may be respectively equal to the intervals 1b, 1c, &c. between the perpendicular AR and the line of batter AS, and draw the curve a' b' c' d' e' f', which will be the plan of the arc of the intrados. In the same manner the curve Eg'h'ikD may be described; which being done, the plan of the arc of the extrados will be obtained.

1972. To find the moulds of the soffites and beds. Draw any straight line HI in a separate place, and extend the arc of the intrados abcdef upon the line HI from H to I; divide it into the same number of parts that the arc aPf of the intrados is divided into (in this instance five), and mark the points of division l', m', n'. Transfer the distances ea', lb', mc' between the line CD and the plan of the arc of the intrados, to the perpendiculars n'a'', l'b'', m'c'', n'd'', c'e'', and through the points a'b''c''d''e''f'' draw a curve, which will be the development of the arc of the intrados. Produce the lines l'b'', m'c'', n'd'', to v', w', x'', and transfer the distances bv, c'w, d'x from the plan to the sofitte on the lines b'v'', c'w'', d'x''. Draw ga'', hb'', ic'', kd'' perpendicular to HI; transfer the distances g'a, h'b, i'c from the plan to the sofitte upon ga'', hb'', ic'', and join a'v'', b'w'', c'x'', which will complete the moulds of the joints.

1973. To make the drawings for an oblique arch by an abridged method. The following method is said to be abridged, because, by one very short operation the moulds of the soffites and joints are found within the plan of the arch ABDC (fig. 650.). Divide AB in E into two equal parts, and draw EF parallel to AG. From the point A draw AG perpendicular to AC; prolong DB to G; divide AC into two equal parts in the point H. From H, as a centre, describe the arc AFG, which divide into voussoirs, and draw the joints from the centre H. Draw lines from each sofitte parallel to EF, and below the line CD; the moulds for the soffites are comprised between the parallels of the key, and those of the joints are traced on the sides of the plan, as follows:—

1974. To find the moulds of the soffites. Through the point Q draw QN parallel to GH. To find on RS the point N, through the point K draw KL also parallel to GH. To find on QT the point M, and on RS the point L, draw the front line of the second sofitte

Fig. 649.

MN, and the front line of the first IL. The back of this sheeting sofit is found by the same operation below the plan. The mould of the key is formed by two lines RS, QT, and the front and back lines of the plan AB, CD; the two moulds of the soffites NMTS and LIXV serve to trace the two stones on each side, observing only that the lower arrises of the sofit on the side AC become those of the top on the side BD; or that the under arris of one side may be that on the other side by reversing the mould, which will have the same effect.

1975. *To find the moulds of the beds or joints.* Prolong NQ to meet DG, to find the point P, and through it and the point E draw the front of the second joint P2; prolong LM to GD to find O, through which and the point E draw the front of the joint O3. Proceed in the same manner to find the backs of the other joints, which are sufficient also to trace the stones by reversing them. It is not absolutely necessary to cut out the moulds of the soffites and joints, but the angles may be taken by bevels and applied to stones. The heads are prepared, as usual, with the moulds of the heads of the straight arch. It must be observed, that in this arch the face or front differs from a straight arch, being formed by different sections of a cylinder.

1976. *To find the moulds for an oblique arch, whereof the front slopes and the rear are perpendicular to the axis.* Let A'B'GHI (fig.

651.) be the plan of the impost. From the point  $a'$ , as a centre, describe the arcs ACB, DRI, which divide into five or more equal parts for the arch stones. Draw the joint lines from the centre, and the perpendiculars from the joints below the line AB. From the summits of the perpendiculars, draw lines parallel to AB, to terminate in the perpendiculars DF. From the point D, as a centre, describe arcs from the points which terminate in DF, to meet the line of slope DE in the points  $m, l, k, E$ . Draw the lines  $mr, l, kt$ , EF parallel to AB, meeting the perpendicular DF in the points  $rstF$ ; transfer the distances  $rm, tk, uP$  from  $n$  to  $b'$ , from  $o$  to  $c'$ , from  $a'$  to  $s'$ , and through the points  $A'b'c'd'e'B'$  draw the curve. Find the extrados or outer line  $Dfyhi$  in a manner similar to that in which the inner curve has been found. Draw the joints  $b'f, c'g, d'h, e'i$ . Prolong AH and BG to K and L, and draw the lines  $b'b, cc, d'd$  parallel to AK.

1977. *To make the straight arches.* Draw KL perpendicular to AK, and produce KL to  $f$  and  $g$ . Transfer the distances between the points  $m, l, k, D$ , and the line QD to the ordinates of the lower arc from  $b$  to  $v$ , from  $c$  to  $w$ , from  $d$  to  $x$ , and from  $Q$  to  $Y$ , and draw the curve  $KwxyL$ . Also find the outer curve in the same manner, and draw VT at right angles to AH.

1978. *To find the moulds of the soffites.* Draw the line WX (fig. 652.) in any convenient surface, and lay the breadths of sofit, not from the arc ACB as before, but from those of the right arc  $KwxyL$ , that is, transfer the distances  $Kr, rv, wx, xy, yL$  to the line WX upon  $Wa, aa, \beta b, gy\delta d$ , and  $\delta X$ . Through the points  $WabydX$ , draw the lines  $ny, ei, fh, gl, hm, \delta z$ , perpendicular to

Fig. 650.

Fig. 651.

Fig. 652.

WX. Transfer the distances  $1A, 2b', 3c', 4d', 6B$  upon the perpendiculars to WX. From  $Wn$ , from  $a$  to  $e$ , from  $b$  to  $f$ , from  $c$  to  $g$ , from  $d$  to  $h$ , and from  $X$  to  $v$ , and join  $ne, ef, fg, gh, hv$ . In the same manner draw the line  $yiklmz$ , which will complete the soffites.

1979. *To find the moulds of the joints.* Transfer the distances  $r\beta, w\gamma, x\delta, y\epsilon$ , on the line  $XW$  from  $a$  to  $\alpha$ , from  $b$  to  $\beta$ , from  $c$  to  $\gamma$ , and from  $d$  to  $\delta$ , and through the points  $\alpha, \beta, \gamma, \delta$  draw the lines  $ny, os, Pt, \delta u$  perpendicular to WX. Find the points  $n, o, p, q$ , as also  $r, s, t, u$ , as in the preceding examples; then the moulds of the joints will be  $eirn, fkso, htig, h\delta ug$ . It must be observed that the boundaries, or extrados and intrados, DRI, ACB of the ring of the arch, do not stand in a plane perpendicular to the plan, but are supposed to be the lines which are drawn on the wall itself; and this is the reason why arcs are described between the perpendiculars DF and the line of slope DE. It must also be observed, that the voussoirs of this arch must be cut by the moulds of the heads of the straight arch, and the moulds of the sofitte must be applied on the voussoirs before the sofitte is hollowed. Thus, let the first voussoir on the right hand be cut by the head mould on that face of the stone intended for the sofitte; apply the first sofitte mould, and its upper bed the first joint mould, and on its under bed the plan of the impost. Then cut the two heads according to these moulds, and hollow the sofitte square to its arrisses, using for this purpose the curved bevel.

1980. *To find the moulds for executing a semicircular-headed arch in a mass of masonry, of which one of its faces is a battering plane upon an oblique plan, and the other opposite face a portion of a cylindric surface.* Describe the intrados and extrados of the elevation; draw the joints and describe the plan  $a'b'c'd'e'f'$  of the intrados (fig. 653.), and the plan  $Eg'h'i'k'D$  of the extrados. Draw  $BR$  perpendicular to  $AB$ , and draw  $BS'$ , the portion of the cylindric surface. From the arc  $BS'$  draw the line  $a'l'm'n'o'f'$  of the intrados upon the line  $TU$ , and the plan  $Tp'q'r's'U$  of the extrados in the same manner from the arc  $BS$ , as the plan of the plane face was drawn from the line of slope  $AS$ .

Fig. 653.

1981. *To find the plan of any joint,* as that for the line or joint  $ch$  in the elevation. Bisect  $ch$  in  $v$ , draw  $cm', rw'$ , and  $hq'$  perpendicular to  $AB$ , intersecting the line  $VD$  in the points  $quc$ . From the points  $cvh$ , in the joint  $ch$ , draw  $cc, vv, hh$ , meeting the line  $AS$  in the points  $cvh$ , and intersecting the line  $AR$  in the points  $1, 3, 2$  by three intervals,  $1c, 3r, 2h$ . Find the places  $hvc$  of the three points  $hvc$  on the elevation. In the same manner find the places  $q'w'm'$  of the three corresponding points; then will  $c'v'h'q'w'm'$  be the plan of the joint required. The plans of the other joints will be found in the same manner.

1982. *To find the joint mould itself.* Draw the line  $HI$  (fig. 654.) equal in length to the development of the intrados, and let  $Hc$  be the development of the arc  $ac$ ; draw  $cm''$  perpendicular to  $HI$ . Draw any line  $WX$  in the plan parallel to  $VD$ , intersecting the lines  $c'm', v'w', h'q'$ , in the points  $1, 2, 3$ . Draw  $W'X'$  in the development or sofitte parallel to  $HI$ , and at the same distance from  $HI$  that  $WX$  is from  $VD$  in the plan, and let  $WX$  intersect the line  $c'm''$  in  $1$ . Make the distances  $1-2, 2-3$  respectively equal to  $cv, vh$ , in the joint  $ch$  in the elevation, and through the points  $1, 2, 3$ , just found, draw  $VW, h'w'q''$ , parallel to  $C'm''$ . From the plan transfer the distances  $2v', 2w', 3h', 3q''$  to the sofitte from  $2$  to  $V$ , and from  $2$  to  $W$ ; also from  $3h''$  and from  $3$  to  $q$  the points  $crp''$  will be in a straight line, because they correspond to the straight face of the wall, and the points  $m'', w, q''$  will be in a curve, because they correspond to the cylindric surface. Draw, therefore, the straight line  $c'h''$ , and draw the curve line  $m''wq''$ , which will be a portion of an ellipsis, differing in its curvature but in a very small degree from that of a circle drawn through the same three points. However, if more exactness be required, we may find as

Fig. 654.

many points in the joints of the surface of the wall and in the cylindric surface as we please; then  $c'm'p'h'$  is the joint required, which serves for the upper and under beds of the two stones that unite together in that joint.

1983. Find all the other joint moulds  $b''l'p'g'$ ,  $d'n'v't'$ ,  $e'o's'k''$ , in the same manner, and find the points  $a''f''$  in the development. Through the points  $a''b''c''d''e''f''$  draw a curve line by hand, or by a ruler bent to the points, and this will be the front curve of the sofitte. Find the points  $k'p'$  in the development corresponding to the points  $a'$  and  $f$  on the plan, and through the points corresponding to the points  $a'$  and  $f$  on the plan, and the points  $k''l''m''n''o''p''$ , draw another curve, which will be the development of the other side of the sofitte. The developments of each of the parts of the sofitte and of the two adjacent joint moulds give the three moulds for working one stone and the adjacent joints of the stone on each side of it. The angle which each of these joints makes with the sofitte is found by making a bevel with one of its edges, circular for the intrados of the arc of the elevation, and the other to coincide with the joint line adjacent.

1984. To find the moulds for executing a gateway in the quoin of a sloping wall. Let ABCD (fig. 655.) be the plan of the angle in which the arch is to be constructed, whereof AB is the span. Draw the centre line EL, to which draw the perpendicular FG. Prolong the line CA to F, and DB to G; then from the point L, as a centre, describe the sofitte FHG and its extrados. Divide these arcs into equal parts for the arch stones, and from the divisions let fall perpendiculars, and also from the middle of the sofittes to EC, ED. From the summits of the perpendiculars draw lines parallel to FG terminated by the lines of slope. Set off the slope at the different heights  $a_1$ ,  $a_2$ ,  $a_3$ ,  $a_4$  respectively at right angles to the lines on the plan, on  $d_1$ ,  $b_2$ ,  $d_3$ ,  $b_4$ , K5; also on the opposite side lay  $a_2$ ,  $a_4$  on  $d_2$ ,  $b_4$ ; then on one side draw the curve  $AbbK$ , and on the other, to abridge the work, join  $Bb$ ,  $bb$ ,  $bK$ . Again, for the outer curve, or extrados, set off  $c_1$ ,  $c_2$ ,  $cG$  on  $d_1$ ,  $d_2$ , N3. On both sides draw the curve  $MddO$  on the one side, and to abridge the labour, draw the straight lines  $Od$ ,  $dd$ ,  $dN$ .

1985. To find the moulds of the sofittes.

Draw the line PQ (fig. 656.), on which lay the arc of the sofitte FHG in the usual manner, making the points 1, 2, 3, which correspond to the points dividing such arc into equal parts; then on the lines of the sofitte lay the distances FA,  $f_b$ ,  $g_b$ ,  $h_b$ , LK, on PR,  $1_k$ ,  $2_l$ ,  $3_m$ ,  $4_m$ , QS, and trace the front curve of the sofitte  $RklmnS$ . Also repeat the same on the other side where there is only a straight line drawn from one sofitte curve to another.

1986. To find the back curve of the sofitte. Lay the distances  $eo$ ,  $fp$ ,  $gq$ ,  $kr$ , LE on PT,  $1_o$ ,  $2_t$ ,  $3_u$ ,  $4_v$ , QU, and trace the curve TotuvU.

1987. To find the moulds of the beds or joints. The sofitte lines to which the beds belong are  $2t$  and  $4v$ . Draw the straight lines  $eb$ ,  $fd$  parallel to QU, respectively distant from  $2t$ ,  $4v$  by the breadth GI of the joint, and let the lines  $be$ ,  $fd$  meet PQ in  $e$  and  $f$ ; make  $ea$  equal to  $gd$ , and  $ab$  equal to  $dw$ , and join  $al$ ,  $bt$ ; make  $fc$  equal to  $hd$ , and  $cd$  equal to  $dx$ , and join  $nc$ ,  $vd$ . To trace the stones by moulds, prepare the voussoirs with the head of the moulds of the straight arch FHG. The sofitte should be hollowed in each voussoir by its particular mould: the rest is done as usual; but it must be observed, that if the sofitte moulds are made with straight lines in front and near the sofitte, it must not be hollowed till the last. The voussoirs may be worked by bevels, preparing the stones by the plans ACVM, BDWO, as for common imposts. Although the arch in each front be not absolutely necessary here, we shall give the method of constructing it. Let the line  $mn$  be drawn apart, on which lay the distances L5, L4, L2, LA on the lines  $ns$ ,  $nq$ ,  $no$ ,  $nm$  square to  $mn$ . Draw the perpendiculars  $op$ ,  $qr$ ,  $st$ , on which lay the heights of the joints of the straight arch taken on the line of slope; that is, lay I2, on  $op$ , I4 on  $qr$ , I5 on  $st$ , and

Fig. 655.

Fig. 656.

draw the line  $nt$ , which is the slope. Then draw the curve  $mprt$ , and from the point  $n$  draw the joint lines  $pv$  and  $rx$ . The centre of this gate is represented (in the upper part of the diagram) with voussoirs, and the keystone placed behind to show the mitre of the centre. The sofitte moulds serve for curving the ends of the stone where the intrados meets the surface of the two walls. It must, however, be observed, that, previous to the application of the sofitte mould, the concave surface of the intrados must be formed by a mould with a convex edge, and then the sofitte mould or moulds of developement must be bent into the hollow, so that the two parallel edges may coincide with the corresponding edges of the stone. The angles which the intrados makes with the joints are taken from the elevation of the face of the arch. This elevation is no more than a section of the arch perpendicular to the axis of the cylinder which forms the intrados.

1988. To construct a semicircular-headed arch in a round tower or circular wall. Let  $ABDC$  (fig. 657.) be the plan of the tower. Bisect the arc  $AB$ , and through the point of bisection draw  $EF$  parallel to the jamb line  $AC$  or  $BD$ . Through any point  $a$  in  $EF$  draw  $GH$  perpendicular to  $EF$ . Produce the lines  $CA$  and  $DB$  to meet  $GH$  in the points  $G$ ,  $H$ , and  $GH$  will be bisected in  $a$ . From  $a$ , as a centre, and with the radius  $aG$  or  $aH$ , describe the semicircular arc  $GfH$ . Also describe the arc of the extrados and divide the arcs each into five equal parts, and let fall the perpendiculars of the joint lines, and those of the middles of the sofitte curves to the inside circular line  $CED$  of the tower. Having extended the arcs of the intrados curve on the line  $IK$ , and having drawn the lines of the sofittes and those in the middle of each sheet as before directed, lay off the distances between the right line  $GH$  and the circular outside line  $AbB$ , viz.  $GA$  on  $IX$  and on  $KZ$ ,  $ed$  on  $ef$ ,  $Vg$  on  $hi$ ,  $Sk$  on  $lm$ ,  $Mn$  on  $op$ ,  $ab$  on  $qr$ ; then trace the front curve on the sofitte  $XrZ$ . To find the rear curve, lay  $GC$  on  $IY$ ,  $cC$  on  $eS$ , &c., by which the rear curve will be obtained.

Fig. 657.

1989. We do not consider it necessary to pursue the construction of the moulds, the operations being very similar to those already given in the previous examples.

1990. To find the moulds for an oblique semicircular arch in a circular tower. The construction of this differs from the preceding only in the bevel or obliquity of the tower; hence it requires no particular description; only observing, that the bevel causes the mould to be longer on one side than on the other (see fig. 658.), as is evident from the plan; therefore the distances taken between the right line  $AB$  and the circular line of the tower  $CDE$ , being unequal, must be transposed each on its particular line of the mould and joint to which it corresponds in the sofitte, that is, the distance  $AC$  must be laid on  $FG$ ,  $BE$  on  $HI$ , and so of the rest. To work the stones, dress the beds, then apply the proper moulds and cut the head and tail circular as before. Trace the breadth of the sofitte on the upper bed, then hollow the sofitte, and cut the joints by the bevel.

Fig. 658.

1991. To construct an oblique arch in a round sloping tower intersecting a semicircular arch within it. This is nearly the same as the two preceding cases. On one side draw the line of slope (fig. 659.)  $AB$ , and on the other the arc  $CD$ . Draw parallels from the divisions of the sofittes and their middles, as in the figure, in order to cut the line of slope and arc. To work for the slope, set off all the retreats comprised between the perpendiculars  $AH$  and the line of slope  $AB$  on the perpendiculars of the sofitte, square to the front line of the tower  $F 19 G$ , as follows: Transfer the retreat 9—10 on 19—20 by placing the compasses so that the line 19—20 would pass through the centre of the tower, and the point 20 fall on the centre of the gate  $O$ —75, and 7—8 on 17—18, and on 21—22 in the same manner (only terminated by the lines

from the soffit instead of the centre line of the arch), set also 5—6 on 15—16, and on 23—24, 3—4 on 13—14 and on 25—26, and lastly 1—2 on 11—12 and on 27—28, and through these points trace the soffit 28—20—11. The extrados is found in like manner, and the middles of the joints 47, 49, 53; which done, draw the plan of the joints 14—47—35, 18—19—37, 22—51—39, and 26—53—41.

1992. *To find the curve of the plan which terminates the tails of the moulds.* Set the projections of the buttress of the semicircular arc at right angles to the inside line of the tower; viz. 64—65 on 74—75; 62—63 on 72—73 and on 76—77; 60—61 on 70—71, and on 78—79, 58—59 on 68—69, and on 80—81; 56—57 on 66—67 and on 82—83; then trace by hand the curve 83—75—66. The curves of the extrados and joints are found in the same manner.

1993. *To find the moulds of the soffit.* Draw the line of direction 94—84 (*fig. 660*) as before, below which set off the distances I—11 or 84—85, K—12 on 86—87, L—14 on 88—89, M—16 on 90—91, N—18 on 92—93, O—20 on 94—95, and then trace the front of the soffit moulds 85—95—99. To find the rear, set I—66 on 84—33, K—67 on 86—36, L—69 on 88—100, M—71 on 90—98, N—73 on 92—97, O—75 on 94—96, and trace the rear curve of the mould 101—96—33.

1994. *To find the moulds of the joints.* Transfer P—19 on 31—54, Q—37 on 32—48, I—47 on 42—52, R—35 on 43—40, and through these points trace the front joint or bed moulds 93—54—48, 89—92—40. To find the rear, make 31—50 equal to PV, 32—38 equal to QX, 42—46 equal to IT, and 43—34 equal to RS; which done, trace the curve lines 97—50—38 and 100—46—34. The two other joints are found by the same method. We do not consider it necessary further to multiply examples of the kind here given: the latter sort, especially, rarely occur in practice; and if they should, all that will be necessary to master the operations will be the application of a little thought and study.

1995. III. OF DOME VAULTING. In whatever direction a hemispherical dome is cut, the section A is always the same. B represents one half (see *fig. 661.*) of the same in the plane of projection. The construction is sometimes such that the plan is only a semicircle, as B, as in the termination of the choir of a church: in which case the French call it a *cul-de-four*; with us it is called a semi-dome.

1996. Through the extremities of the joints, and through the middle of each soffit of the section A, let fall on the line *ab*, perpendiculars, whereof all the distances *dc* from the centre *c* will be the radii of the arcs, which will serve for the developement of the soffits, of the joints, and for the construction of the arch stones. The method which follows, though it will not perhaps give the soffits and joints strictly accurate, will do so sufficiently for all practical purposes. Upon the developement C make SC equal to the arc MDGC, then set out to the right of the points of division the parts ST equal to *st* on the plan B; then raise through the points T upon the line SC perpendiculars equal

Fig. 659.

Fig. 660.

Fig. 661.

to the correspondents *e*, *t*, *d* of the plan B, and draw the curve ESD through the points so found.

1997. The soffites are terminated by four curves, whereas the joints have two right sides, as DI, EI, and DO, EO, and two curved sides, as II, DE, and OO, DE; the widths DI, DO of the joints are equal to DI, GE of the section; in one direction they are curved only one way, but as respects their soffites they are so in every way. The heights of the voussoirs are given by the section A, their bases on the plan B. Thus G, I, in the voussoir next the keystone, being the most opposite points, the base of it on the plan will be comprised between the two arcs *dte*, which answer to the perpendiculars let fall from G and I. The base of the first voussoir, according to the first method, will be equal to the surface comprised between the arc *aof* and the arc *dse*, which answers to the perpendicular let fall from the point D.

1998. EF and GH are the diameters of the upper and lower bases of a truncated cone, whose lower surface is hollowed out spherically. After working the voussoirs, so as to make their bases such as we have just indicated, they must be worked to sofit moulds for giving them the hemispherical form of the section; after which the angles of the moulds are joined by arcs parallel to the arrisses of each stone, or by applying a general mould of the form of the section, that is, circular, of the radius of the dome.

1999. For the pendentives formed in an hemispherical dome. The piers D and E are supposed those of half the dome pierced by the pendentives. If we suppose the face or elevation B (*fig. 662.*) to make one quarter of a revolution about the point A, we obtain the elevations B and C. Through the points of division on the elevation C draw to the arc AD right lines perpendicular to CA. On the extremities of these lines upon CA, and from C, as centre, describe arcs in the plan F, by which the plan of the projection on F is obtained, whose intersections with the right lines drawn from B will give the joints and faces for the level beds. The lines HF, FE, ED are right lines. The spaces GAEF, FHIK are pieces of cylindrical vaulting, so that the only difficulty is in joining to each of their voussoirs their correspondent parts in ELMHFE.

2000. The elevation B gives the height of the voussoirs; their bases, as seen in the preceding example, will be OPQRNO, GSTUVKFG. The length of the keystone will be XY, and *a*—A will be half its width.

2001. The part FQR is the plan of the springing stones of the pendentive in the elevation A. The remaining parts of the construction are sufficiently shown by the lines of the diagram, which will be understood by the student if he has previously made himself acquainted with the previous portions of this section.

2002. We should willingly have prolonged this part of our labours, if space had permitted us to do so without sacrificing other and important objects. If the subject be one in which more than the ordinary practice of the architect is called upon to put into execution, we refer him to Simonin, *Coupe des Pierres*, Paris, 1792, and Rondelet's *Art de Bâtir*, which we have used with much freedom, and in which many more interesting details will be found than we have thought it absolutely necessary here to introduce, though we believe we have left no important point in masonry untouched. We cannot close this section without paying our tribute of respect to the masons of this country, who are among the most intelligent of the operative builders employed in it. A very great portion of them are from the north of the island, and possess an astuteness and intelligence which far exceeds that of the other classes of artisans. We must not, however, altogether do this at the expense of those employed in carpentry, which will form the subject of our next section, among whom there will be found much skill and intelligence, when the architect takes the proper means of drawing it out; and we here advise him never to be ashamed of such means.

Fig. 662.

## SECT. IV.

## PRACTICAL CARPENTRY.

2003. Carpentry is the science of framing or letting into each other an assemblage of pieces of timber, as are those of a roof, floor, centre, &c. It is distinguished from joinery in being effected solely by the use of the *axe*, the *adze*, the *saw*, and the *chisel*, which are the carpenter's tools; whereas joinery requires the use of the plane.

2004. Though necessarily of high antiquity, the very scanty information which Pliny and Vitruvius have left us on the subject would merely show that the science was known by the ancients. The roofs of Egypt present us with no more than flat coverings of massy stone; a pediment roof, therefore, would seem to have been among the first efforts of constructive carpentry; and upon the pitch which this, then and since, has received in different countries, we shall hereafter have to speak. The Greeks appear to have used carpentry in the construction of their floors and some other purposes; but in a country abounding with stone and marble, it is not likely that wood was much used in the interiors of their buildings, unless where lightness, as in doors, for instance, required its employment. With the Romans it was much more commonly used; and from all that can be gathered, we may consider them as the fathers of the science.

2005. Among the moderns it has been very successfully cultivated; and, with very few exceptions, we may almost assert that the works of Palladio, Serlio, Delorme, Sir Christopher Wren, Perronet, and a few others, exhibit specimens which have scarcely been surpassed in later times, notwithstanding the scientific form it has assumed in the present age.

2006. To the mechanical principles of carpentry we have, in Chap. I. Sect. XI. of this Book, directed the attention of the student; and to the section now under our pen we should have added the heading *Descriptive to Practical Carpentry*, but that much of what could have been said on that head has already been anticipated in our section on Descriptive Geometry. Hence, in what follows, that which comes under such predicament will be only given in particular cases, for the purpose of saving time and trouble to the reader in the application of its principles to them. We must, here, also remind the reader, that under the section of Mechanical Carpentry have been described the different sorts of timber used for building purposes, their strengths, and the strains to which they are subject and which they are capable of resisting; and that therefore this section is confined simply to putting pieces of timber together, so as to form the assemblage of timbers under which we have commenced by defining the science. To do that properly requires great skill and much thought. Considerable waste, and consequent expense to the architect's employer, result from that ignorance which assigns to the scantlings of timber larger dimensions than are absolutely necessary for the office of each piece; insufficient scantlings will bring the architect into trouble and responsibility; and the improper connection of the pieces will be equally ruinous to his reputation. The principles of practical carpentry are, nevertheless, simple; and though to form new combinations and hazard bold and untried experiments in practice will require all the skill and science of a talented artist, the ordinary routine of carpentering is to be learnt by a little application and a due exercise of common sense.

2007. After these observations, we must introduce the student to the first operation which in practice may arise. It is not every where that timber can be obtained in sufficient length to stretch across the void he has to cover; and it will in such cases be necessary for him to know how one piece of timber may be so joined to another, for the purpose of lengthening it, that the two pieces, when joined, may be as nearly as possible equal in strength to one whole piece of timber of the same dimensions and length. This operation is of great service to the builder, and is technically called *scarfing*. To perform it, the joints are indented, and bolts are passed through the pieces within the length of the indents, such bolts being confined above and below by means of nuts and screws. In

fig. 663. four ways are exhibited of accomplishing the object in question. A and B are the methods usually employed for joining together plates, lintels, and ties, in which bolts

Fig. 663.

are rarely necessary; but if such a method is used for scarfing beams, bolts must be employed. The stronger forms, which only should be used for beams, shown in C and D, are not only in that respect such as should, on that account, be used for beams, but are executed without loss of length in the pieces of timber. The length of the joints of the scarfing may be increased at pleasure; the diagrams are merely given to show the mode of doing what was required. With fir, however, when bolts are used, about four times

the depth of the timber is a usual length for a scarf. Scarfing requires great accuracy in execution; for if the indents do not bear equally, the greater part of the strength will be lost: hence it is improper to use very complicated forms for the indents.

2008. Pieces of timber are framed into and joined to one another, by the aid of *mortices* and *tenons*, and by iron straps and bolts; and on the proper placing of these depends the soundness of the work. If a piece of framing is to stand perpendicularly, as in the case of partitions, without pressure from either side, the mortice and tenon should be in the centre of the wood. But in the case of framing floors, in which the pressure is on the upper surface, and entirely on one side, the mortices and tenons ought to be nearest the side on which the pressure is, by which the timber will not be so much weakened; and hence it is the constant practice to cut the mortices and tenons as in *figs. 664, 665*. By the method shown in the last-named figure, the tenon obtains more strength from an additional bearing below, which is further increased by the inclined butment above, called a *tusk*.

2009. The method of framing wall plates together at an angle, for the reception of the hip rafter on the *dragon beam*, and the angle ties for retaining the wall plates in their places, is shown in *fig. 666*, wherein AB is the mortice cut for the tenon of the hip rafter

Fig. 666.

Fig. 667.

Fig. 668.

Fig. 664.

Fig. 665.

Fig. 669.

shown in *fig. 667*. *Fig. 668* is one of the wall plates, showing the halving to receive the other plate, and the cutting necessary for dovetailing the angular tie. *Fig. 669* shows the method of cutting the mortices and tenons of principal and hip rafters; another method being given in *fig. 670*, and to be preferred where a greater resistance to thrust is sought, because by it a double *butting* is obtained on the tie beam. Inasmuch, however, as in this last case the beam is cut across the grain to receive the rafter, the part left standing to receive the heel of the rafter may be easily split away; to obviate which, the socket may be cut, as at A, parallel to the grain of the wood. *cd* is the iron strap for securing the rafter's foot to the tie beam, and keeping it in its place. A plan of the upper part of the tie beam is given at B, showing the socket and mortice of the section A in the last figure. C exhibits the mode in which a king-post is strapped to a tie beam, with the *struts* and *joggles*.

2010. The most approved method of forming butments (*fig. 671*.) for the *struts* or *braces*, *aa*, which are joggled into the king-post, is to make their ends, which act against the joggle, perpendicular to the sides of the brace; they will thus be kept firmly on their butments, and have no tendency to slide. C is a section of the king-post and tie beam, showing the mode of wedging and tightening the strap, with a single wedge, in order to draw the tie beam close to the king-post. D is a section of the same parts to a larger scale, and with the introduction of a double wedge, which is easier to drive than a single one, because there is less action upon the cross grain of the wood.

2011. Straps in carpentry should be sparingly used. Professor Robison has very properly observed, that "a skilful carpenter never employs many straps, considering them as auxiliaries foreign to his art." The most important uses of them are, that of suspending the tie beam to the king-post, and of securing the feet of the principal rafters to the tie beams in roofs.

2012. Bolts are sometimes used for the last-named office, with *washers* and heads and screw nuts, in which case the washers, nuts, and heads should be well painted, though

Fig. 670.

Fig. 671.

even then they are liable to rust. Wherever the iron work used for securing a system of framing is exposed to the humidity of the atmosphere, it should be rendered durable by frequent painting. Price (*British Carpenter*, 1759) observes thus: "There is one particular that had liked to have escaped my notice, concerning the placing of iron straps on any truss, thereby meaning to help its strength, which is by turning the end square (as shown at E, *fig. 671.*). This method embraces the timber in such a manner, to make it like a dovetail, *which cannot draw from its place*; another observation is, to bolt on your straps with square bolts, for this reason: if you use a round bolt, it must follow the auger, and cannot be helped; by this helping the auger-hole, that is, taking off the corners of the wood, you may draw a strap exceeding close, and at the same time it embraces the grain of the wood in a much firmer manner than a round pin can possibly do." The example given by Price, however, for turning square the strap, is injurious to the rafter, which must be partially cut to admit of it.

## FLOORS.

2013. The assemblage of timbers in a building, used for supporting the flooring boards and ceiling of a room, is, in carpentry, called *naked flooring*, whereof there are three different sorts, viz. *single flooring*, *double flooring*, and *double-framed flooring*. But before entering on the particulars of either of the sorts, we will make some general observations on the construction of floors, which require the architect's attention. **FIRST**, the wall plates, that is, the timbers which lie on the walls to receive the ends of the girders or joists, should be sufficiently strong and of sufficient length to throw the weight upon the piers. **SECONDLY**, if it can be avoided, girders should not lie with their ends over openings, as doors or windows; but when they do, the strength of the wall plates must be increased. To avoid the occurrence in question, it was formerly very much the practice in this country, and indeed is still partially so, to lay girders obliquely across rooms, so as to avoid openings and chimneys, the latter whereof must indeed be always attended to. **THIRDLY**, Wall plates and templets must be proportionately larger as their length and the weight of the floor increases. Their scantlings will, in this respect, vary to  $4\frac{1}{2}$  by 3 inches, up to  $7\frac{1}{2}$  by 5 inches. **FOURTHLY**, The timbers should always be kept rather higher, say half to three quarters of an inch higher, in the middle than at the sides of a room, when first framed, so that the natural shrinking and the settlement which occurs in all buildings, may not ultimately appear after the building is finished. Lastly, when the ends of joists or girders are supported by external walls whose height is great, the middles of such timbers ought not at first to rest upon any partition wall that does not rise higher than the floor, but a space should, says Vitruvius (lib. 7. c. 1.), be rather left between them, though, when all has settled, they may be brought to a bearing upon it. Neglect of this precaution will induce unequal settlements, and, besides causing the floor to be thrown out of a level, will most probably fracture the corners of the rooms below.

2014. **SINGLE FLOORING** is constructed with only one series of joists (as shown in *fig. 672.*). In this way of framing a floor, if a girder is used, it should be laid as nearly as possible over the centre of the apartment. A *single floor* containing the same quantity of timber as a double floor is much stronger; but the ceiling of the former is liable to crack, and cannot be got to so good a surface when finished. Hence, where the bearings are long, it is much better to use double flooring.

Fig. 672.

2015. The scantlings of fir joists for single flooring are exhibited in the subjoined table, and are founded on our own practice. The weight of a square varies from 11 to 18 cwt.

Length in Feet.	Width in Inches.	Depth in Inches.
6	2	6
8	$2\frac{1}{2}$	7
10	$2\frac{1}{2}$	$7\frac{1}{2}$
12	$2\frac{1}{2}$	8
14	$2\frac{1}{2}$	9
18	$2\frac{1}{2}$	12
20	3	12

These scantlings may be varied if wanted, according to the laws laid down in the section on Mechanical Carpentry. (1622. *et seq.*)

2016. In *fig. 672.* AAA are the joists, and B the floor boards. The laths for the ceiling are nailed to the under side of the joists AAA.

2017. In most floors, on account of the intervention of flues, chimney openings, and occasionally other causes, it will so happen that the ends of the joists cannot have a bearing on the wall. In such cases a piece of timber called a *trimmer* is framed into two of the nearest joists (then called *trimming joists*) that have a bearing on the wall. Into the trimmer, which is parallel to the wall, the ends of the joists thus intercepted from tailing into the wall are mortised. The operation is called *trimming*. The scantlings of trimmers and trimming joists may be the same as those hereafter given for binding joists; or if to the width of the common joists an eighth of an inch be added for each joist supported by the trimmer, the depth being the same, the scantling will generally be sufficient.

2018. When the bearing of a single joist floor exceeds 8 feet, a row of strutting pieces should be introduced between the joists, by which they will be prevented from horizontal twisting, and the floor will be stiffened. If the bearing be more than 12 feet, two rows of stiffening pieces or struts should be introduced, and so on for each increase of 4 feet in bearing. They should be put in, in continued rows, and be well fitted. Beyond a bearing of 15 feet it is not advisable to use single flooring, neither ought it in any case to be used where it is required to prevent the passage of sound.

2019. A *double floor* consists in its thickness of three tiers of timbers, which are called *binding joists* (these perform the office of girders), *bridging joists*, and *ceiling joists*. From an inspection of fig.

673. the construction will be easily understood. AA are the binding joists, which are the principal support of the floor on the upper side, whereof BB, the bridging joists are notched; which is the best method,

Fig. 673.

though sometimes they are framed between with *chased mortises*. The binders, of course, run from wall to wall; and as for carrying the floor, the bridging joists, as their name imports, are *bridged* on to them; so the lower tier of timbers, called the *ceiling joists*, are either notched to them, or are what is called *pulley mortised* into them; that is, a chase is cut in the binder long enough to allow of the tenons of the ceiling joists being obliquely introduced into them and driven up to their places. The scantlings of timbers used in this method are the same as those for doubled-framed flooring, of which, indeed, it is but a species.

2020. The *double-framed floor* differs only from the last-named by the binding joists, instead of going from wall to wall, being framed into large pieces of timber called *girders* (as shown in fig. 674.), wherein A is the girder, B a binding joist, C a bridging joist, D a ceiling joist, E the pulley mortice for the ceiling joist D, and F is the floor.

Fig. 674.

The great advantages of this sort of flooring are, that it prevents the passage of sound between the stories, and enables the architect to make a solid ceiling.

2021. As in a double-framed floor the girders are the chief supports, it is exceedingly important that they should be sound and free from shakes. The distances between one girder and another, or the wall, should not exceed 10 feet, and their scantlings as in the following table:—

Girders of the length of 10 feet should be 9 inches deep, 7 inches wide.

12	—	10	8
14	—	11	9
16	—	12	10
18	—	12	11
20	—	13	11
22	—	14	12
24	—	15	12
26	—	16	12
28	—	16	13
30	—	16	14

Girders whose bearing exceeds 24 feet are difficult to be procured of sufficient depth, in which case an expedient is put in requisition to strengthen a less depth. The principles it involves will be explained under the head of Roofs, namely, those of *trussing* them, an operation which converts the girder within its own thickness into a piece of framework, for the purpose of preventing the bending, or as it is technically called, *sagging*, of the girder, which produces an injurious horizontal thrust on the walls. This operation is represented in *fig. 675.* in two different ways, the lower portion of the diagram representing the plan.

Fig. 675.

The girder is cut into two halves in the direction of its depth and length, between and into which the truss is inserted, as shown. It is better that the *truss posts* A, and *abutment pieces* B, should be of wrought iron; the *struts* C may be of oak, or some stiffer wood than the girder itself.

2022. We now return to the subject of binding joists, which ought not to be more than 6 feet apart. The depths, if necessary, for accommodating them to the thickness of the floor, may be varied from the following table by the rules already given under the section MECHANICAL CARPENTRY.

Binding joists of the length of 6 feet should be 6 inches deep, 4 inches wide.

8	—	7	4½
10	—	8	5
12	—	9	5½
14	—	10	6
16	—	11	6½
18	—	12	7
20	—	13	7½

The scantlings of bridging joists are similar to those already given for single flooring. These, as well as ceiling joists, whose scantlings are subjoined, should not be more than 12 inches apart, and they require to be scarcely thicker than is necessary to bear the nails of the laths fixed to them, for which 2 inches is quite sufficient.

Ceiling joists of the length of 4 feet should be 2½ inches deep, 1½ inch wide

6	—	3½	1½
8	—	4	2
10	—	5	2
12	—	5½	2½

The weight of a square of framed flooring with counter flooring varies from 22 to about 36 cwt.

2023. Though, perhaps, more curious than useful, we should not perform our duty to the student, were we to omit a method of constructing floors with short timbers, where long ones are not to be procured. Suppose it be required to floor the room ABCD (*fig. 676.*)

Fig. 676.

Fig. 677.

Let four joists, as in the figure, be mortised and tenoned at *abcd*, as there shown. Now it is evident that these joists will mutually support each other, for each is supported at one end by the wall, and at the other by the middle of the next joist. *Fig. 677.* shows another mode of accomplishing the same object; and many other forms would immediately suggest themselves to the experienced architect. The expedient is of ancient origin, inasmuch as our old master (so we delight to call him, notwithstanding the new lights that modern critics have found to guide them), Serlio, has described the expedient without any difference. In the fourth volume of *Rondelet (Art de Batir)*, an author to whom we are under infinite obligations, is described a floor executed at Amsterdam for a room 60 feet square, of exceedingly singular construction, inasmuch as it is without joists at all. Each side of the room is provided with very strong wall plates, whose angles are secured with iron straps, and are rebated to receive the flooring, which consists of three thicknesses of  $1\frac{1}{2}$  inch boards. Of these thicknesses, the first is laid diagonally across the opening, its ends resting on the rebates of the wall plates, and rising about  $2\frac{1}{2}$  inches towards the centre of the room. The next (second) thickness is laid diagonally at right angles to the first thickness, and the two are well nailed together. In the third thickness, the boards are laid down parallel to one of the sides of the room, and form the upper side of the floor, being, however, well nailed to those below. The whole of them are *grooved and tongued* together, forming a solid floor  $4\frac{1}{2}$  inches thick. In this example is an instance well worthy the study of the architect, as respects a scientific connection of parts, and the great advantage of a well-disposed bond. The floor in question is, in fact, a thin plate, well supported round the edges, the strengths of the plates being directly as the squares of their thicknesses, equally strong to bear a weight in the middle, whatever their bearing; though if the load be uniformly distributed, the strength will be inversely as the area of the space.

## PARTITIONS.

2024. The framework of timber used for dividing the internal parts of a house into rooms is called a *partition* or *quartered partition*. It is commonly lathed and plastered; when the spaces between the timbers or quarters are bricked up, it is called a *bricknogged partition*. The weight of a square of common partition is rarely less than from 13 to 18 cwt.; hence it becomes necessary to take care that partitions should not be set upon the floor, without taking due precaution to relieve it of the weight, either by struts, braces, or the formation of a truss in it. When a partition occurs in an upper story, under a strongly trussed roof, it may be often advantageously suspended from the roof, and its weight thus taken off from the floor below. If it have a solid bearing throughout its length, it requires nothing but struts between the quarters; but these are not absolutely required. The scantlings of the timbers of a quarter partition should vary according to the extent of bearing. Where that does not exceed 20 feet, 4 by 3 inches will be sufficient; and where it is as much as 40 feet, the quarters should not be under 6 by 4 inches, that is, supposing it to bear only its own weight. When it has to bear more, the scantling must, of course, be increased accordingly.

2025. *Fig. 678.* represents a design for a trussed partition, with a doorway in the centre

of it: in which *hh* is the head, and *AA* the sill; *dc*, *dc* the doorposts; *gg* the *intertie*, *Ad*, *Ad* the braces; *fd*, *fd* struts. *Fig. 679.* shows a method of trussing a partition in which the doors are at the sides. It is obvious that additional strength may also be gained, when wanted, by introducing a truss between the *intertie* and head of a partition. The angle of inclination of braces should be about  $40^\circ$  with the horizon.

## CARRIAGE OF STAIRS.

2026. The framed timbers which support the steps of a staircase are called the *carriage*. They generally consist of two pieces inclined to the pitch of the stairs, called the *rough strings*. When geometrical stairs consist of two alternate flights with a half-pace between them, the carriage of the half-pace is constructed with a beam parallel to the risers of the

steps, whose joists are framed into the beam for the support of the flooring. This beam is called the *apron piece*, and that which sustains the rough strings at the upper end is called the *pitching piece*. The joists of the half-pace are sometimes turned into the pitching piece, and sometimes bridge over it; but the steps of both flights are always supported by string pieces, as before. The upper ends of the string pieces at the landing rest upon an horizontal piece of timber, called, as above, an *apron piece*. The scantlings of the strings, of course, vary with the length of the inclined part. The depth given to joists of similar length will be more than sufficient

#### ROOFS.

2027. The first obvious consideration in constructing a roof is the slope to be given to it, which depends on the climate against which it is to serve as a protection, and on the materials to be employed in covering it. In hot countries, rain more rarely falls than in temperate ones; but when it comes, it descends very abundantly, which, added to the temperature of the air, makes it unnecessary to give a great slope to the roof, from which the water immediately runs, and the air dries it almost at the instant of the rain's cessation. In cold countries the rain is more searching, the air is more impregnated with moisture, and snow often lies for a long time on a roof; circumstances which require a greater proportional slope to be given to it. Again, roofs covered with lead, zinc, or copper do not require so great a slope as those covered with tiles or slates.

2028. Though among architects there does not appear to have been any fixed principle by which the slope should be determined, we find that in different climates suitable slopes have been adopted for similar materials. Thus in the southern parts of Europe we find the roofs very flat; whilst as we proceed into its northern parts the roof acquires a very considerable elevation. We shall here transfer to our pages the notice of this subject in the *Encyclopédie Methodique*, which we consider extremely important and interesting, inasmuch as it shows that necessity was the parent of beauty in the inclination of the roofs of the ancients; and in the times of the middle ages it had some influence even in the production and development of the lancet arch.

2029. The researches and observations made respecting the roofs of a great many ancient and modern buildings, situate in different countries, satisfy us that the slopes of roofs which have lasted best are always proportioned to the temperature of the climate. Before entering into the consideration of any law for determining the slope of a roof, it will be proper to comprehend the meaning of the word climate as here introduced, which we shall use in the same way as it is understood by geographers. According to them, the climates of the globe are comprised under belts or bands, of unequal size, parallel to the equator. Of them there are twenty-four between the equator and the polar circle, each of half an hour; that is, the length of the longest day of a place situated at the beginning of the climate is always shorter by half an hour than that of the place situated at the extremity of the same climate, or at the beginning of the succeeding one, proceeding from the equator towards the polar circle. This difference in the length of the day, caused by the greater or less obliquity of the tropic with the horizon, is one reason of the different degrees of temperature of countries corresponding to the different climates. We are not, however, to assume that the temperature will be exactly the same for all places under the same climate, since there are many circumstances which tend to make a place more or less damp, in which cases the slope of the roof should rather have a relation to a more northern spot. In the roofs of the Continent covered with the hollow tile, as in the south of France for instance, less slope is required than with the Roman tiles (see the word *TILE* in Glossary), which are in sections alternately flat and circular; and these, again, require less slope than the common plain tile or slate. From the observations that have been made, we find that the slope of roofs covered with hollow tile,  thus, of the south of France, should be after the

rate of three degrees for every climate, beginning from the equator and proceeding northward, and that when the Roman tile is used, an addition of three degrees should be made to such inclination; an addition of six degrees, if covered with slates; and of eight degrees, if covered with plain tiles. According to this law, the table which will be presently subjoined has been constructed, and a comparison of it with ancient buildings gives a remarkable corroboration of its value. Thus, at Athens, situated about the middle of the sixth climate, the slope of a pediment would be about  $16\frac{1}{2}^{\circ}$ ; and that of the Parthenon is actually about  $16^{\circ}$ ; that of the temple of Erectheus,  $15\frac{1}{2}^{\circ}$ ; of Theseus,  $15^{\circ}$ . In Rome, which is about one third of the way up the seventh climate, the Roman tile requires an inclination of  $22^{\circ}$ . The actual slope of the pediment of Septimius Severus is  $23^{\circ}$ ; those of the temples of Concord and Mars Ultor,  $23\frac{1}{2}^{\circ}$ ; of Fortuna Virilis and the Pantheon,  $24^{\circ}$ ; and, of more modern date, the slope of the roof of St. Paolo fuori le mura was  $23^{\circ}$ .

2030. We shall now give the reader the table above mentioned. The argument at the head of each column will render its further explanation unnecessary.

"There is no article," says Ware in his *Body of Architecture*, "in the whole compass of the architect's employment that is more important or more worthy of a distinct consideration than the roof. The great caution is," continues our author "that the roof be neither too massy nor too slight. Both extremes are to be avoided, for in architecture every extreme is to be shunned, but of the two the overweight of roof is more to be regarded than too much slightness. This part is intended not only to cover the building, but

to press upon the walls, and by that bearing to unite and hold all together. This it will not be massy enough to perform if too little timber be employed, so that the extreme is to be shunned. But in practice the great and common error is on the other side; and he will do the most acceptable service to his profession, who shall show how to retrench and execute the same roof with a smaller quantity of timber; he will by this take off an unnecessary load from the walls, and a large and useless expense to the owner."

2031. We shall now proceed to a popular view of the strains exerted by the timbers of roofs, referring the reader back to the section on Mechanical Carpentry for a more extended and scientific view of them. Suppose (*fig. 680.*), in the simplest form of roof, the rafters (shown by dotted lines) *AB*, *CB* to pitch upon the walls *Aa*, *Cc*. Let the rafters be supposed to be connected together at *B* as by a hinge, as also similarly connected with the walls at *A* and *C*. Now if the effective weight of the walls be not sufficient to resist the thrusts of the rafters, as respects the height, thickness, and situation of the centre of gravity of such walls, taken as solid masses and moveable on the points *X* and *Y*, it is manifest the rafters by their own gravity will descend, and the walls will spread and be thrown out of an upright, as in *ab* and *cd*, and the rafters will take the places shown in the figure. It has already (*Mechanical Carpentry*, 1633.) been shown that the horizontal thrust of a pair of rafters thus meeting each other, is proportional to the length of a line drawn perpendicularly from the rafter's foot until it intersects a vertical line drawn from its apex. As the roof therefore becomes flatter, the length of the perpendicular increases. Hence, if *AB* and *BC* be the rafters, and their weights be represented by their lengths, the weight or power of thrust exerted by the rafter *AB* in the direction of its length will be represented by *BO*, and the horizontal thrust by *AO*; *AO* being perpendicular to *AB*. To secure, then, the walls in their perpendicularity, which the thrust of the rafters tends to derange, a system of framing becomes necessary. Thus, in *fig. 681.*,

Fig. 680.

a beam *AC*, which from the office it performs of tying or confining the feet of the rafters is called a *tie beam*, is introduced across the opening, and into this beam the rafters are framed. If the tie is introduced above the level of the walls, it is called a *collar beam*, as *ac*. It is manifest that these beams exert their power in the same way that a string would, that is, that the principal strain which they have to perform is in the direction of their length, and hence, that for such especial purpose, if they be prevented from *sagging* or bending, a small size or scantling will be sufficient, for we have already seen that the cohesive power of timber is very great in the direction of its length. To take care that the tie beam thus introduced should be strained only in the direction for which it is used, we are now led to another expedient. The beam by its own gravity, especially in a large opening, would have a tendency to sag or bend in the middle, and the more so if its scantling be simply proportioned to its office of a tie. To prevent this a fresh tie is introduced called a *king-post* *DB* (*fig. 682.*), by which the beam is tied or slung up to the apex of the principal rafters; and this combination of a pair of rafters, a tie beam and a king-post, is called a *truss*, and is the most important of the assemblages which the carpenter produces. When the rafters are of such length that they would be liable of themselves to sag down, supports *aa* are introduced at the points where such failures would occur, and these supports are called *struts*, because their office is to strut up the rafter, which they should do as nearly as the case will admit in a direction perpendicular to the slope of the rafters.

Fig. 681.

Fig. 682.

2032. It is clear that out of this last case a fresh system of trusses may arise as in *fig. 683.*, for from those points procured by the struts against the rafters, new rods may

*fig. 683.*, for from those points procured by the struts against the rafters, new rods may

be slung for increasing the stiffness of the tie beam *ad infinitum* in theory, but not in practice, because the compressibility of the fibres of timber is considerable in lines perpendicular to their direction, and the contraction and expansion of metal places a limit to its use. This compression of timber deserves great attention on the part of the architect. We may lay down as a rule in respect to it that the more the weights or pressures act in the direction of the fibres, the less will be the compression.

2033. To exemplify this, *fig. 684.* shows in No. 1. the principal rafters of a roof butting in an ordinary roof, against the shoulders AB, CD of the kingpost, whose fibres, being vertical, are compressed by the pressure against it, on each side of the rafters, whereby they approach each other, causing the whole figure of the roof to suffer a change. For by the action of compression and its consequence the kingpost must descend, and with it, consequently, the tie beam which is slung up to it. To remedy the inconvenience in roofs constructed of fir, the kingpost is often made of oak, which is less compressible, a practice which should be observed in all roofs of consequence. But cast iron kingposts are the best substitute where the expense can be justified. In No. 2. the end is accomplished much more economically by *housing* the rafters in the head of the kingpost at the angle in which the rafters meet, by which the fibres of the rafters butt against each other, bringing the compression nearer to that which takes place in a post according as the rafters are less inclined to each other, and the beam is then literally suspended from the vertical planes of the rafters at their junction.

2034. When a roof (*fig. 685.*) is trussed by two upright suspending posts, which become necessary in increased spans, such posts, AB, CD, are called *queen-posts*, and the piece between them, BD, is called a *collar*, which acts as a *straining piece* to prevent the heads of the queen-posts moving out of their places towards each other. It will on mere inspection be seen that this roof has three points of support, B, E, and D; for by means of the struts AE, EC, a new suspending point is gained from E for sustaining the tie beam between the points A and C. It is also to be observed that the collar or straining piece BD performs in this assemblage an office exactly the reverse of that which it does in *fig. 681.*

2035. The *Mansard* roof, so called from its inventor's name, and with us called a *Curb roof*, frequently used for the purpose of keeping down the height of a building, and at the same time of obtaining sleeping or other rooms in it, is shown in *fig. 686.* It may be considered as primarily consisting of four pieces of timber connected by hinges at the points ABCDE. If these, as shown by the dotted lines, be inverted, they will arrange themselves by their gravity in such a manner that when returned to their first position they remain in a state of equilibrium, which, however, in practice, is but a tottering one, and requires additional expedients to prevent the whole assemblage thrusting out the walls; and, moreover, to prevent the upper rafters from acting by their thrust to displace the lower ones. To obtain these ends the first object is to introduce the tie AE (*fig. 687.*); and, secondly, the tie BD. It is to be understood that means are to be used, when needed from their length, to prevent these beams from bending, similar to those already directed in the cases of simple trusses. We have thus far endeavoured to explain in the simplest way the conduct to be pursued for obtaining stability in the construction of a roof; but

Fig. 683.

Fig. 684.

Fig. 685.

Fig. 686.

before we proceed to the scantlings of the timbers to be employed, the reader must be informed that the trusses to roofing, with whose nature he has now become acquainted, are placed only at certain intervals (which should not exceed 10 feet) apart, and are thus made to bear the *common rafters* and the weight of the covering, as well as to perform the office of suspending the tie beam by which the walls are kept together. Hence the rafters by the means of a *purline* A (fig. 688.), which lies horizontally throughout the roof's length on the principal rafters, they are made to bear all the superincumbent load. The purlines are in various ways made fast to the principal rafters, and upon it the common rafters are usually notched down. Their bearings are thus lessened, and less scantlings suffice for them.

They are received at their feet on a piece of timber (B in the figure), which runs longitudinally along the sides of the building. This piece of timber is called a *pole plate*, from being the uppermost plate in a building; at their summits they abut against a *ridge piece* D. When a roof slopes each way, the space enclosed between the intersection of the slopes is called a *hip* (fig. 689.); and the longest rafters in it, which are those at the angles, are called *hip rafters*, and the shorter ones are named *jack rafters*, as A, A, A, &c.

2036. We have, at the beginning of this section (2007.), observed, that the use made of bolts must be always in a direction as nearly as possible counter to the strain which the pieces exert; the method, therefore, of introducing them will, on due consideration, be sufficiently obvious.

Before proceeding to lay before the reader some few examples of roofs suitable to different spans, as well as of some of magnitude which have been executed, it may be as well to complete this portion of our labour, by giving some information on the scantlings of timber for roofing, in which a medium, founded on our own practice, is introduced between ignorant overloading, and fanciful theory.

2037. For roofs whose spans are between 20 and 30 feet, no more than a truss with a king-post and struts will be necessary, in which case the scantlings hereunder given will be sufficient.

For a span of 20 feet, the tie beam to be 9 in. by 4 in.; the king-post, 4 in. by 4 in.; principal rafter, 4 in. by 4 in.; struts, 4 in. by 3 in.

For a span of 25 feet, the tie beam to be 10 in. by 5 in.; the king-posts, 5 in. by 5 in.; principal rafter, 5 in. by 4 in.; struts, 5 in. by 3 in.

For a span of 30 feet, the tie beam to be 11 in. by 6 in.; the king-post, 6 in. by 6 in.; principal rafter, 6 in. by 4 in.; struts, 6 in. by 3 in.

2038. For roofs whose spans are between 30 and 45 feet, a truss with two queen-posts and struts will be required, and a straining piece between the queen-posts. Thus —

For a span of 35 feet, the tie beams to be 11 in. by 4 in.; queen-posts 4 in. by 4 in.; principals, 5 in. by 4 in.; straining piece, 7 in. by 4 in.; struts, 4 in. by 2 in.

For a span of 40 feet, the tie beams to be 12 in. by 5 in.; queen-posts, 5 in. by 5 in.; principals, 5 in. by 5 in.; straining piece, 7 in. by 5 in.; struts, 5 in. by 2½ in.

For a span of 45 feet, the tie beams to be 13 in. by 6 in.; queen-posts, 6 in. by 6 in.; principals, 6 in. by 5 in.; straining piece, 7 in. by 6 in.; struts, 5 in. by 3 in.

2039. For roofs whose spans are between 45 and 60 feet, two queen-posts are required, and a straining piece between them; struts from the larger to the smaller queen-posts, and struts again from the latter.

Fig. 687.

so framed in a truss are called principal rafters; and

Fig. 688.

Fig. 689.

For a span of 50 feet, tie beams, 13 in. by 8 in. ; queen-posts, 8 in. by 8 in. ; small queens, 8 in. by 4 in. ; principals, 8 in. by 6 in. ; straining piece, 9 in. by 6 in. ; struts, 5 in. by 3 in.

For a span of 55 feet, tie beams, 14 in. by 9 in. ; queen-posts, 9 in. by 8 in. ; small queens, 9 in. by 4 in. ; principals, 8 in. by 7 in. ; straining-piece, 10 in. by 6 in. ; struts,  $5\frac{1}{2}$  in. by 3 in.

For a span of 60 feet, tie beams, 15 in. by 10 in. ; queen-posts, 10 in. by 8 in. ; small queens, 10 in. by 4 in. ; principals, 8 in. by 8 in. ; straining piece, 11 in. by 6 in. ; struts, 6 in. by 3 in.

2040. The scantlings of purlines are regulated principally by their bearing ; and though we have subjoined scantlings for bearings of 12 feet, such should be avoided by not allowing the distances between the trusses to exceed 10 feet. Thus —

For a bearing of 6 feet, the scantling of the purline should be 6 by 4.

8 feet,	—	7 by 5.
---------	---	---------

10 feet,	—	8 by 6.
----------	---	---------

12 feet,	—	9 by 7.
----------	---	---------

For common rafters the scantlings are as follow ; 12 feet should be the maximum of the bearing.

For a bearing of 8 feet the scantling of the rafter should be 4 by  $2\frac{1}{2}$ .

10 feet,	—	5 by $2\frac{1}{2}$ .
----------	---	-----------------------

12 feet,	—	6 by $2\frac{1}{2}$ .
----------	---	-----------------------

2041. By a study of the roofs which follow as examples, the architect will be led to other expedients and modifications of the forms submitted to his notice, as circumstances may call forth his ingenuity and talents. We have, we trust, already said enough to lead him on. Where economy must be consulted, the roof shown in *fig. 690.* may be used ; it is only fit for a small building, and the span of such a one should not exceed 25 feet. The left end of the collar beam exhibits what is called the *carpenter's boast*, but it partakes somewhat of the rule joint, being worked out to a centre. But in roofs above 25 feet span it is not well to omit the king-post and tie beam, though, if particular strains are to be provided against, even in such small spans the struts should not be omitted, and the form shown in

Fig. 690.

Fig. 691.

Fig. 692.

*fig. 691.* should be adopted, which will answer for spans at least up to 35 feet. In this and other cases of larger span, it is often desirable that the common rafters should not stand above the principals, and then the purlines are framed by mortices and tenons into the principals, as shown at A (*fig. 692.*), wherein the line *bc* shows the underside of the common rafters notched on to the principals.

2042. From 35 to 45 feet, the tie beam should be suspended from at least three points, or it will be unnecessarily heavy ; and this suspension of the tie beam, so that it may be really a tie unsusceptible of alteration in form, is the true cause of this introduction of king and queen posts, as we have before explained to the reader. Indeed, as a general rule, it is well that the distance between such points of support for a tie-beam should not exceed 13 to 15 feet, without expedients being used to prevent intermediate sagging. *Fig. 693.* is the form of a roof for a span of from 50 to 60 feet, in which is seen the connection of the roof with the walls.

Fig. 693.

2043. For spans above 60 feet we have not given scantlings of timber in the preceding tables ; but such do not greatly increase beyond 60 feet with practicable spans, and enough has been already said to make the reader acquainted with that part of the subject. *Fig. 694.* is an example of a roof calculated for a span of 70 to 80 feet, and in *fig. 695.* a passage or other conveniency may be practised between the queen-posts.

Fig. 694.

Fig. 695.

2044. In all the cases given, the roof is supposed to receive no support from any but the external walls, and the trusses to be not more than 10 feet apart.

2045. We shall now proceed to offer a few examples of roofs that have been executed, all of which have already appeared in works relating to the subject, as specimens of the most instructive and useful class for the student. The reader who desires to extend his inquiry into this branch of carpentry, and to become acquainted with a multitude of examples, is recommended to the celebrated work of Kraaft, *Recueil de Charpente*, and also to Rondelet's admirable treatise *L'Art de Batir*. The space to which we are limited prevents the insertion of many specimens which we would have gladly published here. The principles have, however, been so explained, that we trust the omission will not be felt. In respect of Gothic examples, a reference to the section of Westminster Hall (*fig. 196.*) will exhibit one of the modes adopted to span the large ancient halls of the country. In them the tie is rarely found connecting the feet of the principal rafters; for such an arrangement would have prevented the ornamental system which results from the substitution of a collar for a tie beam.

2046. *Fig. 696.* represents a section of the roof of St. Martin's-in-the-Fields, Westminster,

Fig. 696.

designed by Gibbs. The breadth of the building between the walls is 69 ft.; from centre to centre of columns the middle aisle is 39 ft. 11 in. The roof is well contrived and framed; but the timbers are stronger than they need have been. The scantlings of them are as follow:—A, principal rafter, 13 in. by 10 at bottom, and 11 in. by 10 at top; B, straining brace, 14 in. by 10 at bottom, and 11 in. by 10 at top; C, king-post, 9 in. by 9; D, strut, 7 in. by 7½; E, queen-post, 8 in. by 9½; F, strut, 7 in. by 7; G, tie beam, 14 in. by 9½; H, post over the column, 14 in. by 9½; I, brace, 7 in. by 7; K, brace, 7 in. by 7; L, post, 8 in. by 9; M, hammer beam, 14 in. by 9½; N, brace, 8 in. by 8; P, post in the wall; QQQ, purline rafters, 4 in. by 6.

2047. *Fig. 697.* is a section of the roof to the chapel of Greenwich Hospital, constructed

Fig. 697.

by Samuel Wyatt, about 1785. The span is 51 ft., and as a variety from the general forms of roofs, it is worth the student's attention. The scantlings of the timbers are subjoined; the distance between the trusses is about 7 feet, and the king-posts are of iron. All the joints are well secured with iron straps. AA, tie beam, whose whole length is 57 ft., 51 ft. clear between the walls, 14 in. by 12 in.; B, an iron king-post, 2 in. square; CC,

queen posts, 9 in. by 12; DDDD, struts, 9 in. by 7; E, straining beam, 10 in. by 7; F, straining piece, 6 in. by 7; GG, principal rafters, 10 in. by 7; hhhh, &c. purline rafters for boarding upon instead of rafters; H, a camber beam, supporting the platform.

2048. Fig. 698. exhibits the roof of the old Drury Lane Theatre, which was built in

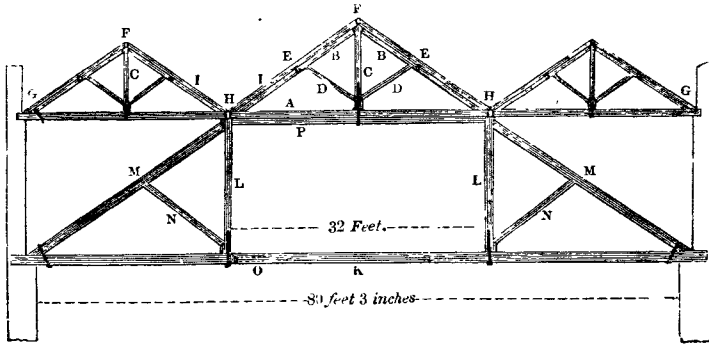

Fig. 698.

1793. It possesses great merit, from the simplicity of its composition and the accommodation afforded in the middle space for the carpenters and painters. By dividing the breadth of the building into three parts, the roof was kept low, and the scantlings much reduced in size. The span is 80 ft.  $3\frac{1}{2}$  in., the trusses were 15 ft. apart, and the whole length of the roof was 200 ft. It was destroyed by fire on the 24th of February, 1809. The scantlings of the timbers were as follow: — A, beams, 12 in. by 7; B, principal rafters, 7 in. thick; C, king-posts, 12 in. by 7; D, struts, 5 in. by 7; E, purlines, 9 in. by 5; F, ridge pieces,  $1\frac{1}{2}$  in. thick; G, pole plates, 5 in. by 5; H, gutter plates framed into beams, 12 in. by 6; I, common rafters, 5 in. and 4 in. by  $2\frac{1}{2}$ ; K, beams, 15 in. by 12; L, posts, 15 in. by 12; M, principal braces, 14 in. by 12 and 12; N, struts, 8 in. by 12; O, oak trusses to the middle bearing of beams,  $5\frac{1}{2}$  in. by  $4\frac{1}{2}$ ; P, straining beams, 12 in. by 12.

2049. The last example we shall present is of the method in which the external dome of St. Paul's is framed (fig. 699.). The internal dome Aa is of brickwork, two bricks thick, having, at every five feet, as it rises, a course consisting of bricks eighteen inches long, which serves to bind the whole thickness together. This dome was turned upon a centre, which rested upon the projection at its springing, without any support from below, and was afterwards left for the use of the painter. It was banded together with iron at the springing. Exterior to the brick dome (which has indeed, nothing immediately to do with the subject) is a cone of brickwork BBb, 1 foot 6 inches in thickness, plastered and painted, part whereof is seen from the pavement under the cupola through the opening a. On this cone BBb is supported the timber work which carries the external dome, whose hammer beams CC, DD, EE, FF are tied into the corbels G, H, I, K with iron cramps, which are well bedded into the corbels with lead, and bolted to the hammer beams. The stairs which lead to the Golden Gallery on the top of the dome are carried between the trusses of the roof. The dome is boarded from the base upwards, hence the ribs are fixed horizontally at near distances to each other. The scantling of the curve rib of the truss is 10 in. by  $11\frac{1}{2}$  at the bottom, and 6 in. by 6 at the top. The sides of the dome are segments of circles, whose centres are marked in the figure; and which, if continued, would meet at top, and form a pointed arch. Above the dome rises a lantern of Portland stone, about 21 feet in diameter, and 64 feet high, standing on the cone. The whole of this construction is manifest from the figure, which exhibits the inner and outer domes with the cone between them. The combination is altogether an admirable example of the mathematical skill and judgment of Sir C. Wren.

Fig. 699

2050. The largest roof that was, perhaps, ever executed, was over a riding-house at Moscow, built in 1790, by Paul I. Emperor of Russia, the representation whereof may be seen in Krafft, *Recueil de Charpente*. The span is 235 feet, and the slope with the horizon about 19 degrees. The external dimensions of the building were 1920 feet long by 310 feet wide. It was lighted by a lantern at top, and had an interior gallery round the building for spectators. The contrivance is exceedingly ingenious; but, from the great extent of the span, considerable settlement took place, and alterations, or rather strengthening ribs, became necessary.

2051. We shall close this part of the section with a diagram (fig. 700.) of the roof of

Fig. 700.

the basilica of S. Paolo fuori le mura, executed in the fifteenth century. The trusses are double, each consisting of two similar frames, nearly 15 inches apart, at intervals from each other of about 10 feet 6 inches. The principal rafters abut on a short-king post *k*. Between the trusses a piece of timber *S* is placed and sustained by a strong key of wood passing through it and the short king-posts. This piece sustains the beams by means of another strong key at *a*. The tie beams are in two lengths, and scarfed together, the scarf being held together by three iron straps. The scantlings of the timbers are as follow: beams *t*, 22½ in. full by nearly 15 in.; principal rafters *p*, 21½ in. by nearly 15 in.; auxiliary rafters *b*, full 13½ in. by full 13½ in.; straining beam *c*, near 15 in. by full 12½ in.; purlins *d*, 8½ in. square and 5 ft. 7 in. apart; common rafters, full 5½ in. by 4½ in., and 8½ in. apart. The roof, which is constructed of fir, is nearly 78 ft. 6 in. span, and is covered with the Roman tile, the exact dimensions and form whereof will be found, under the head TILE, in the Glossary appended to this work. The roof is ingeniously and well contrived, and, with a different covering, would suit other climates. It was consumed by fire in the month of July, 1823. (275)

Philibert Delorme, in his work entitled "*Nouvelles Inventions pour bien bâtir a petits Frais*," Paris, 1561, gives a mode of constructing domes without horizontal cross ties, when the springing of each rib is well secured at the foot. It is a very simple method, and of great use in domes, even of large diameter, the principle being that of making the several ribs in two or more thicknesses, which are cut to the curve in lengths not so great as to weaken the timber, and securing these well together by bolts or keys, and observing especially to break the joints of the several thicknesses. This method was adopted in the large Halle aux bleds at Paris, which was many years since destroyed by fire, and has been replaced by an iron-ribbed dome. The fig. 701. will explain the construction; and, if necessary, an iron hoop passed round at different heights will add much to the strength.

Fig. 701.

2052. The scantlings of the ribs, as given by Delorme, are as under:—

For domes of	24 feet diameter, the ribs to be	8 in. deep, and 1 in. thick.
	36 feet diameter, —	10 in. deep, and 1½ in. thick.
	60 feet diameter, —	13 in. deep, and 2 in. thick.
	90 feet diameter, —	13 in. deep, and 2½ in. thick.
	108 feet diameter, —	13 in. deep, and 3 in. thick.

The work of the author from which we have given this short and summary account deserves the study of every one that seeks to be an architect, though in these unfortunate days for the art the reward of study and reading is very doubtful; patronage being of much more importance to the professor than a profound knowledge of construction and design.

2053. The following instructions relative to the lines necessary to be found in the framing of roofs are from Francis Price's *British Carpenter*; and though published long since, now nearly 100 years, we have not found that any subsequent work on this particular point gives us more information than is to be there found. Let *abcd* (fig. 702.)

be a plan to be inclosed with a hipped roof, whose height or slope is Cb. Divide the plan lengthwise into two equal parts by the line *ef*, which produce indefinitely at both ends. Make *ag* equal *ea*, and *dk* equal to *df*, and through *k* and *g*, parallel to *ab* or *cd*, draw lines indefinitely *mo*, *lp*. With the distance *dc* or *Cc*, either of which is equal to the length of the common rafters, set off *qe*, as also from *h* to *p*, from *i* to *o*, and from *f* to *n*; from *k* to *m*, and from *g* to *l*. Make *ts* equal to *Cb*, and *ab* equal to *ta*, which

FIG. 702.

points join; then either *aC* or *as* represents the length of the hip rafter, and joining the several lines *aqb*, *bpoc*, *cnd*, and *dmla*, they will be the *skirts* of the roof.

2054. To find the back of the hip. Join *ge*, and from *r* as a centre describe an arc touching the hip *as*, and cutting *at* in *u*. Then join *gu* and *ue*, and *gue* is the back of the hip rafter required.

2055. Fig. 703. represents, in *abcd*, the plan of a building whose sides are bevel to each other. Having drawn the central line *ef* indefinitely, bisect the angle *ray* by the line *ae*, meeting *ef* in *e*. From *e* make *eg* equal to *re*, and *rg* perpendicular to *ea*; then, if *e* a be made equal to *eu*, *ra* or *aq*, it will be the length of the hip rafter from the angle *a*. Through *e* and *f*, perpendicular to the sides *db*, *ca*, draw the lines *np*, *mq* indefinitely; and from *a*, as a centre with the radius *aq*, describe an arc of a circle, cutting *mq* in *q*, and *er* (perpendicular to *ba*) produced in *l*. By the same kind of operation *oc* will be found, as also the other parts of the skirts of the roof. The lines *nt*, *tfr*, and *rp* are introduced merely to show the trouble that occurs when the beams are laid bevel. The angle of the back of the hip rafter, *rug*, is found as before, by means of *u* as a centre, and an arc of a circle touching *aq*. The backs of the other hips may be found in the same manner.

FIG. 703.

2056. Fig. 704., from Price's *Carpentry*, is the plan of a house with the method of placing the timbers for the roof with the upper part of the elevation above, which, after a perusal of the preceding pages, cannot fail of being understood. The plan F is to be prepared for a roof, either with hips and vallies, or with hips only. The open spaces at G and H are over the staircases: in case they cannot be lighted from the sides, they may be left to be finished at discretion. The chimney flues are shown at IKLMNO. Then, having laid down the places of the openings, place the timbers so as to lie on the piers, and as far as possible from the flues; and let them be so connected together as to embrace every part of the plan, and not liable to be separated by the weight and thrust of the roof. P is a trussed timber partition, to discharge the weight of the roof over a salon below.

2057. Q is the upper part of the front, and R a pediment, over the small break, whose height gives that of the blank pedestal or parapet S. Suppose T to represent one half of the roof coming to a point or ridge, so as to span the whole at once, "which," as Price truly observes, "was the good old way, as we are shown by Serlio, Palladio," &c., or suppose the roof to be as the other side U shows it, so as to have a flat or sky-light over the lobby F, its balustrade being W; or we may suppose X to represent the roof as spanning the whole at three times. If X be used, the valley and hip should be framed as at Y; if as T, the principal rafters must be framed as at Z, in order to bring part of the weight of the roof and covering on the partition walls. The remainder needs not further explanation.

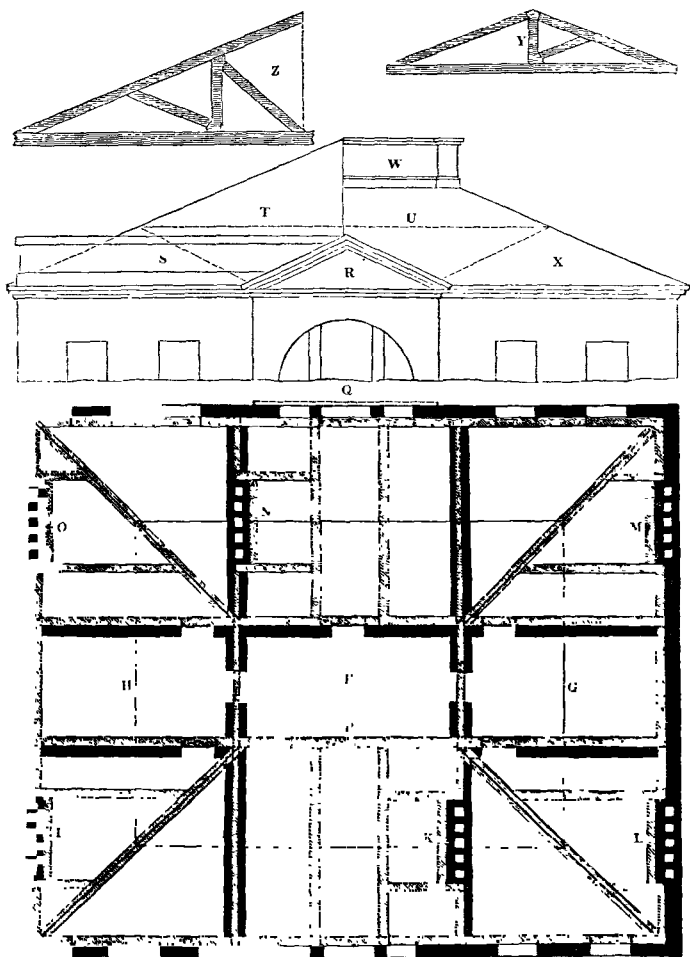

FIG. 704.

## RIBS FOR GROINS, ETC.

2058. We shall now proceed to the method of forming the ribs for groined arches, niches, &c. The method of finding the shape of these is the same, whether for sustaining plastering or supporting the boarding of centres for brick or stone work, except that, for plaster, the inner edge of the rib is cut to the form, and, in centering, the outer edge. Groins, as we have already seen, may be of equal or unequal height, and in either case the angle rib may be straight or curved; and these conditions produce the varieties we are about to consider.

2059. To describe the parts of a groin where the arches are circular and of unequal height, commonly called **WELSH GROINS**. We here suppose the groin to be right-angled. Let  $AB$  (fig. 705.) be the width of the greater arch. Draw  $BD$  at right angles to  $AB$ , and in the straight line  $BD$  make  $CD$  equal to the width of the lesser arch. Draw  $DF$  and  $CE$  perpendicular to  $BD$  and  $EF$  parallel to  $BD$ . On  $AB$  describe the semicircle  $BghiA$ , and on  $EF$  describe the semicircle  $EgroF$ . Produce  $AB$  to  $p$ , and  $FE$  to  $m$ , cutting  $Ap$  in  $y$ . Through the centre  $x$  of the semi-

Fig. 705.

circle *Eg* *r* *s* *F* draw *ts* perpendicular to *BD*, cutting the circumference of the semicircle in *s*. Draw *sp* parallel to *BD*. From the centre *y*, with the distance *yp*, describe the quadrant *pm*. Draw *mi* parallel to *AB*, cutting the semicircle described upon *AB* in the point *i*. In the arc *Bi* take any number of intermediate points *g*, *h*, and through the points *ghi* draw *it*, *hu*, *gv*, parallel to *BC*. Also through the points *ghi* draw *gh*, *hl*, *im* parallel to *AB*, cutting *FE* produced in *k* and *l*. From the centre *y* describe the arcs *ku*, *lo*, cutting *AB* produced in *mo*. Draw *nq*, *or*, parallel to *BD*, cutting the lesser semicircular arc in the points *q*, *r*. Through the points *q*, *r*, *s* draw *qv*, *ru*, *st* parallel to *AB*; then through the points *tuv* draw the curve *turc*, which will be the plan of the intersection of the two cylinders. The other end of the figure exhibits the construction of the framing of carpentry, and the method in which the ribs are disposed.

2060. To describe the sides of a groin when the arches are of equal height and designed to meet in the plane of the diagonals. Let *af* and *al* (*fig. 706*.) be the axes of the two vaults, meeting each other in *a*, perpendicular to *af*. Draw *AB* cutting *af* in *w*, and perpendicular to *al*, draw *BG* cutting *al* in *b*. Make *wA* and *wB* each equal to half the width of the greatest vault, and make *bB* and *bG* each equal to half the width of the lesser vault. Draw *AH* and *BE* parallel to *af*, and draw *BH* and *DF* parallel to *al*, forming the parallelogram *DEHF*. Draw the diagonals *HD*, *FE*. On the base *AB* describe the curve *BdefA*, according to the given height *wf* of the required form, which must serve to regulate the form of the other ribs. Through any points *cde* in the arc *BdefA* draw the straight lines *eq*, *dr*, *es* cutting the diagonal *HD* at *q*, *r*, *s*. Draw *qh*, *ri*, *sk* parallel to *al* cutting the chord *BG* at the points *x*, *y*, *z*, *b*. Make *xh*, *yi*, *zk*, *bl* each respectively equal to *tc*, *ud*, *ve*, *wf*, and through the points *Ghikl* to *B*, draw the curve *GhiklB*. Draw *qm*, *rn*, *so*, *ap* perpendicular to *HD*. Make *qm*, *rn*, *so*, *ap* respectively equal to *tc*, *ud*, *ve*, *wf*, and through the points *D*, *m*, *n*, *o*, *p*, *H* draw a curve, which will be the angle rib of the groin to stand over *HD*; and if the groined vault be right-angled, all the diagonals will be equal, and consequently all the diagonal ribs may be made by a single mould.

Fig. 706.

2061. The upper part of the above figure shows the method of placing the ribs in the construction of a groined ceiling for plaster. Every pair of opposite piers is spanned by a principal rib to fix the joists of the ceiling to.

2062. The preceding method is not always adopted, and another is sometimes employed in which the diagonal ribs are filled in with short ribs of the same curvature (see *fig. 707*.) as those of the arches over the piers.

Fig. 707.

2063. The manner of finding the section of an aperture of a given height cutting a given arch at right angles of a greater height than the aperture is represented in *fig. 708*.

2064. When the angle ribs for a square dome are to be found, the process is the same as for a groin formed by equal arches crossing each other at right angles, the joints for the laths being inserted as in *fig. 707*; but the general construction for the angle ribs of a polygonal dome of any number of sides is the same as to determine the angle rib for a cove, which will afterwards be given.

2065. When a circular-headed window is above the level of a plane gallery ceiling, in a church for example, the cylindrical form of the window is continued till it intersects the plane of the ceiling. To find the form of the *curb* or pieces of wood employed for completing the aris, let *dp* (*fig. 709*.) be the breadth of the window in the plane of the ceiling. Bisect *dp* in *h*, and draw *h4* perpendicular to *dp*. Make *h4* equal to the distance the curb extends from the wall. Produce *4h* to *B*. Make

Fig. 709.

$AB$  equal to the height of the window above the ceiling, and through the three points  $d, B, p$  describe the semicircle  $ABC$  for the head of the window. Divide  $AB$  into any number of equal parts, as 4 at the points  $k, l, v$ ; and  $h4$  into the same number of equal parts at the points 1, 2, 3. Through the points  $klv$  draw the lines  $et, fu, gw$  parallel to  $dp$ , and through the points 1, 2, 3 draw the lines  $mg, nr, os$ . Make  $1m, 2n, 3o$  respectively equal to  $ke, lf, vg$ ; as also  $1q, 2r, 3s$  equal to  $kt, lu, vw$ ; that is, equal to  $ke, lf, vg$ . Then through the points  $dmno4$ , and also through  $pqrst4$ , draw a curve which will form the curb required. In the section  $X$  of the figure,  $AC$  shows the ceiling line, whereof the length is equal to  $h4$ , and  $AB$  is the perpendicular height of the window; hence  $BC$  is the slope.

2066. The construction of a niche, which is a portion of a spherical surface, and stands on a plan formed by the segment of a circle, is simple enough; for the ribs of a niche are all of the same curvature as the plan, and fixed (*fig. 710.*) in planes passing through an axis corresponding to the centre of the sphere and perpendicular to the plane of the wall. If the plan of the niche be a semicircle (*fig. 711.*) the ribs may be disposed in vertical planes.

2067. In the construction of a niche where the ribs are disposed in planes perpendicular to the horizon or plan, and perpendicular to the face of the wall, if the niches be spherical all their ribs are sections of the sphere, and are portions of the circumferences of different circles. If we complete the whole circle of the plan (*fig. 712.*), and produce the plan of any rib to the opposite side of the circumference, we shall have the diameter of the circle for that rib, and consequently, the radius to describe it.

2068. *Of forming the boards to cover domes, groins, &c.* The principles of determining the development of the surface of any regular solid have already been given in considerable detail. In this place we have to apply them practically to carpentry. The boards may be applied either in the form of gores or in portions of conic surfaces; the latter is generally the more economical method.

2069. *To describe a gore that shall be the form of a board for a dome circular on the plan.* Draw the plan of the dome  $ABD$  (*fig. 713.*), and its diameter  $BD$  and  $Ae$  a radius perpendicular thereto. If the sections of the dome about to be described be semicircular, then the curve of the vertical section will coincide with that of the plan. Let us suppose the quadrant  $AB$  to be half of the vertical section, which may be conceived to be raised on the line  $Ae$  as its base, so as to be in a vertical plane, then the arc  $AB$  will come into the surface of the dome. Make  $Ai$  equal to half the width of a board and join  $ei$ . Divide the arc  $AB$  into any number of equal parts, and through the points of division draw the lines  $1i, 2j, 3k, 4l$ , cutting  $Ae$  in the points  $efgh$  and  $ei$  in the points  $ijkl$ . Produce the line  $eA$  to  $s$ , and apply the arcs  $A1, 12, 23, 34$  to  $Am, mo, oq$  in the straight line  $As$ . Through the points  $mnoq$  draw the straight lines  $tn, up, vr$ , and make  $mn, op, qr$ , as also  $mt, ou, qv$ , respectively equal to  $ei, fj, gk$ ; then through the points  $inpr$  to  $s$ , and also through the points  $xtuv$  to  $s$ , draw two curves from the points  $x$  and  $i$  so as to meet each other in  $s$ ; and the curves thus drawn will include one of the gores of the dome, which will be a mould for drawing the boards for covering the surface.

2070. In polygonal domes the curves of the gore will bound the ends of the boards; as, for example, in the hexagonal dome

Fig. 710.

Fig. 711.

Fig. 712.

Fig. 713.

Fig. 714.

(fig. 714.), the plan being ABCDEFGH. Let  $i$  be the centre of the circle in which the hexagon may be inscribed. Draw the half diagonal  $iA$ ,  $iB$ ,  $iC$  perpendicular to any side  $AB$  of the plan. Draw the straight line  $ih$ , cutting  $AB$  in  $h$ . Let  $hlmZ$  be the outline of one of the ribs of the dome, which is here supposed to be the quadrant of a circle. Divide the arc  $hZ$  into any number of equal parts from  $h$  at the points  $lmn$ , and through these points draw  $lx$ ,  $my$ ,  $nz$ , cutting  $Bi$  at the points  $xyz$ , and  $ih$  at the points 1, 2, 3. Extend from the arcs  $hl$ ,  $lm$ ,  $mn$ , on the line  $hn$ , from  $h$  to  $o$ , from  $c$  to  $p$ , from  $p$  to  $q$ , and through the points  $opq$  draw the straight lines  $ru$ ,  $sn$ ,  $tw$  perpendicular to  $hn$ . Make  $ou$ ,  $pv$ ,  $qw$ , as also  $or$ ,  $ps$ ,  $qt$ , respectively equal to  $1x$ ,  $2y$ ,  $3z$ ; then through the points  $Arst$  draw a curve, and through the points  $uvw$  draw another curve, meeting the former one in the point  $n$ . Thus will be formed the gore or covering of one side of the hexagonal dome.

2071. When the plan of the base is a rectangle, as fig. 715., draw the plan  $ABCD$  and the diagonals  $AC$  and  $BD$ , cutting each other in  $E$ . Through  $E$  draw  $EI$  perpendicular to  $AB$  cutting  $AB$  in  $F$ , and through  $E$  draw  $EJ$  perpendicular to  $BC$ , cutting  $BC$  in  $G$ . Let the height of the dome be equal to half its breadth, and the section over the straight line  $EF$  a quadrant of a circle; then from the centre  $E$  describe the arc  $FH$ , its base being  $EF$ , and with the straight line  $EG$  as half the major axis of an ellipsis, and  $EF$  the minor axis, describe the quadrant  $GF$  of an ellipsis. Produce  $EF$  to  $I$ , and  $EG$  to  $J$ . Divide the arc of a quadrant  $FH$  from  $F$  into any number of equal parts, and extend the parts on the line  $FI$  to  $klm$ , through which draw the lines  $kq$ ,  $lr$ ,  $ms$ , &c. perpendicular to  $FI$ . Through the points 1, 2, 3, &c. draw  $ut$ ,  $xu$ ,  $yr$ , &c., cutting  $AE$  at  $u$ ,  $x$ ,  $y$ , and  $FE$  at  $t$ ,  $u$ ,  $v$ . Make  $k'n$ ,  $l'o$ ,  $m'p$ , also  $kq$ ,  $lr$ ,  $ms$ , respectively equal to  $tw$ ,  $ux$ ,  $vy$ , and through the points  $n'o'p'$  draw a curve, also through the points  $qrs$  draw another curve meeting the former in  $I$ ; then these two curves with the line  $AB$  will form the gore or boundary of the building of two sides of the dome. Also in the elliptical arc  $GF$ , take any number of points 1, 2, 3, and draw the lines  $1u'$ ,  $2x'$ ,  $3y'$ , parallel to  $BC$ , cutting  $EC$  in the points  $w'x'y'$ , and  $GE$  in the points  $t'$ ,  $u'$ ,  $v'$ . Extend the arcs  $G1$ ,  $12$ ,  $23$  from  $Gk'$ ,  $k'l'$ ,  $l'm'$ , upon the straight line  $GJ$ , and through the points  $k'l'm'$  draw the lines  $n'q'$ ,  $o'r'$ ,  $p's'$ . Make  $k'n'$ ,  $l'o'$ ,  $m'p'$ , also  $k'q'$ ,  $l'r'$ ,  $m's'$  respectively equal to  $t'w'$ ,  $u'x'$ ,  $v'y'$ , and through the points  $Bn'o'p'$  draw the curve  $BJ$ , and through the points  $Cq'r's'$  draw the curve  $CJ$ ; then  $BJC$  will be the gore required, to which the boards for the other two sides of the dome must be formed.

2072. A general method of describing the board or half gore of any polygonal or circular dome is shown in fig. 716. Let  $DE$  be half either of the breadth of a board or of one of the sides of a polygon,  $EF$  the perpendicular drawn from the centre. Draw the straight line  $AB$  parallel to  $EF$ , and draw  $EA$  and  $FB$  perpendicular to  $EF$ ; then upon the base  $AB$  describe the rib  $AC$  of the vertical section of the dome. Divide the curve  $AC$  into the equidistant arcs  $A1$ ,  $12$ ,  $23$ , and through the points of division draw the lines  $1g$ ,  $2h$ ,  $3i$  perpendicular to  $AB$  cutting  $EF$  at  $ghi$  and  $DF$  at  $klm$ . Produce  $FE$  to  $V$  and extend the arcs  $A1$ ,  $12$ ,  $23$  upon the straight line  $EV$  from  $E$  successively to the points  $opq$ . Through the points  $opq$  draw the lines  $or$ ,  $ps$ ,  $qt$  parallel to  $ED$ . Make  $or$ ,  $ps$ ,  $qt$  respectively equal to  $gh$ ,  $hl$ ,  $im$ ; then through the points  $r's't$  draw a curve, and  $DEV$  will be the half arc or half mould of the boarding.

Fig. 715.

Fig. 716.

Fig. 717

2073. To cover a hemispherical dome by boards moulded to portions of conic surfaces. Draw a vertical section of the dome ABC (fig. 717.) and divide the circumference into equal arcs  $Cd$ ,  $de$ ,  $ef$ . Through the centre E draw EB perpendicular to AC. Draw the chords  $Cd$ ,  $de$ ,  $ef$ , and produce all these chords till they meet the line EB, which they will produce in a convenient space; but those chords that are next to the bottom AC will require a distance too remote from AC; and for the present confining our attention to those cords which, when produced, would meet the line EB at a convenient distance from AC, let  $ef$  meet the axis EB produced in  $g$ , and from the point  $g$  as a centre with the distances  $ge$  and  $gf$  describe the arcs  $eh$  and  $fi$ . Then  $efih$  is the form of the board, so that its breadth is everywhere comprehended between the two concentric circles  $eh$  and  $fi$ , and when the boards are bent their edges fall on horizontal planes.

2074. We will here shortly repeat a method which has previously been given of describing an arc of a circle independent of its centre, as connected with this part of the subject, and useful in cutting out the boards of a dome where the centre is inaccessible or too distant for convenience. Let AB (fig. 718.) be the cord of the arc and CD its height in the middle. In this case AB will be bisected at C by the perpendicular CD. Draw the half chord AD, and perpendicular thereto draw AE, and through the point D draw EF parallel to AB; also draw AG and BH perpendicular to the chord AB cutting EF in the points G and H. Divide AC and ED each into the same number of equal parts, and draw lines through the corresponding points of division; these lines will converge, and if produced with the lines EA and FB, would all meet in one point. Divide AG into the same number of equal parts as the lines AC, ED, and from the points of division draw lines to the point D to intersect the former. A curve drawn through the points of intersection will form the arc of a circle. The other part DB is found in the same manner; and this is a convenient method, because any portion of a circle may be described within the width of a board.

Fig. 718.

2075. To find the relation between the height and the chord of the arc. Let  $abc$ , &c. (fig. 719.) be the middle points of the boards in the arc, and from  $a$  draw a line parallel to the base to meet the opposite curve; also from these points draw lines to the opposite extremity of the base; then each parallel is the base, as  $fa$ , and the distances  $eg$  intersected between it, and the point where the oblique line from its extremity cuts the middle vertical is the height of the segment.

Fig. 719.

2076. It is, however, more convenient to describe the curvature of the board by a continued motion, which may be done as follows. Let AB (fig. 720.) be the chord of the arc. Bisect AB at C by the perpendicular CD, and make CD equal to the height of the segment. Draw DE parallel to AB, and make DE a little larger than AD; then form an instrument ADE with laths or slips of wood, and make it fast by a cross slip of wood GH. By moving the whole instrument, so that the two edges DA and DE may slide on two pins A and D, the angular point D of the instrument will describe the segment of a circle, and if the pin be taken out of A and put in the point B, the other portion DB of the segment ADB will be described in the same manner.

Fig. 720.

2077. The covering of an elliptical dome is formed by considering each part a portion of the surface of a cone. ABC (fig. 721.) is a vertical section through the greater axis of the base; the other vertical section through the axis at right angles being a semicircle; the joints of the boards therefore fall in the circumference of vertical circles.

Fig. 721.

Fig. 722.

2078. In the same manner the covering of an annular vault whose section is semicircular is found, being on the same principles as now shown for a horizontal dome, which will be evident from an inspection of fig. 722.

## BRACKETING.

2079. The pieces of wood which sustain the laths of cornices, coves, and the like, are called *brackets*, and they take in form the general outlines as nearly as possible of the forms to which they are to be finished.

2080. A cornice bracket of any form being given, to make another similar one, or one that shall have the same proportions in all its parts. Let *ABCDEF* (*fig. 723.*) be the given bracket. Draw lines from the angular points *CDE*, and let *Ab* be the projection of the required bracket. The lines *AC*, *AD*, *AE*, being drawn, draw *bc* parallel to the edge *BC*, cutting *AC* in *c*; draw *cd* parallel to *CD*, cutting *AD* in *d*. Draw *de* parallel to *DE*, cutting *AE* in *e*, and draw *ef* parallel to *EF*, cutting *AF* in *f*. Then *Abcdef* is the bracket required.

Fig. 723.

2081. To form an angle bracket to support the plastering of a moulded cornice. Let *fig. 724.* *X* be the plan of the bracket. Draw the straight line *AE* equal to the projection *ab* of the bracket on the plan *X*, and *Aa* perpendicular to *AE*, to which make it equal. Join *Ea*, and on *AE* describe the given form *AFGHKLE* of the bracket which stands perpendicular to the line of course of the wall and the ceiling. From the angular points *FGHIKL*, draw the lines *Fa*, *Gb*, *Ic*, *He*, *Kd*, *Ld*, cutting *AE* in the points *BCD*, and *aE* in the points *a, b, c, d*. Draw *af*, *bg*, *ci*, *dk*, perpendicular to *aE*. Make *af*, *bg*, *ch*, *ci*, *dk*, *dl*, each respectively equal to *AF*, *BG*, *CH*, *CI*, *DL*, *DK*. Join *fg*, *gh*, *hi*, *ik*, *kl*, *le*. Then *afghikle* is the angle bracket required.

Fig. 724.

2082. An angle bracket for a cove (*fig. 725.*) may be described in exactly the same manner.

Fig. 725.

2083. When cove brackets have different projections, the method of describing the angle one is shown in *fig. 726.* Let *AB*, *BC* be the wall lines. Draw any line *GD* perpendicular to *AB* and *HF* perpendicular to *BC*. Make *GD* equal to the projection of the bracket from the wall represented by the line *AB*, and make *HF* equal to the projection of the bracket from the wall represented by *BC*. Then, as one of the brackets must be given, we shall suppose the bracket *GAD* described upon *GD*. Draw *DE* parallel to *AB*, and *FE* parallel to *BC*, and join *BE*. In the curve *AD* take any number of points *Q, S*, and draw *QP*, *SR* cutting *GD* in *P, R* and *BE* in *p, r*. From the points *p, r* draw the lines *pq, rs* parallel to *BC*, cutting *HF* in the points *p, r*. Draw *pq, rs* perpendicular to *BE*. Make *pq, rs* also *pq, rs* respectively equal to *PQ, RS*, &c. *Ba* and *HC* equal to *GA*, then through the points *aq, s*, &c. draw a curve which forms the bracket for the angle. Also through the points *C, q, s* draw another curve, and this will form the cove bracket.

Fig. 726.

2084. The angle bracket of a cornice or cove may be formed by the method shown in *X* and *Y* (*fig. 727.*), whether the angle of the room or apartment be acute or obtuse, external or internal. Let *ABC* be the angle. Bisect it by the line *BE*. Draw *GF* perpendicular to *BC*, and make *GF* equal to the projection of the bracket, *GC* equal to its height, and *FC* the curve of the given bracket or rib. In the curve *FC*, take any number of points *PQ*, and parallel to *BC* draw the lines *Pr, Qs*, cutting *BE* in the points *r, s*, and *GF* in the points *R, S*. Draw *rp, sq* perpendicular to *BE*, and make the ordinates *rp, sq* respectively equal to *rp, sq*, and through all the points *pq*, draw a curve, which will be the bracket as required.

Fig. 727.

2085. When the angle is a right angle, it may be drawn as at *fig. 728.*, which is an ornamental bracket for the string of a stair, and traced in the same manner as that on a right-angled triangle.

2086. In coved ceilings, the coves meeting at an angle are of different breadths, and the plan of the angle is a curve to construct the brackets. Let  $ABC$  (*fig. 729.*) represent the angle formed by the walls of the room, and let  $Bdefg$  be the plan of the bracket in the angle of a curvilinear form. Draw  $HM$ , and thereon describe the bracket  $HOPQ$  intended for that side, and in the curve  $HOQ$  take any number of points  $NOP$ , and draw the lines  $NR$ ,  $OS$ ,  $PT$  perpendicular to  $AB$ , cutting it in the points  $R$ ,  $S$ ,  $T$ . Let  $MQ$  be the height of the bracket, and draw  $QA$  perpendicular to  $BA$ , and through the points  $NOPQ$  draw the straight lines  $Nd$ ,  $Oe$ ,  $Pf$ , cutting  $HM$  at  $IKLM$ . Draw  $hm$  perpendicular to  $BC$ . Make  $hr$ ,  $hs$ ,  $ht$ ,  $ha$  respectively equal to  $HR$ ,  $HS$ ,  $HT$ ,  $HA$ , and draw  $rn$ ,  $so$ ,  $tp$ ,  $aq$  perpendicular to  $BC$ ; also from the points  $defg$  draw the lines  $dn$ ,  $eo$ ,  $fp$ ,  $gq$ , and through the points  $hnopq$  draw a curve, which will form the other bracket required.

Fig. 728.

2087. Whether brackets occur in external or internal angles, the method of describing them is the same, and when the brackets from the two adjacent walls have the same projection, one of them must be given to find the angle bracket. When the brackets from these walls have unequal but given projections, then the form of one of the brackets must be given in form to find the angle bracket.

2088. To form a bracket for a moulded cornice. On the drawing of such cornice, draw straight lines, so as to leave sufficient thickness for the lath and plaster, which should in no case be less than three-fourths of an inch. Thus the general form of the bracketing will be obtained.

Fig. 729.

## DOMES.

2089. We have, in a foregone page, mentioned a method of constructing domes with ribs in thicknesses. We here present to the reader two designs for dome-framing, wherein there is a cavity of framed work between the inner and outer domes; with moderate spans, however, simple framing is all that is required. *Fig. 730.* A is a design for a domical roof. B exhibits the method of framing the curb for it to stand upon, the section of the curb being shown upon *fig. A*. The design here given is nearly the same as that used for the dome of the Pantheon in Oxford Street, which was destroyed by fire. C is another design for a domical roof, which is narrow at the bottom part of the framing, for the purpose of gaining room within the dome.

Fig. 730.

## PENDENTIVES.

2090. If a hemisphere, or other portion of a sphere, be intersected (*fig. 731.*) by

Fig. 731.

cylindrical or cylindroidal arches, vaults  $aa$  are formed, which are called *pendentives*. The termination of these at top will be a circle, whereon may be placed a dome, or an upright drum story, which, if necessary, may be terminated by a dome.

The reader will immediately perceive that many varieties may be formed. Our object here is merely to show how the carpenter is to proceed in making his *cradling*, as it is called, when pendentives are to be formed in wood.

2091. To cove the ceiling of a square room with conical pendentives. Let ABC (fig. 732.) be half the plan of the room, and DFE the half plan of the curb, at whose top the ribs are all fixed. The hyperbolic arches *agb*, *bhc* on each of the four sides are of equal height. The straight ribs *bf*, *ik*, *lm*, &c. are shown on the plan by FB, IK, LM, &c. The method of finding the hyperbolic curves *agb*, *bhc* will be explained in the following figure.

Fig. 732.

Fig. 733.

2092. To find the springing lines of the preceding pendentives, the section in one of the vertical diagonal planes being given. Bisect the diagonal LK (fig. 733.) at the point N by the perpendicular NW, which make equal to the height of the cone, and draw the sides LW and KW. Bisect the side MK of the square at a, and on N, with the radius Na, describe an arc *aA*, cutting the diagonal LK at A. Then take any points B, C, D, between A and K, and with the several radii NB, NC, ND, describe the arcs Bb, Cc, and Dd, cutting KM at the points *d*, *c*, and *b*. From the points A, B, C, and D, draw AE, BF, CG, and DH perpendicular to the diagonal KL, cutting the side WK of the section of the cone at E, F, G, H. At the points *abcd* erect perpendiculars *ae*, *bf*, *cg*, and *dh* to the side ML, making each equal to their corresponding distances AE, BF, CG, and DH, which will be one half of the curve for that side from which the other may be traced. The dark parts show the feet of the ribs.

2093. Fig. 734. shows the method of coving a square room with spherical pendentives, which a few words will sufficiently describe. CD, DE are two sides of the plan; AFB is half the plan of the curb. In the elevation above is shown the method of fixing the ribs (which, in projection, are portions of ellipses) on two sides of the plan. *ab* is the elevation of the curb AFB; *efd* and *dge* are ribs on each side of the plan supporting the vertical ribs that form the spherical surface, which vertical ribs support the curb *afb*. On *afb* may, if necessary, be placed a lantern or skylight; or, if light be not wanted, a flat ceiling or a dome may be placed. This pendentive is to be finished with plaster; hence the ribs must not be farther apart than about 12 inches.

2094. For finding (fig. 735.) the intersection of the ribs of a spandrel dome, whose section is the segment of a circle, and whose plan is a square ABCD. Let DEFB be the section on the plane of the diagonal. First plan one quarter of the ribs, as at UC, TN, SL, RI, and QG, this last being parallel to DC or AB, the sides of the square; on V, with the radii VG, VI, VL, VN, and VC, describe the arcs GPg, Ili, Lul, Nvn, &c. cut-

Fig. 734.

ting the base DB of the angular rib in  $g, i, l$ , and  $n$ . Draw  $gh, ik, lm$ , and  $no$ , each perpendicular to DB, cutting the diagonal rib at  $h, k, m$ , and  $o$ . Then making the distances GH, IK, LM, and NO equal to the corresponding distances  $gh, ik, lm$ , and  $no$ , through the points H, K, M, O draw a curve which will be the under edge of that for the bottom of the ribs QG, RI, SL, TN, and UC, shown complete on each side of the square plan. If each of the circular segments on each side of the square plan be turned up at right angles to the plan ABCD, the ribs will then stand in their true position.

## BRIDGES.

2095. We shall in this work confine ourselves to the simplest forms of timber bridges, which, as well as those of stone, will be found fully treated of in the *Encyclopædia of Engineering*, by Mr. Cresy, which forms one of the series. They mostly depend on the principle of the truss, where the span is large; and this combination of timbers we have already explained, as in stone bridges the principle of construction of the arch is the chief matter for consideration, and to that a large portion of this work has been devoted; so that, on the part of the architect, we do not resign his pretension to employment in such works, for which, indeed, as respects design, his general education fits him better than that of the engineer.

2096. The bridge over the Brenta, near Bassano, by Palladio, is an example of a wooden bridge (*fig. 736.*), which is not only elegant as a composition, but one which is economical,

Fig. 735.

Fig. 736.

and might be employed with advantage where it is desirable that the piers should occupy a small space, and the river is not subject to great floods. The same great architect, in his celebrated *Treatise on Architecture*, has given several designs for timber bridges, the principles of whose construction have only been carried out further in many modern instances. He was the earliest to adopt a species of construction by which numerous piers were rendered unnecessary, and thus to avoid the consequences of the shock of heavy bodies against the piers in the time of floods. Of this sort was the bridge he threw over the rapid torrent of the Cismone (*fig. 737.*) whose span was 108 feet.

2097. Palladio has given a design for a timber bridge (*fig. 738.*) which is remarkable as having been the earliest that has come to our knowledge, wherein the arrangement is in what may be called framed voussoirs, like the arch stones of a bridge, a principle in later days carried out to a great extent, and with success, in iron as well as timber bridges.

Fig. 737.

Fig. 738.

2098. We shall conclude our section on practical carpentry with a method of constructing timber bridges proposed by Price in his *Treatise on Carpentry*, and one not dissimilar in principle to the method of Philibert de Lorme, before mentioned. The bridge (*fig. 739.*) is supposed to consist of two principal ribs *ik*. The width of the place is spanned at once by an arch rising one sixth part of its extent. Its curve is divided into five parts, "which," says Price, "I purpose to be of good seasoned English oak plank, of 3 inches thick and 12 broad. Their joint or meeting tends to the centre of the arch. Within this rib is another, cut out of plank as before, of 3 inches thick and 9 broad, in such sort as to break the joints of the other. In each of these ribs are made four mortices, of 4 inches broad and 3 high, and in the middle of the said 9-inch plank. These

Fig. 739.

mortices are best set out with a templet, on which the said mortices have been truly divided and adjusted. Lastly, put each principal rib up in its place, driving loose keys into some of the mortices to hold the said two thicknesses together; while other help is ready to drive in the joists, which should have a shoulder inward, and a mortice in them outward; through which keys being drove keep the whole together. On these joists lay your planks, gravel, &c.; so is your bridge compleat, and suitable to a river, &c. of 36 feet wide."

2099. "In case the river, &c. be 40 or 50 feet wide, the stuff should be larger and more particularly framed, as is shown in part of the plan enlarged, as I. These planks ought to be 4 inches thick and 16 wide; and the inner ones, that break the joints, 4 inches thick and 12 broad; in each of these are six mortices, four of which are 4 inches wide and 2 high; through these are drove keys which keep the ribs the better together; the other two mortices are 6 inches wide and 4 high; into these are framed the joists of 6 inches by 12; the tenons of these joists are morticed to receive the posts, which serve as keys, as shown in the section K, and the small keys as in L; all which inspection will explain. That of M is a method whereby to make a good butment in case the ground be not solid, and is by driving two piles perpendicularly and two sloping, the heads of both being cut off so as to be embraced by the sill or resting plate, which will appear by the pricked lines drawn from the plan I and the letters of reference." Price concludes: "All that I conceive necessary to be said further is, that the whole being performed without iron, it is therefore capable of being painted on every part, by which means the timber may be preserved; for though in some respects iron is indispensably necessary, yet, if in such cases where things are or may be often moved, the iron will rust and scale, so as that the parts will become loose in process of time, which, as I said before, if made of sound timber, will always keep tight and firm together. It may not be amiss to observe, that whereas some may imagine this arch of timber is liable to give way, when a weight comes on any particular part, and rise where there is no weight, such objectors may be satisfied that no part can yield or give way till the said six keys are broke short off at once, which no weight can possibly do."

## SECT. V.

## JOINERY.

2100. Joinery is that part of the science of architecture which consists in framing or joining together wood for the external and internal finishings of houses, such as the linings of walls and rough timbers, the putting together of doors, windows, stairs, and the like.

It requires, therefore, more accurate and nicer workmanship than carpentry, being of a decorative nature and near the eye. Hence the surfaces must be smooth and nicely wrought, and the joints must be made with great precision. The smoothing of the wood is called *planing*, and the wood used is called *stuff*, which consists of rectangular prisms roughly brought into shape by the saw, such prisms being called battens, boards, and planks, according to their breadth and thickness.

2101. We shall give but a succinct account of the joiner's tools; an acquaintance with their forms and uses being sooner learnt by mere inspection over a joiner's bench than by the most elaborate description.

#### TOOLS.

2102. The first is the *bench*, whose medium height is about 2 feet 8 inches, its length about 10 or 12 feet, and its width about 2 feet 6 inches. One side is provided with a vertical board, called the *side board*, pierced with holes ranged at different heights in diagonal directions, which admit of pins for holding up the object to be planed, which is supported at the other end of it by a *screw* and *screw check*, together called the *bench screw*, acting like a *vice*. The *planes* used by the joiner are the *jack plane*, which is used for taking off the roughest and most prominent parts of the stuff, and reducing it nearly to its intended form. Its *stock*, that is, the wooden part, is about 17 inches long, 3 inches high, and  $3\frac{1}{2}$  inches broad. The *trying plane*, whose use is nearly the same as that last described, but used after it, the operation being performed with it by taking the shaving the whole length of the stuff, which is called *trying up*, whereas with the jack plane the workman stops at every arm's length. The *long plane*, which is used when a piece of stuff is to be tried up very straight. It is longer and broader than the trying plane, its length being 26 inches, its breadth  $3\frac{3}{4}$  inches, and depth  $3\frac{1}{2}$  inches. The *jointer*, which is still longer, being 2 feet 6 inches long, and is principally used for obtaining very straight edges, an operation commonly called *shooting*. With this the shaving is taken the whole length in finishing the joint or edge. The *smoothing plane*, which, as its name imports, is the last employed for giving the utmost degree of smoothness to the surface of the wood, and is chiefly used for cleaning off finished work. It is only  $7\frac{1}{2}$  inches long, 3 inches broad, and  $2\frac{3}{4}$  inches in depth. The foregoing are technically called *bench planes*.

2103. The *compass plane* which in size and shape is similar to the smoothing plane, except that its under surface or *sole* is convex, its use being to form a concave cylindrical surface. Compass planes are therefore of various sizes as occasion may require. The *forkstaff plane* resembles the smoothing plane in size and shape, except that the sole is part of a concave cylindric surface, whose axis is parallel to the length of the plane. The form is obviously connected with its application, and, like the last named, it is of course of various sizes. The *straight block* is employed for shooting short joints and mitres, instead of the jointer, which would be unwieldy: its length is 12 inches, its breadth  $3\frac{1}{2}$  inches, and depth  $2\frac{3}{4}$  inches.

2104. There is a species of planes called *rebate planes*, the first whereof is simply called the *rebate plane*, being, as its name imports, chiefly used for making rebates, which are receding planes formed for the reception of some other board or body, so that its edge may coincide with that side of the rebate next to the edge of the rebated piece. The length of the rebate plane is about  $9\frac{1}{2}$  inches, its depth about  $3\frac{1}{2}$  inches, and its thickness varies according to the width of the rebate to be made, say from  $1\frac{1}{2}$  to  $\frac{1}{2}$  inch. Rebate planes vary from bench planes in having no *tote* or handle rising out of the stock, and from their having no orifice for the discharge of the shavings, which are discharged on one side or other according to the use of the plane. Of the sinking rebating planes there are two sorts, the *moving fillister* and the *sash fillister*, whereof, referring the reader to the tool itself, a sight of which he can have no difficulty in procuring, the first is for sinking the edge of the stuff next to the workman, and the other for sinking the opposite edge, whence it is manifest that these planes have their cutting edges on the under side. Without enumerating many other sorts which are in use, we shall mention merely the *plough*, a plane used for sinking a cavity in a surface not close to the edge of it, so as to leave an excavation or hollow, consisting of three straight surfaces forming two internal right angles with each other, and the two vertical sides two external right angles with the upper surface of the stuff. The channel thus cut is called a *groove*, and the operation is called *grooving* or *plowing*. This species will vary according to the width from the edge; but it is generally about  $7\frac{3}{4}$  inches long,  $3\frac{3}{4}$  inches deep.

2105. *Moulding planes* are for forming mouldings, which, of course, will vary according to the designs of the architect. They are generally about  $9\frac{3}{4}$  inches long, and  $3\frac{3}{4}$  inches deep. When mouldings are very complex, they are generally wrought by hand; but when a plane is formed for them they are said to be *stuck*, and the operation is called *sticking*.

2106. The *bead plane* is used very frequently in joinery, its use being for sticking mouldings whose section is semicircular; when the bead is stuck on the edge of a piece of stuff to form a semi-cylindric surface to the whole thickness, the edge is said to be

beaded or rounded. When a bead is stuck so that it does not on the section merely fall in with its square returns, but leaves a space , thus, between the junctions at the sides, it is said to be *quirked*. The beads or planes vary from very small sizes up to the  $\frac{3}{4}$  inch and  $\frac{7}{8}$  bead. They may however be larger, and are sometimes stuck double and triple. The *snipebill plane* is one for forming the *quirk*, whereof we have spoken; but we do not think a detailed description of it necessary, more than we do of those which are made for striking *hollows* and *rounds*.

2107. The *stock and bit* is the next tool to be mentioned. Its use is for boring wood, and the iron, which varies as the size of the bore required, is made in a curve on its edge of contrary flexure so as to discharge the wood taken out. It fits into what is called the *stock*, which has a double curved arm working on spindles, the end opposite to the bit being pressed by the body, whose weight against the whole instrument is the power whereby the operation is performed. The bit is also called a *pin*, or *gouge bit*. It is an important tool, and much used.

2108. *Countersinks* are bits for widening the upper part of a hole in wood or iron for the head of a screw or pin, and are formed with a conical head. *Rimers* are bits for widening holes, and are of pyramidal form whose vertical angle is about  $3\frac{1}{2}$  degrees. The hole is first pierced by means of a drill or punch, and the rimer then cuts or scrapes off the interior surface of the hole, as it sinks downwards, by pressing on the head of the stock. According to the metal on which they are to be used they are differently formed.

2109. The *taper shell bit* is conical both within and without. Its horizontal section is a crescent, the cutting edge being the meeting of the interior and exterior conic surfaces. Its use is for widening holes in wood. Besides the above bits, there are some which are provided with a screw-driver for sinking small screws into wood with more rapidity than the unassisted hand will accomplish.

2110. The *bradawl*, the smallest boring tool, is so well known, that it would be waste of space to do more than mention it, the commonest of instruments in the science of construction.

2111. The variety of *chisels* is great. They are well known to be edge tools for cutting wood by pressure on it, or by percussion with a mallet on its handle. The *firmer chisel* is a tool used by the carpenter as well as the joiner for cutting away superfluous wood by thin chips. Those are best which are made of cast steel. If much superfluous wood is to be cut away, a strong chisel, with an iron back and steel face, is first used with the aid of the mallet, and then a slighter one with a very fine edge. The first is the *firmer* first mentioned, and the last is called a *paring chisel*, in the use whereof the force employed is from the shoulder or hand.

2112. The *mortice chisel*, whose use is for cutting out rectangular prismatic cavities in stuff is made of considerable strength. The cavity it so cuts out is called a *mortice*, and the piece which fits into it a *tenon*, whence the name of the tool. This chisel is one acted on only by the percussion of the mallet.

2113. The *gouge* is used for cutting concave forms in stuff. It is, in fact, a chisel whose iron is convex.

2114. The *drawing knife* is an oblique-ended chisel, or old knife, for drawing in the ends of tenons by making a deep incision with the sharp edge, guided by that of the tongue of a square, for which purpose a small part is cut out in the form of a triangular prism. The use of this excavation is to enter the saw and keep it close to the shoulder, and thus make the end of the rail quite smooth, for by this means the saw will not get out of its course.

2115. There are many species of the *saw*, which is a thin plate of steel, whose edge is indented with teeth for cutting by reciprocally changing the direction of its motion. The varieties are—the *ripping saw*, which is used for dividing or splitting wood in the direction of the fibres; its teeth are large, the measure being usually to the number of eight in 3 inches, such teeth standing perpendicularly to the line which ranges with the points: the length of the *plate* or *blade* of this saw is about 28 inches. The *half ripper* is used also for dividing wood in the direction of the fibres: the plate of this saw is as long as of that last described, but it has only three teeth in an inch. The *hand saw*, whose plate is 26 inches long, contains fifteen teeth in 4 inches; it is used for cross cutting, as in the direction of the fibres; for which purposes the teeth recline more than in the two former saws. The *panel saw* has about six teeth in an inch, the length of its plate being the same as the last; but in this and the hand saw thinner than in the ripping saw: it is used for cutting very thin wood, either with or across the fibres. The *tenon saw* is most used for cutting wood transverse to the fibres, as the shoulders of tenons. The plate of a tenon saw is from 14 to 19 inches long, having eight to ten teeth in an inch. This saw not being intended to cut through the whole breadth of the wood, and the plate being too thin to make a straight kerf, or to keep it from buckling, it has a thick piece of iron fixed on the edge opposite to the teeth, called the back. From the opening for the fingers through the

handle of this and the foregoing saws being enclosed all round, it is called a double handle. The *sash saw* is used for forming the tenons of sashes ; its plate is 11 inches in length, having about thirteen teeth to the inch. It is sometimes backed with iron, but more frequently with brass. The *dovetail saw* is used for cutting the dovetails of drawers and the like ; its plate is backed with brass, it contains fifteen teeth in about one inch, and is about 9 inches long. The handles of this and the last saw are only single. The *compass saw*, for cutting wood into curved surfaces, is narrow, thicker on the cutting edge as the teeth have no set, and is without a back ; the plate, near the handle, is about an inch broad, and about a quarter of an inch at the other extremity, having about five teeth to the inch ; the handle is single. The *keyhole*, or *turning saw*, in its plate resembles the compass saw, but the handle is long, and perforated from end to end for inserting the plate at any distance within the handle ; there is a *pad* in the lower part of the handle, through which is inserted a screw for fastening the plate therein. As its name implies, it is used for turning out quick curves, as keyholes, and is therefore frequently called a keyhole saw.

2116. The teeth of all saws, except turning and keyhole saws, are bent alternately on the contrary sides of the plate, so that all the teeth on the same side are alike bent throughout the length of the plate, for the purposes of clearing the sides of the cut made in the wood by it. The saw is a tool of great importance in every case where wood is to be divided, for by its means it can be divided into slips or scantlings with no more waste than a small slice of the wood, whose breadth is equal to the depth of the piece to be cut through, and the thickness of it equal to no more than the distance of the teeth between their extreme points on the alternate sides of the saw measured on a line perpendicular to them ; whereas, by any other means, such as the axe for instance, large pieces of timber could only be reduced in size by cutting away the superfluous stuff, which would be no less a waste of labour than of the material used ; and even then it would have to be reduced to a plane surface.

2117. Joiners use the *hatchet*, which is a small axe, for cutting away the superfluous wood from the edge of a piece of stuff when the part to be cut away is too small to be sawed.

2118. The *square* consists of two rectangular prismatic pieces of wood, or one of wood, and the other, which is the thinnest, of metal, fixed together, each at one of their extremities, so as to form a right angle both internally and externally ; the interior right angle is therefore called the inner square, and the exterior one the outer square. Squares are, for different applications, made of different dimensions. Some are employed in trying up wood, and some for setting out work ; the former is called a trying square, and the latter a setting out square. To prove a square it is only necessary to reverse the blade after having drawn a line on the surface to which it is applied : if the line of the blade on reversal do not coincide with that first drawn, the square is incorrect.

2119. The bevel consists, like the square, of a blade and handle ; but the tongue is moveable on a joint, so that it may be set to any angle. When it is required to try up many pieces of stuff to a particular angle, an immoveable bevel ought to be made for the purpose ; for unless very great care be taken in laying down the moveable bevel, it will be likely to shift.

2120. The *gauge* is an instrument used for drawing or marking a line on a piece of stuff to a width parallel to the edge. It consists generally of a square piece with a mortice in it, through which runs a sliding bar at right angles, called the stem, furnished with a sharp point or tooth at one extremity, projecting a little from the surface ; so that when the side of the gauge next to the end which has the point is applied upon the vertical surface of the wood, with the toothed side of the stem upon the horizontal surface, and pushed and drawn alternately by the workman from and towards him, the tooth makes an incision from the surface into the wood at a parallel distance from the upper edge of the vertical side on the right hand. This line marks precisely the intersection of the plane which divides the superfluous stuff from that which is to be used. When it is required to cut a mortice in a piece of wood, the gauge has two teeth in it, and is called a *mortice gauge*, one tooth being stationary at the end of the stem, and the other moveable in a mortice between the fixed tooth and the head ; so that the distances of the teeth from each other, and of each from the head, may be set at pleasure, as the thickness of the tenon may require.

2121. The *side hook* is a rectangular prismatic piece of wood, with a projecting knob at the ends of its opposite sides. The use of the side hook is to hold a board fast, its fibres being in the direction of the length of the bench, while the workman is cutting across the fibres with a saw or grooving plane, or in *traversing* the wood, which is planing it in a direction perpendicular to the fibres.

2122. The *mitre box* consists of three boards, two, called the sides, being fixed at right angles to a third, called the bottom. The bottom and top of the sides are all parallel ; the sides of equal height, and cut with a saw in two directions of straight surfaces at right angles to each other and to the bottom, forming an angle of 45 degrees with the sides. The mitre box is used for cutting a piece of tried up stuff to an angle of 45 degrees with two

of its surfaces; or at least to one of the arrisses, and perpendicular to the other two sides, or at least to one of them, obliquely to the fibres.

2123. The *straight edge* is a slip of wood made perfectly straight on the edge, in order to make other edges straight, or to plane the face of a board straight. It is made of different lengths, according to the required magnitude of the work. Its use is obvious, as its application will show whether there is a coincidence between the straight edge and the surface to which it is applied. When joiners wish to ascertain whether the whole surface of a piece of wood lies in the same plane, they use two slips, each straightened on one edge, with the opposite edge parallel, and both pieces of the same breadth between the parallel edges; whence each piece has two straight edges or two parallel planes. To find, therefore, whether a board is twisted, one of the slips is placed across one end and the other across the other end of the board, with one of the straight edges of each upon the surface. The joiner then looks in a longitudinal direction over the upper edges of the two slips, until his eye and the said two edges are in one plane; or otherwise the intersection of the plane passing through the eye and the upper edge of the nearest slip will intersect the upper edge of the farthest slip. If it happen as in the former case, the ends of the wood under the slips are in the same plane; but should it happen as in the latter, they are not. In the last case, the surface is said to *wind*; and when the surface is so reduced as for every two lines to be in one plane, it is said to be *out of winding*, which is the same as to say it is a perfect plane. From the use of these slips, they are denominated *winding sticks*.

2124. The *mitre square*, an instrument so called because it bisects the right angle or mitres the square, is an immoveable bevel, for the purpose of striking an angle of 45 degrees with one side or edge of a piece of stuff upon the adjoining side or edge of the said piece of stuff. It consists of a broad thin board, let or tongued into a piece on the edge called the fence or handle, which projects equally on each side of the blade, whereof one of the edges is made to contain an angle of 45 degrees with the nearest edge of the handle, or of that in which the blade is inserted. The inside of the handle is called the guide. The handle may be about an inch thick, 2 inches broad; the blade about  $\frac{3}{16}$  to  $\frac{1}{4}$  of an inch thick, and about 7 or 8 inches broad. As the different sorts of mouldings used in architecture will be hereafter properly defined and treated on, we shall not now stop to describe them otherwise than as immediately connected with the section under consideration. The wood used for joinery is of two sorts, white and yellow deal; the first for panelling, and the last for framing. Of late years, much American wood has been used in joinery, both for panels and frames. It works easily, is soft, free from knots, but more liable to warp than white deal.

2125. The *arris* of a piece of stuff is the edge formed by two planes.

#### MOULDINGS.

2126. When the edge of a piece of wood is reduced to a cylindrical form, it is said to be *rounded*, which is the simplest kind of moulded work. (Fig. 740.) When a portion of the arris is made semicylindrical, so that the surface of the cylindrical part is flush both with the face and edge of the wood, with a groove or sinking made in the face only, the cylindrical part is called a *bead*, and the sinking a *quirk*; the whole combination (fig. 741.) being called a *quirked bead*.

2127. If a quirk is also formed on the other or returning face, so as to make the rounded part at the angle three fourths of a cylinder, the moulding (see fig. 742.) is called a *bead and double quirk*.

2128. If two semicylindrical mouldings both rise from a plane parallel to the face, and one comes close to the edge of the piece and the other has a quirk on the further side, and its surface flush with the face of the wood, as in fig. 743., the combination is called a *double bead* or *double bead and quirk*, wherein the bead next to the edge of the stuff is much smaller than the other.

2129. Mouldings are usually separated from one another, and often terminated by two narrow planes at right angles (fig. 744.) to each other: these are called *fillets*, and show two sides of a rectangular prism. The different pieces of the combination of mouldings are called *members*. A semicylindrical moulding, rising from a plane parallel to the face, and terminated on the edge by a fillet (fig. 745.), is called a *torus*. In the figure there are two hemicylindrical mouldings, whence that is called a *double torus*. The reader must observe that the distinction between torus mouldings and beads in joinery is, that the outer edge of the former always terminates with a fillet, whether the torus be single or double;

whereas a bead never has a fillet on the outer edge. A repetition of equal semicylindrical mouldings, springing from a plane or cylindrical surface, is called *reeds*. In joinery, the , *cima recta*, and , *cima reversa*, are called respectively the *ogee* and *ogee reverse*. The *ovolo* , so named from its egg-like form, and the *quarter round*, the fourth part of a cylindrical surface, are the remaining of the principal mouldings used in joinery. When the margin of any framing terminates on the edges next to the panel, with one or more mouldings, which both advance before and retire from the face of the framing to the panelling, the mouldings thus introduced are called *belection mouldings*.

## DOORS.

2130. We shall now more particularly address ourselves to the subject of doors and their mouldings. The most inferior sort of door used in building is the *common ledged door*, in which five or six or seven vertical boards are held together by usually three horizontal pieces called ledges, to which the vertical ones are nailed. Sometimes there is an outer framing, consisting of the top rail and the two outside styles, but still having ledges as before; these are called *framed and ledged doors*. A door, properly made, is formed by those framing and fitting pieces of stuff together of the same thickness; those which are horizontal (fig. 746.) AAAA being called *rails*, and those which are vertical BBBB being called *styles*. These form a skeleton into which *panels*, usually of a less thickness, are fitted. And this, indeed, is the general practice in all systems of framed joinery. In doors, the upper rails are called *top rails*; the next in descending, *frize rails*; the next, which are usually wider than the two first, are called the *lock or middle rails*; and the lowest, from their situation, are called *bottom rails*. The styles on the flanks are called *outside styles*, and those in the middle are called *middle styles*. The panels are also named from their situations on the door; thus CC, being the uppermost, are called *frize panels*; the next DD are called *middle panels*, and EE *bottom panels*. The rails and styles are wedged together, being previously morticed and tenoned into each other. The student should, however, to obtain a clear comprehension of the method adopted, see a door put together at the bench. The varieties and forms of doors are dependent upon the will of the architect, from whom the design of the whole emanates; it will be, therefore, here sufficient to mention the three sorts, viz. the *common door*, just described; the *jib door*, which is made with the same finishings and appearance as the room in which it is placed, so as not to have the appearance of a door; and, lastly, *folding doors*, which open from the centre of the doorway, and are used for making a wider communication between two apartments than a common door will permit, or, in other words, to lay two rooms into one.

FIG. 746.

2131. Though the panelling of framed work is generally sunk within the face of the framing, it is for outside work sometimes made flush. In the best flush work, the edge of the framing, and the work is called *bead and flut*. The bead is run on to the two sides of the panel in the direction of the grain of the wood. The flut is run on to the top and bottom of the panel in the direction of the grain of the wood. The figures by which the one of the styles, wherein only a small part of the panel is vertical sections, through the top rail and part of the panel below it.

2133. Fig. 747. represents the commonest door. It is without mouldings, and the panel is a straight surface on both sides. It is technically described, first mentioning the number

FIG. 747.

FIG. 748.

FIG. 749.

FIG. 750.

FIG. 751.

of panels intended in it, as a *door square and flat panel on both sides*. We shall not, in the following, repeat the observation as to the number of panels, that being always supposed as mentioned.

2134. Fig. 748. represents the rail and panel of a door, with a quirked ovolo and a

fillet on one side, but having no mouldings on the other. The panel flat on both sides, it is described as *door with quirked ovolo, fillet and flat with square back*.

2135. *Fig. 749.* only differs from the last in having a bead instead of a fillet, and is described as *quirked ovolo, bead and flat panel with square back*.

2136. *Fig. 750.*, with an additional fillet on the framing, is described as *quirked ovolo, bead fillet and flat panel with square back*. The back, in the foregoing and following cases, is described as square, because of its having no mouldings on the framing, and of the panel being a straight surface on one side of the door.

2137. In *fig. 751.* the framing is formed with a quirked ogee, and a quirked bead on one side and square on the other, the surface of the panel being straight on both sides, and the door is described as *quirked ogee, quirked bead and flat panel with square back*.

2138. *Fig. 752.* only differs from the last in the bead being raised above the lower part of the ogee and a fillet. It is described as *quirked ogee, cocked bead and flat panel with square back*.

2139. *Fig. 753.* is described as a door with *cove, cocked bead, flat panel and square back*.

Fig. 752.

Fig. 753.

Fig. 754.

Fig. 755.

2140. *Fig. 754.* is a combination, by which much strength is imparted to the door, and it is therefore much used for external doors. It is, however, often in the interior of houses, and is described, *quirked ovolo, bead fillet and raised panel on front and square back*. It is from the raising of the panel that the additional strength is acquired.

2141. *Fig. 755.* resembles the last in general appearance, the difference being in the ovolo on the raised panel. It is described, *quirked ovolo, bead and raised panel, with ovolo on the raised panel and square back*. When an external door has raised panels, they are always placed towards the exterior.

Fig. 756

Fig. 757.

Fig. 758.

Fig. 759.

2142. In *fig. 756.* there are more mouldings than in the last on the raised panel. It is described, *quirked ogee, raised panel with ovolo and fillet on the rising and astragal on the flat of panel in front and square back*.

2143. *Fig. 757.* is described, *quirked ovolo, bead fillet and flat panel on both sides*. This description of doors is used where a handsome appearance is to be equally preserved on both sides of the door, as between rooms, or between halls or principal passages and rooms.

2144. *Fig. 758.* is a combination used, as all bead butt and bead flush work is, where strength is required. The form here given is described, *bead and flush front and quirked ogee, raised panel with ovolo on the rising, grooved on flat panel on back*.

2145. The series of mouldings are, as we have before mentioned, called *bolection* mouldings (*fig. 759.*), and are laid in after the door is framed square and put together. They

project beyond the framing on each side. When bradded on through the sides of the quirks, the heads of the brads will be entirely concealed; but it is to be observed that, in driving the brads, they must not be directed towards the panels, but into the solid of the framing. The form of these bolection mouldings is of course varied according to the pleasure of the architect.

## SHUTTERS.

2146. *Shutters*, which are the doors of window openings, are framed upon the same principles as doors themselves; but their backs are very often flush. In the better sort of buildings they are folded into recesses called *boxings*, whereof we shall give a figure below as an example of the ordinary method; but as the extent and different forms of windows vary, the ingenuity of the architect will be often required to contrive his shutters within a very small space. Into minutiae we cannot enter in a work of this nature; however, in all their shapes, they are dependent on the leading principles given.

2147. *Fig. 760.* is a plan of the shutters, architrave, sash-frame, and part of the sash of common shutters. The cavity which forms the *boxing* into which the sashes fold is formed by the ground B (upon which the architrave A is nailed), the *back lining* F of the boxing, and the *inside lining* G of the sash frame, whereof H is the *inside bead*. L is the *outside lining* of the sash-frame, M the *back lining* of it, and K the *parting bead*, so called from parting the upper and lower sash. The vacant space between the pulley piece I and M, is a cavity which contains the weights for balancing the sashes, N shows the plan of the sash. The shutters, when stretched out in their different folds, are supposed to cover one half of the window, another series being supposed to be placed on the other side of it. The *front shutter* CCC is hung by hinges at *a* to the inside lining G of the sash-frame. The inner shutters DDD and EE are called the *back flaps*, the former whereof is hinged on to the front shutter at *b*, and the latter is hinged on to DDD at *c*. It will be immediately seen that these will thus altogether turn upon the hinges at *a*, and cover, in one straight line, from both sides, the whole of the light of the window; it being contrived that each boxing shall contain as many shutters as will cover one half, that is, from the centre of the hinge to the centre of the window. When the boxes are scanty, the hinge may be placed as shown in X attached to the figure.

2148. It would be impossible to place before the reader the infinite variety of examples required for the application of shutters to windows; in ordinary cases, the example we have given will sufficiently exhibit the method to be adopted. On occasions wherein it is not applicable, the architect must apply himself to the work *pro re nata*, in which, with very little attention, he will not find insurmountable difficulty.

Fig. 760.

## HINGING.

2149. A very essential consideration in the neatness and beauty of joiners' work, is the formation of the joints on which are placed the hinges of doors and shutters. They ought to be so continued as to preserve the uniformity of the door or shutter on both sides, and as much as possible to be close enough to exclude a rush of air between the edges of the bodies to be hinged together, which, in this cold climate, is essential. In these joints, both angles of one of the bodies is usually beaded, to conceal the open space, which would otherwise be seen; and for preserving the appearance of the work, the hinges are made of such a curvature towards the eye, as to seem, when painted, a part of the bead itself on that side where the knuckle is placed, so that when hung the whole may appear to be one bead.

2150. The section of a door style, and part of the *hanging style* at the joint, are represented in A and B (*fig. 761.*), wherein the centre of the bead on each side is in the line of the straight part of the joint from the opposite side. In this figure, C is the centre of the bead, AG part of the joint in a line with its edge. Joining AC, draw AB perpendicular thereto. The other part BH is perpendicular to EF, which

Fig. 761.

is the face of the door or hanging style. This is a joint suitable for many purposes, and may be made with common hinges. If crooked, it will assist in excluding the current of air, a point of no mean importance in this climate.

2151. In *fig. 762*. A and B exhibit a plane joint, beaded similarly on both sides. In this case, the plane of the joint is a tangent to the cylindrical surfaces of the two beads; and as the margin on each side is alike, no check to the rush of cold air is afforded. The hinge, moreover, is such that it cannot be made in the usual manner, but must be formed as at C.

Fig. 762.

Fig. 763.

Fig. 764.

2152. *Fig. 763*. A and B represent a hinging wherein the plane of the joint from one side is directed to the axis of the bead on the other. The principle in it is the same as that in *fig. 761.*, and it may therefore be hinged with common hinges, as shown in C, in which the two parts are conjoined. The methods shown in this and *fig. 761.* are useful in cases wherein a part of the margin is concealed on one side of the door.

2153. *Fig. 764*. A and B exhibit the beads of similar size on each side, and exactly opposite to each other, the joint being broken by indenting a part terminated by a plane directed to the axis of the two opposite beads. The hinges are required merely of the common form, the arrangement is strong, and the apartment rendered comfortable by their use. In C the parts are shown as hinged together.

2154. In *fig. 765*. the beads are on both sides, but not on the same piece, as in the last figure. The appearance is uniform, but the bead, which projects the whole of its thickness, is weakened. The junction is seen in the representation at C.

Fig. 765.

Fig. 766.

Fig. 767.

2155. *Fig. 766*. is a method that has been adopted for concealing the hinges of shutters. A is the inner bead of the sash-frame, B the inside lining, C the style of the shutter. For the form of the joint, let *af* be the face of the shutter, perpendicular to *ar* the face of the inside lining. Let the angle *f, a, r* be bisected by the straight line *aa*, and in the centre take *c*. Draw *dd* perpendicular to *aa*, cutting it in *c*, which is the centre of the hinge. From *c*, as a centre, describe the arc *am*, which must be hollowed out from the inside lining of the sash through the height of the shutter. In order to make room for the opening and shutting of the hinge, the internal right angle of the shutter must be cut out of its edge to the breadth of the hinges. The *toils* of the hinge are here for the purpose of strengthening them, represented of different lengths.

2156. In *fig. 767*. the hinges, which are for a door, are concealed, as the door allows it in the thickness of the wood, the ends of the hinges being of equal lengths.

2157. *Fig. 768*. shows the common method of hinging shutters, a mode wherein the whole thickness of the hinge is let into the thickness of the shutter, the inside lining being assumed as too thin to afford sufficient hold for the screws employed to fasten them.

Fig. 768.

Fig. 769.

2158. *Fig. 769*. exhibits the hanging of a door with the centres concealed. Let *ad* be the side of the jamb in contact with the edge of the door; bisect it in *b*, and draw *bc* perpendicular to *ad*, make *bc* equal to *ba* or *bd*, and join *ac* and *cd*; from *c*, as a centre, describe the arc *aed*, which will show the portion to be hollowed out of the jamb. The centres are fixed to the upper and under parts of the door, and the former is to be so constructed as to allow its being taken out of the socket to unhang the door when required.

2159. Shutters are usually hung in the way represented in *fig. 770.*, wherein the centre

of the knuckle of the hinge is exactly opposite to the perpendicular part of the rebate. The dotted lines exhibit the flap when folded back.

Fig. 770.

Fig. 771.

2160. When the axis of the knuckle cannot be disposed so as to fall opposite to the joint, the hinge is to be placed as shown in *fig. 771*. Thus, *ab* being the distance of the edge of the flap from that of the shutter, bisect it in *c*, which will be the point opposite whereto the centre of the hinge is to be placed. This arrangement is necessary, both when the shutters are not square at the ends, and when the boxing is restricted in space; the principle being to place the centre of the knuckle of the hinge at half the distance of the edge of the flap from the rebate on the edge of the shutter. In *fig. 772*, the two parts are shown hinged together.

Fig. 772.

2161. When a door has attached to it any projection, and, when open, it is requisite to bring it parallel to its place when shut, the knuckle of the hinge (*fig. 773*.) must project at least as far as the projection in question. An inspection of the diagram, wherein the dotted lines show the situation of the door when folded back, will sufficiently convey the mode of conducting this expedient.

Fig. 773.

2162. *Fig. 774*, is the representation of what is called a *rule joint*, which is used when the piece to be hung is not required to open to more than a right angle. In this case, the centre of the hinge is necessarily in the centre of the arc. In *fig. 775*, the expedient shows the method turned to a right angle.

Fig. 774.

Fig. 775.

2163. The various methods of hinging to suit every possible case would occupy a very large space, were we to enter into them; and even after exhausting all the cases that we may have imagined, others would arise to which no example given might be applicable; we therefore leave this portion of the subject of joinery, under an impression that the principles have been sufficiently developed to enable the student to pursue from them the application to any case that he may be called upon to put in practice.

#### SASH-FRAMES AND SASHES.

2164. In *fig. 760*, the connection between the shutters and sash-frame has been fully explained; we may now, therefore, proceed to the detail of a common sash-frame with its sashes, supposing them to be hung so as to be balanced by weights, suspended by sash-lines running over pulleys, capable of balancing those of the sashes themselves. On the case of *French sashes*, which open like doors, we do not think it necessary to dilate. They are, in fact, nothing more than glazed doors; and the principal object for attainment in their construction, is to prevent the rain from penetrating into the apartments they serve, as well where they meet in the middle as at their sills, which is a subject requiring much care and attention.

2165. In *fig. 776*, is shown the construction of a sash-frame, and the method of putting together the several parts, wherein *R* is the elevation of the frame, of which *ABCD* is the outer edge. The thinner lines at *EF*, *GH*, *FG*, are grooves whose distances from the edges of the sash-frame *LM* and *KI* are equal to the depth of the boxing, together with three-eighths of an inch more that is allowed for margin between the face of the shutter, when, in the boxing, and the edges *ML* and *KI* of the sash-frame next to the bead. *S* is a horizontal section of the sides, whereon is shown also the plan of the sill. *T* is a vertical section of the sill and top, in which is shown the elevation of the pulley style *m* and *n*, and the pulleys let into the pulley piece. *U* is the horizontal section of the sides, showing also a plan of the head of the sash-frame. *V* the elevation of the outer side of the sash-frame; the outside lining being removed for the purpose of showing the work within the sash-frame. In this *fig* is the *parting strip* fastened by a pin; *ed* one of the weights connected to the sash by means of a line going over the pulley *c*, the other end being fixed to the edge of the sash.

The weight *de* is made equal to one half the weight of the sash. *W* is the head of the sash-frame before put together, and *X* shows the edge of *W*. *Y* is the edge of the bottom, exhibiting the manner of putting the styles in it, and *Z* is the plan of *Y*. *Fig. 777.*, Nos. 1. and 2., are sections of the sills of sash-frames, with sections of the under rail of the sash, showing the best method of constructing them, in order to prevent rain from driving under the sash-rail. In each of these, *A* is the section of the bottom rail, *B* a section of the bead tongued into the sill, *C* a section of the sill. *Fig. 778.* exhibits sections of the meeting rails of the upper and lower sashes, with side elevations of the upright bars; *C* is the rebate for the glass, *D* a square, *E* and *F* an astragal and hollow moulding, *G* a fillet. The smaller letters mark the same parts of the under sash. *Fig. 779.* is the section of an upright bar with the plans of two horizontal bars, showing the *franking* or manner in which they are put together to keep the upright bars as strong as possible. The thickness of the tenon in

Fig. 776.

Fig. 777.

Fig. 778.

general is about one sixteenth of an inch to the edge of the hollow of the astragal, and close to the rebate on the other side. *hh* is a dowel to keep the horizontal bars still firmer together. In this diagram the letters refer to the same parts as in the preceding figure; and it is also to be observed, that no rebate is made for the glass on the inside meeting rail, a groove being made to answer that purpose. *Fig. 780.* exhibits four sections of sash bars. But their forms, as in the case of mouldings, generally depends on the taste of the architect.

#### GROUND.

2166. Grounds are pieces of wood framed together, and attached to walls, around windows, doors, or other openings in buildings, for the facility of fixing architraves or other mouldings upon them; in all these cases they ought to be fixed vertical on the face and edge, and the workman should take especial care to fix them firm and solid in every part; for, without accuracy and firmness, the inside work cannot be well finished to them, as it is to be recollected that in plastered rooms the plaster is worked to them.

Fig. 779.

Fig. 780.

2167. In fixing window grounds, the sash-frame must be first carefully placed so as to stand perfectly vertical; and then the face of the ground must stand quite parallel to the face of the sash-frame, and project about three quarters of an inch from the face of the naked brickwork, so as to leave a sufficient space for the thickness of the plaster. The edge of the ground should be in the same plane with the edge of the sash-frame, or, as the workmen term it, "out of winding." The edge of the architrave, when finished, in ordinary cases, will stand about three eighths of an inch within the inner edge of the sash-frame, so that a perpendicular line down to the middle of the grounds would stand exactly opposite to a perpendicular line down to the middle of the sash-frame.

#### FLOORS.

2168. In the laying of floors, the first care to be taken is that they be perfectly level, which, owing to the nature of the materials whereof they are constructed, is a difficult task. The chief sorts of floors may be divided into those which are *folded*, that is, when the boards are laid in divisions, whose side vertical joints are not continuous, but in bays of three, four, five, or more boards in a bay or fold; and those which are *straight joint*, in which the side joints of the boards are continuous throughout their direction.

As soon as the windows are fixed, the floors of a building may be laid. The boards are to be placed on their best face, and put to season till the sap is quite exhausted, when they may be planed smooth, and their edges shot and squared. The opposite edges are brought to a breadth by drawing a line on the face parallel to the other edge with a flooring guage, after which the common guage is used to bring them to a thickness, and they are rebated down on the back to the lines drawn by the guage.

2169. The next operation is, to try the joints, which, if not level, must be brought so, either by *furring up* if they be hollow, or by *adzing down* if they are convex, the former being more generally the case.

2170. The boards used for flooring are battens, or deals of greater breadth, whose qualities are of three sorts. The best is that free from knots, shakes, sapwood, or cross-grained stuff, selected so as to match well with one another. The second best is free of shakes and sapwood, and in it only small sound knots are permitted. The third, or most common sort, are such as are left after taking away the best and second best.

2171. The joints of flooring-boards are either quite square, ploughed and tongued, rebated, or doweled; and in fixing them they are nailed on one or both edges, when the joints are plain and square without dowels. When they are doweled, they may be nailed on one or both sides; but in the best doweled work the outer edge only is nailed, by driving the brad through the edge of the board obliquely, without piercing its surface, which, when the work is cleaned off, appears without blemish.

2172. In laying the floor-boards, they are sometimes laid one after the other, or one is first laid, then the fourth, at an interval of something less than the united breadth of the second and third together. The two intermediate boards are then laid in their places with one edge on the edge of the first board and the other upon that of the fourth board, the two middle edges resting against each other, rising to a ridge at the joint. In order to force these boards into their places, two or three workmen jump upon the ridge till they have brought the under sides of the boards close to the joints; they are then fixed in their places with brads. This method is that first mentioned under this head, and in it the boards are said to be folded. We have here mentioned only two boards, but four boards are most commonly folded at a time, and the mode is always resorted to when a suspicion exists that the boards are not sufficiently seasoned, or they are known not to be so. The headings of these folds are either square, splayed, or ploughed and tongued. If a heading occurs in the length of the floor, it should be invariably made to fall over a joist, and one heading should not meet another.

2173. In doweled floors the dowels should be placed over the middle of the interjoint rather than over the joists, so that the edge of one board may be prevented from passing that of the other. When the boards are only bradded upon one edge, the brads are concealed by driving them in a slanting direction through the outer edge of every successive board, with piercing the upper surface. In adzing the under sides of floor-boards opposite each joint, great care should be taken to clip away the stuff straight, and also to avoid taking away more of the stuff than is necessary, in which case the soundness of the floor will not be compromised.

#### FRAMING.

2174. In *fig. 781.* are shown several methods for framing angles in dadoes, skirtings, troughs, and other objects, whereof A exhibits the method of mitring dado on exterior angles in an apartment. In fixing this together, brads may be driven from each side. B is a method of framing used for troughs or other rectangular wooden vessels. C is a method of putting dado or skirting together at any interior angle of a room. This mode

is also employed for water-trunks, or troughs. In D is shown the manner of fixing and finishing two pieces of framing together, with a bead at their meeting, by which the joint is concealed. It is used only in common finishings. In those of a better sort the angle is kept entire, and only a three-eighth bead used at the joint, the angle being kept entire. It is a great point in all joiner's work to preserve the sharpness of the angles of the work, and many prefer the method shown in F, without any bead at the joint. In this the joint is made as close as possible, and is well glued together. If additional strength be required, blockings may be glued in the interior angle, which will make it quite firm. The method, by a simple mitre at E is not so good as at A, because it has no abutment.

2175. When it is required to glue up large work, those edges which are to receive the glue should be well warmed at a fire, and then, while warm, and the glue as hot as possible, they should be united, inasmuch as glue never holds well when it is chilled or cold.

Fig. 781.

## STAIRS.

2176. Stairs and their handrails are among the most important objects of the joiner's skill. The choice of situation, the design, and what suits the general convenience of the building, sufficiency of light, and easy ascent, are indeed matters for the exercise of the architect's talent; but all these, however well contrived and arranged, are incomplete without a clear and accurate execution of the work.

2177. There are some leading principles which are common to all staircases, of whatsoever materials they may be constructed. Thus it is a maxim that a broad step should be of less height than one which is narrower; and the reason is sufficiently obvious, because in striding, what a man loses in breadth he can more easily apply in raising himself by his feet. Now, as in common practice it is found that the convenient rise of a step 12 inches in width is  $5\frac{1}{2}$  inches, it may be assumed as some guide for the regulation of other dimensions. Thus  $12 \times 5\frac{1}{2} = 66$ , which would be a constant numerator for the proportion. Suppose, for instance, a step 10 inches in breadth, then  $\frac{66}{10} = 6\frac{3}{5}$  inches would be the height; and this agrees very nearly with the common practice. The breadth of steps in the commonest staircase may be taken at 10 inches at a medium. In the best staircases the breadth of the step should not be less than 12 inches, neither should it be more than 18 inches. (See 2814.)

2178. Having adjusted the proportions of the steps, our next consideration is to ascertain the number of risers which will be necessary to carry us from one floor to another. Suppose, for example, the height from the top of one floor to that of the next be 15 ft. = 180 in.; here, if the steps are each of 6 inches rise, we have  $\frac{180}{6} = 30$ , which is the number of risers necessary to ascend from floor to floor. If the height divided by the rise of each step should not give an exact number of risers, it is better to add one rather than diminish the number. Thus, suppose the distance from floor to floor to be 13 ft. 2 in. = 158 in., then  $\frac{158}{6} = 26\frac{1}{3}$ . Here it would be better to take 27 risers, for the steps must be equal in height.

2179. The width of the better sorts of staircases should not be less than 4 feet, to allow of two persons freely passing each other; but the want of space in town houses often obliges the architect to submit to less in what is called the *going* of the stair.

2180. The parts of every step in a staircase are one parallel to the horizon, which is called the *tread* of the step, terminated on the edge by a moulded or rounded *nosing*, and the other perpendicular to the horizon, which is called the *riser* of the step.

2181. It is not our intention to detail more than will be necessary for comprehending the work of the joiner in its application to stairs, which have many varieties of structure, dependent on the character, situation, and destination of the building. To this end we shall now, therefore, describe the method of carrying up *dog-legged*, *bracket*, and *geometrical* stairs.

2182. A *DOG-LEGGED STAIRCASE* is one which has no opening or well-hole, and in which the rail and balusters of the progressive and returning flights fall in the same vertical planes. The steps in it are fixed to strings, newel, and carriages, the ends of the steps of the inferior kind terminating only upon the side of the string without any housing. Y and Z in *fig. 782*. are the plan and elevation of a staircase of this kind; AB is the lower newel whereof the part BC is turned. On the plan, a is the seat of this newel. DE and FG in Y are the lower and upper string boards framed into newels. KL is a joist framed into the trimmer I. The lines on the plan represent the faces of the steps in the elevation without the nosings. MO and FQ are called the upper and lower ramps, the method of drawing

which is as follows: — In the upper ramp, for example, produce the top of the rail HM to P; draw MN vertical, and produce the straight part ON of the pitch of the rail to meet it in N, making NO equal to NM. Draw OP at a right angle to ON. From P, as a centre, describe the arc MO, and then the other contrary curve, which will complete the ramp required. The *story rod* RS is in the fixing of all staircases a necessary instrument; for in fixing the steps and other work by a common measuring rule, bit by bit, the chances are that an excess or defect will occur, to make the staircase faulty; which cannot be the case if the story rod is applied to every riser, and such riser be regulated thereby.

2183. A **BRACKET STAIRCASE** is one which has an opening or well, with strings and newels, and is supported by landings and carriages. The *brackets* are mitred to the end of each riser, and fixed to the string board, which is usually moulded like an architrave. In this sort of staircase the same methods are to be observed in respect of dimensions and laying off the plan and section as in a dog-legged staircase. Nothing is to be done without the story rod just described, which must be constantly applied in making and setting up the stairs. The method of forming the ramps and knees has been touched upon in the preceding article, and the few particulars we intend to give respecting scrolls and handrailing will be reserved for a subsequent page. In bracket stairs the internal angle of the steps is open to the end, and not closed by the string, as in common dog-legged stairs; the neatness also of the workmanship is as much attended to as in geometrical stairs. The balusters should be nicely dovetailed into the ends of the steps by twos, and the face of each front baluster is to be in a plane with the front face of the riser, and all the balusters being equally divided, the face of the middle one must of course stand in the middle of the face of the riser of the preceding step. The treads and risers are previously all glued up and blocked together, and when put in their places the under side of the step is nailed or screwed into the under edge of the riser, and then rough bracketed to the strings, as in a dog-legged staircase, in which the pitching pieces and rough strings are similar.

2184. A **GEOMETRICAL STAIRCASE** is one whose opening is down its centre, or, as it is called, an open newel, in which each step is supported by one end being fixed in the wall or partition, the other end of every step in the ascent having an auxiliary support from that immediately below it, beginning from the lowest one, which, of course, rests on the floor. The steps of a geometrical staircase should, when fixed, have a light and clean appearance, and, for strength's sake, the treads and risers, when placed in position, should not be less than  $1\frac{1}{2}$  inch thick, supposing the going of the stair or length of the step to be 4 feet. For every 6 inches in length of the step an eighth of an inch should be added. The risers should be dovetailed into the cover, and in putting up the steps, the treads are screwed up from below to the under edges of the risers. The holes for sinking the heads of the screws ought to be bored with a centre bit and fitted closely in with wood well matched, so that the screws may be entirely concealed, and appear as a uniform surface without blemish. Brackets are mitred to the risers, and the nosings are continued round; but this practice induces an apparent defect, from the brackets, instead of giving support, being themselves unsupported, and actually depending on the steps, being indeed of no other use than merely tying together the risers and treads of the internal angles of the steps; and from the internal angles being hollow, except at the ends, which terminate by the wall at one extremity, and by the bracket at the other, there is an appearance of incomplete finish. The cavetto or hollow is carried all round the front of the slip, returned at the end, and again at the end of the bracket, thence along the inside of it, and then along the internal angle at the back of the riser.

2185. The ancient mode, however, was the best, in which the wooden was an imitation of the method of constructing geometrical stairs in stone, which will be found under *Masonry*, in the previous Section III.; that is to say, the making of the steps themselves solid, and in section of the form of a bracket throughout their length. This is a more expensive method, but it is a solid and good one, and is still practised on the Continent, especially in France.

Fig. 782.

2186. In *fig. 783*. X is the plan and Y the elevation, or rather section, of a geometrical staircase. AB in X is what is called the *cur-tail step* (curved like the tail of a cur dog), which must be the first step fixed. CCC are the *flyers* supported from below by rough carriages, and partly from the string board DHEF in Y. The ends next the wall are sometimes housed into a notch board, and the steps then are made of thick wood and no carriages used. GGG are *winders* fixed to bearers and pitching pieces, when carriages are used to support the flyers. The winders are sometimes made of strong stuff firmly wedged into the wall, the steps screwed together, and the other ends of the steps fixed to the string DEHF.

Fig. 783.

Fig. 784.

In all cases of wooden geometrical stairs their strength may be greatly augmented by a flat bar of wrought iron coinciding with the under side and screwed to the string immediately below the steps. HIK in Y is the wall line of the soffit of the winding part of the stairs, and LMN part of the rail supported by two balusters upon every step. Where the space of the going of the stairs is confined, the French have long since introduced, as in *fig. 784*., the practice of placing the balusters outside the steps, which affords more room for persons ascending and descending.

## HANDRAILS AND CUR-TAIL STEP.

2187. The upper part of the fence formed by capping the balusters of stairs is called the *handrail*, whose use, as its name imports, is for a support to the hand in the ascent and descent of stairs. The hand, for support to the body, should glide easily over it without any strain, whence it is evident, that to be properly formed, it must necessarily follow the general line of the steps, and be quite smooth and free from inequalities. It must be obvious to the reader who has thus far followed us throughout the different previous portions of our labours, that the chief principle of handrailing will be dependent on the methods of finding sections of cylinders, cylindroids, or prisms, according to three given points in or out of the surface, or, in other words, the section made by a plane through three given points in space. The cylinder, cylindroid, and prism are hollow, and of the same thickness as the breadth of the rail, or the horizontal dimension of its section; and their bases, their planes or projections on the floor. Thus is formed the handrail of a staircase of a portion of a cylinder, cylindroid, or prism whose base is the plane of the stair, for over this the handrail must stand, and is therefore contained between the vertical surface of the cylinder, cylindroid, or prism. As the handrail is prepared in portions each whereof stands over a quadrant of the circle, ellipse, or prism of the base which forms the plane, such a portion may be supposed to be contained between two parallel planes, so that the portion of the handrail may be thus supposed to be contained between the cylindrical, cylindroidal, or prismatic surfaces and the two parallel planes. The parts to be joined together for forming the rail must be so prepared that in their place all the sections made by a vertical plane passing through the imaginary solid may be rectangular: this is denominated *squaring the rail*, and is all that can be done by geometrical rules. But handrails not being usually made of these portions of hollow cylinders or cylindroids, but of plank or thicknesses of wood, our attention is naturally drawn to the consideration of the mode in which portions of them may be formed from planks of sufficient thickness. The faces of the planks being planes, they may be supposed to be contained between two parallel planes, that is, the two faces of the plank. Such figures, therefore, are to be drawn on the sides of the plank as to leave the surfaces formed between the opposite figures, portions of the cylindrical, cylindroidal, or other surfaces required, when the superfluous parts are cut away. A mould made in the form of these figures, which is no more than a section of them, is called the *face mould*.

2188. The vertical, cylindrical, or prismatic surface being adjusted, the upper and lower surfaces must be next formed; and the cylindrical, or prismatic surface round the edge of such mould. The

superfluous wood is then cut away from top to bottom, so that if the piece were set in its place, and a straight line drawn on the surface of the wood, and parallel to the horizon directed to the axis of the well-hole, it would be necessary to lay down

A and B of the figure, are sections of the rail and mitre cap of a dog-legged staircase. Vertical lines are let fall from the section of the rail A, to the mitre in B; from thence, in arcs of circles, to the straight line passing through the centre of the cap at right angles to the former straight lines; then perpendiculars are set off and made equal in length to those in A.

A curve being traced through the points gives the form of the cap. C is called a *toad's back rail*, and is used for a superior description of staircases.

2190. Fig. 786. shows the method of drawing the scroll for terminating the handrail at the bottom of a geometrical staircase. Let AB be the given breadth; draw AE perpendicular to AB, which divide into eleven equal parts, and make AE equal to one of them. Join BE, bisect AB in C and BE in F. Make CD equal to CF and draw DG perpendicular to AB. From F, with the radius FE or FB, describe an

Fig. 785.

Fig. 786.

are cutting DG at G. Draw GH perpendicular to BE cutting BE at O. Draw the diagonals DOK and IOL perpendicular to DOK. Draw IK parallel to BA; KL parallel to ID, and so on to meet the diagonals. From D as a centre, with the distance DB, describe the arc BG. From I as a centre, with the distance IG, describe the arc GE. From K as a centre, with the distance KE, describe the arc EH. From L as a centre, with the distance LH, describe the arc HP. Proceed in the same manner and complete the remaining three quarters, which will finish the outside of the scroll. Make BR equal to the breadth of the rail; namely, about two inches and a quarter. Then with the centre D and distance DR describe the arc RS, with the centre I and distance IS describe the arc ST, and with the centre T and distance KT describe the arc TU, and the scroll will be completed.

Fig. 787.

Fig. 788.

2191. Fig. 787. gives the construction of the cur-tail step, or that which lies under the scroll, *abcd* is the veneer that covers the riser; *efgh*, the nosing of the cover or horizontal part of the step; *ikl* the face of the string board, and *mno* the projection of the nosing.

2192. In *fig. 788.* is shown the cover board for the cur-tail step, *abcd* and *efgh* in dotted lines represent the plan of the scroll; *opqrs*, the nosing of the curtail step; *t, u, v, s*, the nosings and ends of the risers. The circle 1, 2, 3, &c. is described from the centre of the scroll, and divided into equal parts equal to the distances of the balusters from centre to centre, and lines are drawn to the centre of the scroll in order to ascertain the middle of the balusters, by giving a regular gradation to the spaces. The whole of the spiral lines in this and the previous figure are drawn from the same centres as the scroll.

#### FORMATION OF BODIES BY JOINING THEM WITH GLUE.

2193. The way in which bodies are glued up together for different purposes will be given below, and with them will close this section.

2194. *Fig. 789.* shows at A a section of two boards glued up edge to edge. At B the face of the same is seen. C shows the section of two boards glued edge to edge, each piece being grooved, and a *tongue* inserted at their junction. By similar means a board may be increased to any width, be the pieces whereof it is composed ever so narrow. D shows two boards fixed at right angles, the edge of one being glued on the side of the other. A block for the purpose of strengthening the joint is fitted and glued to the interior side.

Fig. 789.

Fig. 790.

2195. *Fig. 790.* A is a section of two boards to be joined at an oblique angle. They are mitred and glued together with a block at the angle. B shows the inner sides of the boards so fixed. It is by repeating this operation that columns are glued up.

2196. *Fig. 791.* A is the section of an architrave. The moulding is usually, if not always, glued to the board; the vertical line therefore, showing the extreme boundary of the moulded part, is the section of the piece to be glued, B is the face of the architrave, C and D a section and front of it before it is moulded, E a section of it with the button and nail to show the way in which the two parts are glued together, and F shows the back of the architrave with the buttons which are used for the purpose of bringing the two surfaces to be glued together in contact, till after they are set and fully held together, being knocked off when the glue has become hard, and then the moulding shown at A and B is stuck.

Fig. 791.

2197. *Fig. 792.* exhibits the method of gluing up a solid niche in wood where A is the elevation. The work is performed in the same way as if it were stone or brick, except that the joints are all parallel to the plane of the base, because of the difficulty of making a joint with curved surfaces, which would necessarily be the case if they all tended to the centre of the sphere. B and C are the two bottom courses, where the vertical joints are made to break, as seen in the elevation A.

Fig. 792.

Fig. 793.

Fig. 794.

2198. In *fig. 793.* is exhibited the mode in which veneers are glued together for the purpose of forming cylindrical surfaces. Brackets with their faces upwards are nailed to

a board. Their ends are perpendicular, and a cavity is left between them sufficient to receive the veneers and wedges. In A the thin part in the form of an arc shows the veneers as in the state of glueing, the wedges being on the convex side. B is a section of the board and bracket. The work when putting together should be dry and warm, and the glue should be hot. When this last has set hard, the wedges must be slackened, and the veneers, which now form a solid, taken out.

2199. *Fig. 794.* is a strong method of forming a concave surface by laying the veneer upon a cylinder, and backing it with blocks in the form of bricks, which are glued to the convex side of the veneers and to each other. The fibres of the blocks are to be as nearly as possible parallel to the fibres of the veneers. A is the section of the cylinder veneer and blocks, and B shows the convex side of the blocks.

2200. *Fig. 795.* is another mode of glueing veneers together with cross pieces screwed to a cylinder, the veneers being placed between the former and the latter.

Fig. 795.

Fig. 796.

Fig. 797.

2201. In *fig. 796.* is shown the method of glueing up columns in pieces, which here are eight in number, each being glued to the other after the manner of *fig. 790.* The workman should be careful to keep the joints out of the flutes, when the columns are to be fluted, by which the substance will be more likely to prevent the joints giving way. A is a section of the column at top, and B at the bottom. After glueing together, the octagons and mitres should be correctly laid down for the true formation of the joints. In B are shown two bevels, one for trying the mitres, and the other for trying the work when put together.

2202. *Fig. 797.* is the mode of glueing up the base of a column. It is formed in three courses, the pieces in each of which are made to break joint over one another. The horizontal joints of the courses must be so adjusted as to fall at the junction of two mouldings, forming a re-entering angle. After the glue is set quite hard, the rough base is sent to the turner, by whom it is reduced into the required profile. The fibres of the wood should be horizontally, in which direction the work

Fig. 798.

Fig. 799

will stand much better than when they are vertical. A is the plan of the base inverted, and B is the elevation.

2203. The formation of a modern Ionic capital is given in *fig. 798.*, wherein A is the plan inverted, showing the method of placing the blocks; and B is the elevation.

2204. *Fig. 799.* is the method of glueing up for the leaves of the Corinthian capital, A is the plan inverted, and B is the elevation. The abacus is glued up in the same manner as in the preceding example.

Fig. 800.

Fig. 801.

Fig. 802.

2205. *Fig. 800.* exhibits the mode of forming a cylindrical surface without veneers, by means of equidistant parallel grooves, A is the elevation, and B the plan.

2206. *Fig. 801.* exhibits the method of covering a conic body. It is, in fact, no more than covering the frustum of a cone, and is accomplished by two concentric arcs terminated at the ends by the radii. The radius of the one arc is the whole slant side of the cone, that of the other is the slant side of the part cut off. In this case, the grooves are directed to the centre, and filled in with slips of wood glued as before. The plan is shown by the circle ABC. The arc HI must be equal to the circumference ABC.

2207. *Fig. 802.* shows the same thing for a smaller segment.

2208. *Fig. 803.* shows the manner of glueing up a globe or sphere by the same method. A is the face of the piece; B the edge showing the depth of the grooves; C shows the mould for forming the piece to the true curvature; and D the faces of two pieces put together.

Fig. 803.

## SECT. VI.

## SLATING.

2209. An account of the materials used by the slater have been detailed in Chap. II. Sect. IX., and will not leave us much to say on their application.

2210. The tools used by this artificer are the *scantle*, which is a gauge by which slates are regulated to their proper length; the *trowel*; the *hammer*; the *zax*, an instrument for cutting the slates; a small *handpick*, and a *hod and board* for mortar.

2211. Slating is laid in inclined courses, beginning from the eaves and working upwards, the courses nearest the ridge of the roof being less in width than those below. The *lap* of one slate over another is called its *bond*, and it is the distance between the nail of the under slate and the lower end of the upper slate. The *bed* of a slate is its under side, and the upper side is called its *back*. The part of each course which is exposed to the weather is called its *margin*. The slates are nailed to close or open boarding lying on the back of the rafters with nails, which should be of copper or zinc. If iron nails are used they should be well painted. The operation of cutting or paring the side and bottom edges of the

slates is called *trimming* them; but the head of the slate is never cut. In that part holes are pierced through the slates by which the nails pass to the boarding. The operations of the slater are of so simple a nature, that we do not further think it necessary to detain the reader on this section, which, with that of Sect. IX. Chap. II. in this Book, affords all the information that can be required.

## SECT. VII.

### PLUMBERY.

2212. The plumber has but few working tools, for the facility with which the metal in which he works is wrought does not render a variety necessary. The principal are — a heavy iron *hammer*, with a short but thick handle. Two or three different sized *wooden mallets*, and a *dressing and flattening tool*, which is made of beech wood, usually about 18 inches long and  $2\frac{1}{2}$  inches square, planed smooth on one side, and rounded on the other or upper side. It is tapered and rounded at one of its ends for convenient grasping by the workman. Its use is to stretch and flatten the sheet lead, and dress it into the shape required for the various purposes whereto it is to be applied, by the use of its flat and round sides as wanted. The *jack and trying planes*, similar to those used by carpenters, for planing straight the edges of their sheet lead when a regular and correct line is requisite. They also use a line and roller called a *chalk line*, for lining out the lead into different widths. Their cutting tools are *chisels* and *gouges*, of different sizes, and *cutting knives*. The latter are for cutting the sheet lead into strips and pieces to the division marked by the chalk line. They use also *files* of different sizes for making cistern heads to pipes, for pumpwork, &c. For the purpose of soldering, they have a variety of different sized *grozing irons*, which are commonly about 12 inches long, tapered at both ends, the handle end being turned quite round to allow of its being held firmly in the hand whilst in use. The opposite end is spherical, or more usually spindle-shaped, and proportioned to the different situations for which they are required. The grozing iron is heated to redness when in use. The *iron ladders* are of three or four sizes, and used for the purpose of melting lead or solder. The plumber's *measuring rule* is 2 feet long, in three parts, each of 8 inches. Two of the legs are of box-wood, and the third of steel, which is attached to one of the box legs by a pivot whereto it turns, and shuts into the other legs in a groove. The steel leg is useful for passing into places which the plumber has to examine, into which anything thicker would not easily enter, and it is often used also for removing oxide or other extraneous matter from the surface of the heated metal. The plumber moreover is provided with *centre bits* of all sizes, and a stock to work them in, for perforating lead or wood where pipes are to be inserted, as well as with compasses, for striking out circular portions of lead. *Scales and weights* are also in constant requisition, as nothing done by the plumber is chargeable till the lead is weighed.

2213. The method most commonly adopted in laying sheet lead for terraces or flats, is to place it on a surface as even as possible, either of boarding or plastering. If boards are employed, they should be sufficiently thick to prevent warping or twisting, which, if it occur soon, causes the lead to crack or to become unsightly. As sheets of lead are not more than about 6 feet in width, when the area to be covered with them is large, joints become necessary, which are contrived in various ways to prevent the wet from penetrating. To do this, the best method is that of forming *rolls*, which are pieces of wood about 2 inches square extending in the direction of the joint, planed and rounded on their upper side. These being fastened under the joints of the lead between the edges of the two sheets which meet together, one is dressed up over the roll on the inside, and the other over both of them on the outside, whereby all entry of the water is prevented. No fastening is required other than the adherence of the lead by close hammering together and down on the flat: indeed, any fastening would be injurious, as by it the lead would not have free play in its expansion and contraction from heat and cold. If rolls are not employed, which from their projection are in some cases found inconvenient, *seams* are substituted for them; but they are by no means equal to the roll either for neatness or security. They are formed by merely bending up the two edges of the lead, and then over one another, and then dressing them down close to the flat throughout their length. Though some solder the joints, it is a bad practice, and no good plumber will do it, for the same reason as that just given in respect of fastenings in flats. A leaden flat, as well as a gutter, should be laid with a fall to keep it dry. A quarter of an inch in a foot is sufficient inclination for lead, if the sheets be 20 feet long, so that in this case they will be 5 inches at one end higher than at the other. This *giving a current*, as it is called, is usually provided for by the carpenter previous to laying the lead.

2214. Round the extreme edges of flats and gutters where lead is used, are fixed pieces

of milled lead which are called *flashings*. When the lead work is bounded by a wall of brick or stone work, the flashings are passed on one edge into and between a joint of the work, and the edges of the flat or gutter being bent up, the other edge of the flashing is dressed over it. If there be no joint into which the flashing can be inserted, it is fastened on that side with wall hooks. *Drips* in flats and gutters are used when the length of the gutter or flat is greater than the length of the sheet of lead, or sometimes for convenience, or to avoid joining lead by soldering it. They are formed by raising one part above another, and dressing the lead round, as has been described for rolls.

2215. The pipes used for the purposes of building are proportioned to their uses. Those, for instance, for carrying away the soil from a water closet, or the conveyance of water from roofs and sinks, are of course of larger diameter than those called *service pipes*, which are merely, as their name implies, for laying on water.

TABLE OF THE WEIGHT OF LEADEN PIPES.

Pipes of $\frac{3}{4}$ -inch bore weigh per yard	10 lbs.
Pipes of 1-inch bore	— 12 lbs.
Pipes of $1\frac{1}{4}$ -inch bore	— 16 lbs.
Pipes of $1\frac{1}{2}$ -inch bore	— 18 lbs.
Pipes of $1\frac{3}{4}$ -inch bore	— 21 lbs.
Pipes of 2-inch bore	— 24 lbs.

2216. The work of the plumber is estimated by its weight and the time employed in fixing it. The weights and thicknesses of different sizes of sheet lead have been already given in Chap. II. Sect. VI. of this Book.

2217. The lead generally used in roofing and guttering is from 7 to 12 lbs. to the superficial foot, and great vigilance on the part of the architect is required, in these days of contracts, to see that his employer has the thickness, or, which is the same thing, the weight that has been contracted for.

2218. We do not think it necessary to describe at length the machinery of a water closet. Every one knows that the principle on which it is formed is that of a head of water in a cistern placed above it, which by means of a lever attached to a valve in the cistern allows a body of water to rush down and wash the basin, whose valve is opened for the discharge of the soil at the same moment that the water is let down from the cistern. Various instruments for this purpose have been contrived and patented, but we are not aware of any better than those which were made by the late Mr. Bramah, almost as soon as the subject formed a matter of inquiry. The reader will obtain by the inspection of one a far better notion than words or diagrams will convey.

2219. As it is a branch of the plumber's trade to find and fix the pumps for the supply of water to a dwelling, we think it right to furnish a description of the three sorts commonly used, which are the *lifting*, the *common*, and the *force pump*.

2220. Fig. 804. is a diagram of a lifting pump, in which ABCD is a short cylinder submerged in the well or other reservoir, whence the water is to be raised. In this cylinder a valve is placed at *x*, above which the pipe or tube CE is carried upwards as high as is requisite for the delivery of the water. In the cylinder AD a water-tight piston moves vertically, being worked by rod or framework as seen in the diagram. To this piston is fixed a valve at *v* opening upwards. On the descent of the piston the pressure against the water opens the valve *v*, and the cylinder between the two valves is filled with the water. When the piston is then raised, the water between the valves being pressed upwards against the valve *x*, opens it, and is driven into the tube CE, from which, on the renewed descent of the piston, its return is intercepted by the valve *x*. The water follows the piston in its ascent by the hydrostatic pressure of the water in the reservoir outside the cylinder; and on the next descent of the piston the water will again pass through the valve *v*, and will be driven through the valve *x* on its next ascent. It is manifest from inspection that the valve *x* relieves the valve *v* from the pressure of the column of water in the tube CE during the descent of the piston; for if the valve *v* were subject to that pressure during the descent of the piston, it could not be opened by the pressure of the water in the well, inasmuch as its level is necessarily below the level of the water in the pipe CE. The valve *v* prevents the return of the water through the piston during its ascent. In raising the piston a force is required sufficient to support the entire column of water from the valve *v* to the surface of the water in the tube CE. To estimate this, we must take the weight of a column of water whose base is equal to the area of a section of the piston,

Fig. 804.

and whose height is equal to that of the surface of the water above the valve  $v$  in the tube CE. Hence, after each stroke of the pump, the pressure on the piston and the force necessary to raise it, will be increased by the weight of a column of water whose base is the horizontal section of the piston, and its height equal to the increase which the elevation of the column in CE receives from the water driven through the valve  $x$ . In the figure  $cd$  is the piston, the bottom of whose rod is at  $b$ ;  $m$  and  $n$  are rods which connect it with the upper part of the work, and WW is the level of the water in the well.

2221. The common, or as it is usually called, *suction pump* (shown in *fig. 805.*), is nothing more than a large syringe connected with a tube whose lower extremity is plunged in the well from which the water is to be raised. The tube is called a *suction pipe* (SO), and its end in the well is represented by O, which, for the purpose of preventing the ascent of solid impurities, that might choke the pipe and impede its action, is pierced with holes like a strainer. At the upper end of this suction pipe is placed the valve  $x$  opening upwards. At this place the tube is connected with another, BC, which acts as a great syringe, and in which works a piston having a valve at  $v$ , also opening upwards. The piston is worked alternately upwards and downwards in common pumps by a lever called the *brake*, but it may be worked in many ways. In the figure, W is the level of the water, CD the *flange*, where the lower valve is fixed,  $cd$  the piston,  $ab$  the piston rod, and MN the cistern into which the water is raised and delivered by its gravity at the nozzle of the pump  $e$ . At the commencement of the operation the water in the suction tube stands at the same height as the water in the well, being equally subject to the atmospheric pressure; but as soon as the syringe BC exhausts the air by the upward and downward action of the piston  $cd$ , the pressure of the air in SO being diminished and rendered less than that on the surface of the water in the well, will rise in SO by the atmospheric pressure; and as the air becomes more completely exhausted in the column of water in the tube SO below the valve  $x$ , so will its pressure on the surface of the column be diminished, and whilst that diminution goes on, the height of the column will increase. If the air could be entirely withdrawn from the tube SO, and a perfect vacuum created beneath the valve  $x$ , similar to that existing above the mercury in a barometer, then the atmospheric pressure, acting with undiminished effect on the surface of water in the well, would, in the tube SO, sustain a column of water equal to a column of mercury of the same base and of the same height as the mercury in the barometer. Now, the specific gravity of mercury being  $13\frac{1}{2}$  times greater than that of water, a force capable of sustaining a column of mercury 30 inches high, would sustain a column of water equal to  $30 \text{ inches} \times 13\frac{1}{2} = 405 \text{ inches} = 33\frac{3}{4} \text{ feet}$ . But an absolute vacuum is never formed, and, moreover, in this country, as the barometric column varies between 28 and 31 inches in height, the valve  $x$  should on no account be more than 28 feet above the level of the water in the well, taking into consideration all the attendant circumstances.

This is the construction and principle upon which the common household pump is formed, and in it no other aid is derived from atmospheric pressure than what we have already stated; hence the pump requires as much force to work it as, in general terms, is equal to the weight of all the water in it at any time, the atmospheric pressure affording no aid to the workman. The cistern at the top is placed for the purpose of affording an unintermitted discharge of the water by holding more than the whole accumulation of water which is contrived to be greater than the spout or nozzle will discharge.

2222. The forcing pump, whose construction is shown in *fig. 806.*, is a combination of the common suction and lifting pump. CEFD is a suction pipe descending into the well, and at its top is the valve V opening upwards. The pump barrel ABCD is furnished with a solid piston  $cd$ , whose rod is  $ab$ , without any valve. From the side of the barrel, just above the suction valve, a pipe proceeds, communicating with an upright cylinder GH, carried to such height as the water is intended to be raised. At the bottom of this cylinder is placed the valve V' opening upwards. At the commencement of working, the suction pipe CE and the chamber between the piston and valves are filled with air. When the piston descends to the valve V, the air enclosed in the latter chamber becomes condensed, and opening,

Fig. 805.

Fig. 806.

therefore, the valve *V'*, a part of it escapes through it. On raising the piston the air below it becomes partially exhausted, and that in the suction pipe, opening the valve *V*, by its greater pressure, expands into the upper chamber. A part of this is expelled when the piston next descends, by means of the valve *V'*. This action is similar to that of an air pump or exhausting syringe. When by the repetition of this action the air is sufficiently exhausted, the atmospheric pressure upon the water in the well causes the water to rise therefrom through the suction pipe and the valve *V*, into the chamber between the piston and the valves. When the piston next descends it presses on the surface of the water, and the valve *V* closing prevents the return of the water into the suction pipe, while the pressure of the piston being transmitted by the water to the valve *V'*, opens it, and as the piston descends, the water passes into the force pipe *GH*. On the next ascent of the piston more water is allowed to pass through the valve *V*, and the next descent forces this water through the valve *V'* into the force pipe. By repeating the action the quantity of water in the force pipe increases, receiving equal additions at each descent of the piston. It is obvious that the position of the force pipe is a matter of no moment; it may be perpendicular, oblique, or horizontal; for in each case the water will be propelled through it. When the piston is pressed downwards, and the valve *V'* is opened, it is necessary that the force working the piston should balance the weight of the column of water in the force pipe, for this weight is transmitted by the water between the piston and force pipe to the bottom of the piston; the height, therefore, of the column of water in the force pipe will measure the intensity of the pressure against the base of the piston when the valve *V'* is open. A column of water suspended 34 feet in height in the force pipe will press on the base of the piston with a force of about 15 pounds for each square inch; and the pressure at other heights will be proportional to this. Thus the force necessary to urge the piston downwards may always be calculated. The valve *V'* is closed in drawing up the piston, and it then relieves the piston from the weight of the incumbent column. If the valve *V* is opened, the piston is subject to the same pressure as in the suction pump, and this has already been seen to be equal to the weight of a column of water raised above the level of the water in the well. From this it follows, that when the height of the force pipe is equal to the length of the suction pipe, the piston will be pressed upwards and downwards with equal forces; but when the height of the force pipe is greater or less than the length of the suction pipe, the downward pressure must be greater or less, in the same proportion, than the force which draws the piston up.

2223. The supply of water by the force pipe through the valve *V'* is evidently intermittent, being suspended during the ascent of the piston; hence the flow from the point of discharge will be subject to the same intermission if means be not taken to counteract such effect. A cistern at the top of the force pipe, as already shown, for the suction pump, would answer the purpose; but it is found more convenient to use an apparatus called an *air vessel* (see *fig. 807.*), in which immediately above the valve *V'* a short tube communicates with a strong close vessel of sufficient capacity, through the top whereof the force pipe *GH* passes, and descends to near the bottom. When the pump is in action the water is forced into the vessel *MN*, and when its surface, as at *ww*, rises above the mouth *H* of the force pipe, the air in the vessel *MN* is confined above the water; and as the water is gradually forced in, the air, being compressed, acts with increased elastic force on the surface of the water. This pressure forces a column of water into the pipe *HG*, and maintains it at an elevation proportional to the elastic force of the condensed air. When the air in the vessel *MN* is reduced to half its original bulk it will act on the surface of the water *ww* with double the atmospheric pressure; meanwhile, the water in the force pipe being subject to merely once the atmospheric pressure, there is an unresisted force upwards equal to the atmospheric pressure which sustains the column of water in the tube, and a column 34 feet high will thus be sustained. If the air is reduced to one third of its original bulk, the height of the column sustained will be 68 feet, and so on. If the force pipe were made to terminate in a ball pierced with small holes so as to form a *jet d'eau*, the elastic pressure of the air on the surface would cause the water to spout from the holes.

Fig. 807.

2224. In the formation of all pumps the parts should be nicely fitted, and as air-tight as possible, otherwise, in using them, much of the power employed will be lost. All expedients which tend to this great desideratum are of value; indeed any arrangement adapted to insure the perfect action of a pump is of the utmost importance for the comfort and convenience of small no less than large dwellings.

## SECT. VIII.

## GLAZING.

2225. Glazing, or the business of the glazier, consists in fitting glass in sashes, frames, and casements, either in putty or lead. It may be classed under the heads of *sashwork*, *leadwork*, and *fretwork*. Glass, as a material, has been already described in Chap. II. Sect. II. of this Book.

2226. The tools necessary for sashwork are—a *diamond*, polished to a cutting point, and set in brass in an iron socket, to receive a wooden handle, by which it is held in a cutting direction. The top of the handle goes between the root of the forefinger and middle finger, and the under part between the point of the forefinger and thumb. In general, there is a notch on the side of the socket, which should be held next the lath. Some diamonds have more *cuts* than one. Plough diamonds have a square nut on the end of the socket next the glass, which, on running the nut square on the side of the lath, keeps it in the cutting direction. Glass benders have their plough diamonds without long handles, as they cannot make use of a lath in cutting, but direct them by the point of their middle finger. The ranging lath should be long enough to extend beyond the boundary of the table of glass. *Ranging* of glass is the cutting it in breadths, and is best done by one uninterrupted cut from one end to the other. A *short lath* is used for stripping the square to suit the rebate of the sash, as in ranging they are generally cut full. A *square*, for the more accurate cutting at the right angles from the range. The carpenter's chisel is used in paring away some of the rebate of the sash when the glass does not lie so flat as to allow a proper breadth for front putty. The *glazing knife* is used for laying in the putty on the rebates, for bedding in the glass, and finishing the front putty. A *bradding hammer* is made with a head in the form of a small parallelopiped, with a socket for the handle, using it at an obtuse angle from the middle of one of its sides. The square edges of the head drive the brads in a horizontal direction, and with this tool there is less liability to accident than with any other. Some use the basil of the chisel for the purpose. *Brass points* are considered the best for bradding; *small cut brads* are also used. All new work should be bradded, to prevent the glass being moved out of its bed. The *duster* is a large brush for brushing the putties, and taking the oil from the glass. The *sash tool* is used wet, for taking the oil from the inside after the back putties are cleared off. The *hacking knife* is for cleaning out the old putty from the rebates where squares are to be stopped in. The use of the *glazier's rule* needs no explanation: it is 2 feet long, doubling in four different pieces.

2227. Leadwork for lights is often used for inferior offices, and frequently in country buildings. Frames made with crossbars receive these lights, which are fastened with leaden bars, called saddle bars. Where springs are wanted, a casement is introduced of wood or iron. Sometimes a sliding frame is used, particularly for church windows.

2228. The tool called the *glazier's vice* is for preparing the leaden slips with grooves, &c., to fit them for the reception of glass. The German vices are esteemed the best, and turn out a variety of lead in different sizes. There are moulds belonging to these vices in which bars of lead are cast; in this form the mill receives them, and turns them out with two sides parallel to each other, and about  $\frac{3}{8}$  of an inch broad, and a partition connecting the two sides together, about  $\frac{1}{8}$  of an inch wide, forming on each side a groove near  $\frac{3}{16}$  by  $\frac{1}{8}$  of an inch, and 6 feet long. The *setting board* is that on which the ridge of the light is worked, and divided into squares, and struck out with a chalk line, or drawn with a lath, which serve to guide the workman. One side and end is squared with a projecting bead or fillet. The *latterkin* is a piece of hard wood pointed, and so formed as to clear the groove of the lead, and widen it, for the more readily receiving the glass. The *setting knife* is a blade with a round end, loaded with lead at the bottom of the blade, and having a long square handle. The square end of the handle serves to force the squares home tight in the lead; being loaded with lead, it is of greater weight, and also cuts off the ends of the lead with greater ease, as in the course of working these lights the lead is always longer than is necessary till trimmed.

2229. The resin box contains powdered resin, which is put on all the joints previous to soldering. *Clips* are for holding the irons. All the intersections are soldered on both sides except the outside joints of the outer side, that is, where they come to the outer edge. These lights should be cemented, which is done by thin paint being run along the lead bars and the chasm filled with dry whiting. After it has stood a short time a small quantity of dry red or white lead is dusted over it, which will enable it to resist the weather well. *Fretwork* is the ornamental part of lead-light work, and consists in working ground or stained glass into different patterns and devices, as may be seen in the old stained glass windows.

2230. In London a large portion of the glazier's business consists in cleaning windows.

2231. The putty in which the glazier beds the glass is of four sorts. *Soft putty*, which is composed of flour, whiting, and raw linseed oil; *hard putty*, composed of whiting and

boiled linseed oil; *harder putty*, the same ingredients as the last, with the addition of a small quantity of turpentine for more quickly drying it; *hardest putty*, composed of oil, red or white lead, and sand. The first of these putties is the most durable, because it forms an oleaginous coat on the surface, but it requires a long time for drying. The hard sorts are apt to crack if not soon well painted, and the hardest of them renders it difficult to replace a pane when broken; hence it is altogether unfit for hothouse and greenhouse work.

## SECT. IX.

## PLASTERING.

2232. In the finishing of our dwellings, the decoration owes much of its effect to the labours of the plasterer: it is in his department to lay the ceilings, and to give, by means of plaster, a smooth coat to the walls, so as to hide the irregularities left by the bricklayer and mason, and make them slightly and agreeable. He also, in the better sort of buildings, furnishes plain and decorated mouldings for the cornices and ceilings; and in the external parts, where stone is expensive or not to be procured, covers the exterior walls with stucco or other composition imitative of stone.

2233. The plasterer's tools are—a *spade* or *shovel* of the usual description; a *rake* with two or three prongs bent downwards from the line of the handle, for mixing the hair and mortar together; *stopping* and *picking out* tools; rules called *straight edges*; *wood models*; and *trowels* of two sorts and various sizes; namely, the *laying* and *smoothing tool*, consisting of a flat piece of hardened iron, about 10 inches long, and  $2\frac{1}{2}$  inches wide, very thin, and ground to a semicircular shape at one end, but square at the other. Near the square end on the back of the plate a small iron rod is riveted, with two legs, whereof one is fixed to the plate, and a round wooden handle is adapted to the other. All the first coats of plastering are laid on with this tool, as is also the last, or *setting*, as it is technically called. The other sorts of trowels are of three or more sizes, and are used for *guing* the *fine stuff* and plaster for cornices, mouldings, &c. The length of these trowels is, the largest about 7 inches in length on the plate, and the smallest 2 or 3 inches: they are of polished steel, converging gradually to a point, with handles of mahogany adapted to the heel or broad end with a deep brass ferrule.

2234. The stopping and picking out tools are of polished steel, of various sizes, about 7 or 8 inches long and half an inch broad, flattened at both ends, and somewhat rounded. They are used for modelling and finishing mitres and returns to cornices, as also for filling up and finishing ornaments at their joinings. There is also used a small instrument, which is a piece of thin fir 6 or 7 inches square, called a *hawk*, with a handle vertical to it, for holding small quantities of plaster.

2235. The composition used by the plasterer is a groundwork of lime and hair, on which, for the finish, a coating of finer material is laid. The sorts of it are various; as, for instance, white lime and hair mortar on bare walls: the same on laths as for partitions and plain ceilings; for renewing the insides of walls, roughcasting on laths; plastering on brickwork with finishing mortar, in imitation of stone work, and the like upon laths. For cornices and the decorations of mouldings, the material is plaster of Paris, one which facilitates the giving by casts the required form and finish to the superior parts of his work. The plasterer uses it also for mixing with lime and hair, where the work is required to dry and set hard in a short time. For inside work, the lime and hair, or *coarse stuff*, is prepared, like common mortar, with sand; but in the mixing, hair of the bullock, obtained from the tanners' yards, is added to it, and worked in with the rake, so as to distribute it over the mass as equally as possible.

2236. What is called *fine stuff* is made of pure lime, slaked with a small quantity of water, and afterwards, without the addition of any other material, saturated with water, and in a semi-fluid state placed in a tub to remain until the water has evaporated. In some cases, for better binding the work, a small quantity of hair is worked into the composition. For interior work, the fine stuff is mixed with one part of very fine washed sand to three parts of fine stuff, and is then used for *trowelled* or *bastard stucco*, which makes a proper surface for receiving painting.

2237. What is called *guinge stuff* is composed of fine stuff and plaster of Paris, in proportions according to the rapidity with which the work is wanted to be finished. About four-fifths of fine stuff to one of the last is sufficient, if time can be allowed for the setting. This composition is chiefly used for cornices and mouldings, run with a wooden mould. We may here mention that it is of the utmost importance, in plasterers' work, that the lime should be most thoroughly slaked, or the consequence will be blisters thrown out upon the work after it is finished. Many plasterers keep their stuffs a considerable

period before they are wanted to be used in the building, by which the chance of blistering is much lessened.

2238. When a wall is to be plastered, it is called *rendering*; in other cases the first operation, as in ceilings, partitions, &c., is *lathing*, nailing the laths to the joists, quarters, or battens. If the laths are oaken, wrought iron nails must be used for nailing them, but cast iron nails may be employed if the laths are of fir. The lath is made in three and four foot lengths, and, according to its thickness, is called *single*, something less than a quarter of an inch thick, *lath and half*, or *double*. The first is the thinnest and cheapest, the second is about one-third thicker than the single lath, and the double lath is twice the thickness. When the plasterer laths ceilings, both lengths of laths should be used, by which, in nailing, he will have the opportunity of breaking the joints, which will not only help in improving the general *key*, (or plastering insinuated behind the lath, which spreads there beyond the distance that the laths are apart,) but will strengthen the ceiling generally. The thinnest laths may be used in partitions, because in a vertical position the strain of the plaster upon them is not so great; but for ceilings the strongest laths should be employed. In lathing, the ends of the laths should not be lapped upon each other where they terminate upon a quarter or batten, which is often done to save a row of nails and the trouble of cutting them, for such a practice leaves only a quarter of an inch for the thickness of the plaster; and if the laths are very crooked, which is frequently the case, sufficient space will not be left to straighten the plaster.

2239. After lathing, the next operation is *laying*, more commonly called *plastering*. It is the first coat on laths, when the plaster has two coats or set work, and is not scratched with the scratcher, but the surface is roughed by sweeping it with a broom. On brick-work it is also the first coat, and is called *rendering*. The mere laying or rendering is the most economical sort of plastering, and does for inferior rooms or cottages.

2240. What is called *pricking up* is the first coat of three-coat work upon laths. The material used for it is coarse stuff, being only the preparation for a more perfect kind of work. After the coat is laid on, it is scored in diagonal directions with a *scratcher* (the end of a lath), to give it a key or tie for the coat that is to follow it.

2241. *Lath layed or plastered and set* is only two-coat work, as mentioned under laying, the setting being the guage or mixture of putty and plaster, or, in common work, of fine stuff, with which, when very dry, a little sand is used; and here it may be as well to mention, that *setting* may be either a second coat upon laying or rendering, or a third coat upon *floating*, which will be hereafter described. The term finishing is applied to the third coat when of stucco, but setting for paper. The setting is spread with the smoothing trowel, which the workman uses with his right hand, while in his left he uses a large flat-formed brush of hog's bristles. As he lays on the putty or set with the trowel, he draws the brush, full of water, backwards and forwards over its surface, thus producing a tolerably fair face for the work.

2242. Work which consists of three coats is called *float*: it takes its name from an instrument called a *float*, which is an implement or rule moved in every direction on the plaster while it is soft, for giving a perfectly plane surface to the second coat of work. Floats are of three sorts: the *hand float*, which is a short rule, that a man by himself may use; the *quirk float*, which is used on or in angles; and the *Derby*, which is of such a length as to require two men to use it. Previous to floating, which is, in fact, the operation of making the surface of the work a perfect plane, such surface is subdivided in several bays, which are formed by vertical styles of plastering, (three, four, five, or even ten feet apart,) formed with great accuracy by means of the plumb rule, all in the same plane. These styles are called *screeds*, and being carefully set out to the coat that is applied between them, the plaster or floating laid on between them is brought to the proper surface by working the float up and down on the screeds, so as to bring the surface all to the same plane, which operation is termed *filling out*, and is applicable as well to ceilings as to walls. This branch of plastering requires the best sort of workmen, and great care in the execution.

2243. *Bastard stucco* is of three coats, the first whereof is roughing in or rendering, the second is floating, as in trowelled stucco, which will be next described; but the finishing coat contains a small quantity of hair behind the sand. This work is not hand-floated, and the trowelling is done with less labour than what is denominated trowelled stucco.

2244. *Trowelled stucco*, which is the best sort of plastering for the reception of paint, is formed on a floated coat of work, and such floating should be as dry as possible before the stucco is applied. In the last process, the plasterer uses the hand float, which is made of a piece of half-inch deal, about nine inches long and three inches wide, planed smooth with its lower edges a little rounded off, and having a handle on the upper surface. The ground to be stuccoed being made as smooth as possible, the stucco is spread upon it to the extent of four or five feet square, and, moistening it continually with a brush as he proceeds, the workman trowels its surface with the float, alternately sprinkling and rubbing the face of the stucco, till the whole is reduced to a fine even surface. Thus, by small portions at a

time, he proceeds till the whole is completed. The water applied to it has the effect of hardening the face of the stucco, which, when finished, becomes as smooth as glass.

2245. From what has been said, the reader will perceive that mere laying or plastering on laths, or rendering on walls, is the most common kind of work, and consists of one coat only; that adding to this a setting coat, it is brought to a better surface, and is two-coat work; and that three-coat work undergoes the intermediate process of floating, between the rendering or pricking up and the setting.

2246. Ceilings are set in two different ways; that is the best wherein the setting coat is composed of plaster and putty, commonly called guage. Common ceilings are formed with plaster without hair, as in the finishing coat for walls set for paper.

2247. *Pugging* is plaster laid on boards, fitted in between the joists of a floor, to prevent the passage of sound between two stories, and is executed with coarse stuff.

2248. The following materials are required for 100 yards of render set; viz.  $1\frac{1}{2}$  hundred of lime, 1 double load of river sand, and 4 bushels of hair; for the labour, 1 plasterer 3 days, 1 labourer 3 days, 1 boy 3 days; and upon this, 20 per cent. profit is usually allowed. For 130 yards of lath plaster and set—1 load of laths, 10,000 nails,  $2\frac{1}{2}$  hundred of lime,  $1\frac{1}{2}$  double load of river sand, 7 bushels of hair; for the labour, 1 plasterer 6 days, 1 labourer 6 days, 1 boy 6 days; and upon this, as before, 20 per cent. is usually allowed.

2249. In the country, for the exterior coating of dwellings and out-buildings, a species of plastering is used called *roughcast*. It is cheaper than stucco or Parker's cement, and therefore suitable to such purposes. In the process of executing it, the wall is first pricked up with a coat of lime and hair, on which, when tolerably well set, a second coat is laid on of the same materials as the first, but as smooth as possible. As fast as the workman finishes this surface, another follows him with a pailful of the roughcast, with which he bespatters the new plastering, so that the whole dries together. The roughcast is a composition of small gravel, finely washed, to free it from all earthy particles, and mixed with pure lime and water in a state of semi-fluid consistency. It is thrown from the pail upon the wall, with a wooden float, about 5 or 6 inches long, and as many wide, formed of half-inch deal, and fitted with a round deal handle. With this tool, while the plasterer throws on the roughcast with his right hand, in his left he holds a common whitewasher's brush dipped in the roughcast, with which he brushes and colours the mortar and the roughcast already spread, to give them, when finished, an uniform colour and appearance.

2250. In the forming the coves and cornices which are applied below the ceilings of rooms, it is of the greatest importance to make them as light as possible, for the plaster whereof they are formed is heavy, and ought not to be trusted merely to its adhesion to the vertical and horizontal surfaces to which it is attached. Hence, when cornices run of large dimension, bracketing, as has already been described in the section Joinery (2079, *et seq.*), must be provided, of the general form of the cornice or cove, or other work, and on this the plastering is to be formed. On this, when roughed out, the work is run with wooden moulds, having brass or copper edges, so as to give the general outline of the cornice. If enrichments are used in it, they are cast in plaster of Paris, and afterwards fixed with that material in the spaces left for them to occupy. These enrichments are previously modelled, and from the model a matrix is formed, as for all other plaster casting. Great nicety is required in all the operations relative to the moulding and fixing of cornices, and most especially that the ornaments be firmly fixed, that they may not be detached from their places by partial settlements of the building, and cause accidents to the occupiers of the rooms where they are used.

2251. In the present time, the use of ornaments made of carton-pierre, a species of papier maché has been reintroduced for cornices, flowers, and other decorations. The basis of it is paper reduced to a pulp, which having other ingredients mixed with it is pressed into moulds, and thus ornaments are formed of it. Though they have not all the delicacy of the plaster cast, their lightness, and the security with which they can be fixed with screws is such, that we have no hesitation in recommending them for adoption, in preference to plaster ornaments; and, indeed, their general use at present warrants the recommendation we here give. At the same time, we must caution the architect that the thing is at present far from the perfection to which the plasterer carries his practice, and that in the fixing there is all the want of that nicety which a good cornice workman in plaster exhibits. There has been a great want of competition in this country of the manufacture of carton-pierre. Indeed of what is made here the modelling is generally very bad, inferior artists being employed upon it. That manufactured by Waillet and Huber of Paris we have found to be the best, and their modellers are able artists. We have already adverted to the cements used in plastering. Parker's, Bailey's, Atkinson's, and Chambers's are the principal ones for coating buildings, and the process of laying them on is so similar to that of other plasterer's work, that it will not be necessary to say more than that they are all good, and may be used with safety.

2252. It is scarcely within the branch of the plasterer's practice, but as we shall have no other place for advertising to it, we may as well here mention a composition which, till lately, was much in use, but will certainly now be entirely superseded by the carton-pierre, above mentioned; we mean what are called composition ornaments, which were never, however, used in cornices, but principally for the decoration of an inferior class of chimney-pieces, and the like. The composition is very strong when dry, of a brownish colour, consisting of about two pounds of powdered whiting, a pound of glue in solution, and half a pound of linseed oil mixed together in a copper, heated and stirred with a spatula till the whole is incorporated. After heating it is laid upon a stone covered with powdered whiting, and beaten to a tough and firm consistence, when it is laid by for use, covered with wet cloths to keep it fresh. This composition is then put into a press, and pressed into moulds made of boxwood. It is now, however, nearly abandoned, as it ought to be, its weight being so much against its use.

## SECT. X.

### SMITHERY AND IRONMONGERY.

2253. Smithery is the art of uniting several lumps of iron into one lump or mass, and forming them into any desired shape. The operations necessary for this are primarily performed in the forge, and on the anvil with the hammer; but for finishing, many other implements and tools are necessary. These, however, we do not think useful to particularise, a course we have pursued in the other trades, because the expedients introduced by the engineer and machinist have of late years, except in rough work, superseded many of them. It is now, for instance, easier to plane iron to a perfect surface than it was a few years ago to file or hammer to what was then always an imperfect one. Formerly a man would be occupied as many minutes in drilling a hole as by machines it now takes seconds to perform.

2254. We have, in a previous section, given all the particulars relating to the produce of the metal from the ore; in this section we propose little more than to enumerate the different objects which the smith and ironmonger furnish in the construction of buildings; and introductory to that it will be convenient to subjoin tables of the weights of round and bar iron, and also of the weights of 1 foot of close hammered bar iron of different thicknesses; remembering that a cube foot of close hammered iron weighs about 495 lbs., of common wrought iron about 480 lbs., and of cast iron 450 lbs., whence may be derived the weight of other solids whose cubic contents are known.

If of Cast Iron.								
12	4·835	9·664	14·500	19·336	24·172	29·000	33·836	38·672

2255. For the carcass of a building the chief articles furnished by the smith are *chimney bars*, which are wide thin bent bars or plates of iron, to relieve the weight of brickwork over wide openings of chimneys, as in kitchens and rooms where a large area of fire is requisite. In these situations they are subject however to objection, because of their liability to constant expansion and contraction from the varying temperature, which often produces fractures about the chimney jambs. They nevertheless, on the whole, produce a security which sanctions their use. *Cramps* for holding together courses of stonework. These, however, are better of cast iron, being far less subject to decay by oxidation. *Balusters and railing* for stairs and the areas of houses towards a public way. *Shoes for piles*, when that mode of obtaining a foundation is adopted. *Wrought iron columns with caps and bases*, for the support of great superincumbent weights. Cast iron are now preferred both for economy and stiffness; as is also that material for girders and bressumers, which have been already disposed of in a previous page. *Area gratings and window bars* for securing the lower stories of houses. Here, again, the founder has stepped in to render the employment of wrought iron much less general than formerly. *Ties* of all descriptions, and for the carpenter especially the various sorts of *straps, bolts, nuts and screws, plates, washers*, and the like, for connecting the pieces in framing where the strain is greater than the mere fibres of the wood will resist. *Casements*, with their fastenings for lead lights, are also furnished by the smith. But he is now rarely employed, as heretofore, for fancy gates, sashes, and frames, such works being furnished by the founder, as well as rain-water pipes with their cistern heads, pavement gutters, air traps, scrapers, coalplates, water-closet traps, and a number of other objects which will occur to the reader.

2256. The chief articles furnished by the ironmonger are for the joiner's use, and, except in particular cases, are kept in store by that tradesman for immediate supply as required.

2257. They consist in *screws*, whose common sizes are from three quarters of an inch up to 4 inches in length. They are sold by the dozen.

2258. *Iron butt hinges*, whose name is probably derived from their butting close surface to surface when closed, used for hanging doors and shutters. They are made both of iron and brass, the former varying in size from  $1\frac{1}{4}$  to 4 inches in length; the latter from 1 inch to 4 inches. These, as well as all other hinges, are in size necessarily proportioned to the magnitude and consequent weight of the shutters or doors they are to carry; and it is to be observed, that for the well-hanging of a door or shutter, the size of the hinge should be rather on the outside of enough than under the mark. There is a species of hinge used for doors called the *rising joint hinge*, a contrivance in which the pivot, having on it a short portion of a spiral thread, and the part to which the door is fixed having a correspondent mass, the door in opening rises, and clears the carpet or other impediment usually placed on the floor. The *projecting brass butt* is used when the shutter or door is required to clear some projection, and thus, when opened, to lie completely back in a plane parallel to its direction when shut. All hinges are purchased from the ironmonger by the pair.

Besides the hinges above mentioned are those called *cross garnets*, whose form is , that of a **T** lying sidewise. These are only used on the commonest external doors, and are made from 10 to 20 inches, varying in their dimensions by differences of two inches. **H** hinges, the shape of the letter **H**, showing their form as well as the origin of their name. These in their sizes range from 3 to 8 inches by differences of an inch. **HL** hinges (**H** and **L** conjoined), whose form is implied by their name, and whose sizes are from 6 to 12 inches, proceeding by inches. *Parliament hinges* are made of cast and wrought iron, from  $3\frac{3}{4}$  to 5 inches, proceeding in size by half inches.

2259. *Rough rod bolts* are those in which there is no continued barrel for the bolt, and are for the most common service. Their sizes begin with a length of three inches, and proceed by inches up to a length of 10 inches; such, at least, are their common sizes. *Bright rod bolts* run of the same sizes as the last; and, as the name indicates, the bolt is polished and finished, so as to make them a better fastening, as far as appearance is concerned. The *spring plate bolt* is contrived with a spring to keep the bolt up to its work, but one which so soon gets out of order that we wonder it is now manufactured or used. It is made of lengths from 3 to 8 inches, by variations of an inch in size. *Barrelled bolts* are those, in which the whole length of the bolt is enclosed in a continued cylindrical barrel, and are superior to all others in use, as well as the most finished in their appearance. Their common sizes are from 6 to 12 inches, varying by steps of an inch. All the bolts above mentioned are sold per piece by the ironmonger, as are those called *flush bolts*, a name given to such as are let into the surface to which they are applied, so as to stand flush with it. They are mostly made of brass, and are of two different thicknesses, viz. half and three quarter inch. Their lengths vary from  $2\frac{1}{2}$  to 12 inches, and occasionally, as circumstances may require, as in book-case doors and French sashes, to a greater length. But for French casements, what is called the *Espaniolette bolt*, a contrivance whose origin is French, though much improved in its manufacture here, is now more generally in use.

2260. *Pullies*, for hanging sashes and shutters, are made of iron or brass, or with brass sheaves or brass axles. Their sizes are from one inch and a half to two inches and a half in diameter.

2261. The varieties of locks, their contrivances for security, and their construction, are so many, that to describe them minutely would require almost a work of itself. All that the architect has to deal with, for common purposes in building, we shall mention. For fastening places where particular security is requisite, as strong closets for plate or cash, some of the patented locks should be used, and we must leave this matter for inquiry in the hands of the architect. Every patentee says his invention is the best. We nevertheless believe, notwithstanding the boasts of all the inventors, no lock has yet appeared which an expert locksmith acquainted with its construction will not be able to pick. The locks in common use are *stock locks*, whose box is usually of wood, and whose sizes vary from 7 to 10 inches. *Dead locks*, whose sizes are from 4 to 7 inches, and so called from the key shooting the bolt home dead, without a spring. *Cupboard locks* of 3,  $3\frac{1}{2}$ , and 4 inches in size. *Iron rim locks*, whose box or case is made of iron, and which are fitted on to one of the sides of a door, and whose sizes are from 6 to 8 inches. Of those made of the last-named size, there are some, as also of 9 inches, which are used for external doors, called *iron rim drawback locks*. For the doors of all well-finished apartments, *mortice locks* are used. These take their name from being morticed into the thickness of the door, and being thus hidden. To these either plain or fancy *furniture*, that is, knobs and escabecons, are affixed. Above and below them *finger plates* are generally directed to be placed, to prevent the door being soiled in the places where it is mostly laid hold of.

2262. The different sorts of latches in use are the *thumb latch*, which receives its name

from the thumb being placed on the lever to raise its latch; the *Norfolk latch*; the four-inch *bow latch* with brass nobs; the brass *pulpit latch*; and the *mortice latch*.

2263. Besides the articles already mentioned, *spikes, holdfasts, and wall hooks, door springs* of various sorts, *door chains and barrels, thumb screws* and other shutter and sash fastenings, *brass turn buckles, closet knobs, brass flush rings, shutter bars, brass rollers, bars with latches, shelf brackets, drawer handles, wrought iron bars, sash lines and weights*, besides many others, are furnished by the ironmonger. In treating on specifications, in a subsequent section, it will be seen how the several articles of smithery and ironmongery are applied.

2264. Bolts, straps, and other exposed iron-work are preserved from the action of moisture on them by the following mixture:—To two quarts of boiling oil add half a pound of litharge, putting in small quantities at a time, and cautiously. Let it simmer over the fire two or three hours; then strain it, and add a quarter of a pound of finely-pounded resin and a pound of white lead, keeping it at a gentle heat till the whole is well incorporated. It is to be used hot. A composition of oil and resin and finely levigated brickdust is found useful in preserving iron from rust. It is to be mixed, and used as a paint of the usual consistence.

## SECT. XI.

### FOUNDERY.

2265. The very general use of cast iron by the architect has induced us to give, in a previous section, a succinct account of the common operations of foundry, or the art of casting metal into different forms. We do not think it necessary, therefore, to do more than refer the reader to Chap. II. Sect V. of this Book (1763. *et seq.*). The foundry of statues, which is among the most difficult of its branches, belongs exclusively to the sculptor, and is usually carried on in bronze.

2266. To gain a proper knowledge of the operations of the founder, the student should attend a few castings at the foundry itself, which will be more useful to him than all which in words we can express on the subject.

## SECT. XII.

### PAINTING, GILDING, AND PAPER-HANGING, ETC.

2267. Painting is the art of covering the surfaces of wood, iron, and other materials with a mucilaginous substance, which, acquiring hardness by exposure to the air, protects the material to which it is applied from the effects of the weather.

2268. The requisite tools of the painter are—*brushes of hog's bristles*, of various sizes suitable to the work; a *scraping or pallet knife*; *earthen pots* to hold the colours; a *tin can* for turpentine; a *grinding stone and muller*, &c. The stone should be hard and close-grained, about 18 inches in diameter, and of sufficient weight to keep it steady. The knots, especially of fir, in painting new work, will destroy its good effect if they be not first properly *killed*, as the painters term it. The best way of effecting this is by laying upon those knots which retain any turpentine a considerable substance of lime immediately after it is slaked. This is done with a stopping knife, and the process dries and burns out the turpentine which the knots contain. When the lime has remained on about four and twenty hours, it is to be scraped off, and the knots must be painted over with what is called *size knotting*, a composition of red and white lead ground very fine with water on a stone, and mixed with strong double glue size, and used warm. If doubts exist of their still remaining unkilld, they may be then painted over with red and white lead ground very fine in linseed oil, and mixed with a portion of that oil, taking care to rub them down with sand paper each time after covering them when dry; so that they may not appear more raised than the other parts. When the knotting is completed, the *priming colour* is laid on. The priming colour is composed of white and a little red lead mixed thin with linseed oil. One pound of it will cover from 18 to 20 yards. When the primer is quite dry, if the work is intended to be finished white, mix white lead and a very small portion of red with linseed oil, adding a little quantity of spirits of turpentine for second colouring the work. Of this second primer, one pound will cover about 10 to 12 square yards. The work should now remain for some days to harden; and before laying on the third coat, it should be rubbed down with fine sand paper, and stopped with oil putty wherever it may be necessary. If the knots still show through, they should be covered with silver leaf laid on with jappaned gold size. The third coat is white lead mixed with linseed oil and turpentine in equal portions, and a pound will cover about 8 square yards. If the work is not to be finished

white, the other requisite colour will of course be mixed with the white lead, as in the case of four coats being used. When the work is to be finished with four coats, the finishing coat should be of good old white lead as the basis, thinned with bleached linseed oil and spirits of turpentine; one of oil to two of turpentine. If the work is to be finished *dead white*, the very best old lead must be used, and thinned entirely with spirits of turpentine.

2269. When stucco is to be painted, it will require one more coat than wood-work; the last coat being mixed, if the work is as usually executed, with half spirits of turpentine and half oil, for the reception of the finishing coat of all turpentine or flattening. If the work be not flattened, the finishing coat should be with one part oil and two of turpentine. It would be impossible to enter into the details which are to be observed in painting walls of fancy colours; all that can be said on this point in instruction to the architect is, that when fancy colours, as they are called, which in these days a painter construes as anything but white and a tinge of ochre or umber, each coat must incline, as it is laid on, more and more to the colour which the work is intended to bear when finished.

2270. In repainting old work, it should be well rubbed down with dry pumice stone, and then carefully dusted off, and when requisite, the cracks and openings must be well stopped with oil putty. After this, a mixture of white, with a very small portion of red lead, with equal parts of oil and turpentine, is used to paint the work, which the painters technically call second colouring old work. After this, the work being dry, a mixture of old white lead, adding a small portion of blue black in a medium of half bleached oil and half turpentine, is used for finishing, or, if flattening be intended, the former preparation will be suitable for receiving dead white or any fancy colour. The same process will serve for stuccoed walls, observing that, if more coats be required, the mixture of half oil and half turpentine is proper.

2271. In respect to outside work, the use of turpentine is to be avoided, for turpentine is more susceptible of water than oil, and thence not so well calculated to preserve work exposed to the weather. Oil, however, having from its nature a natural tendency to discolour white, that is necessarily finished with a portion of half oil and half turpentine; but in dark colours this is not necessary, and in such cases, boiled oil, with a little turpentine, is the best, or indeed boiled oil only.

2272. White lead, which is the principal basis of all stone colours, is carbonate of lead. It is usually made either by precipitation, as when carbonic acid or a carbonate is used to decompose a soluble salt, or a subsalt of lead; or by exposing plates of cast lead to the joint action of the vapour of acetic acid and carbonic acid. It is by the latter process only that the resulting carbonate of lead is obtained of that degree of density, opacity, and perfect freedom from crystalline texture, which fits it for paint. The last, called the Dutch process, was introduced into England about 1780. White lead is often largely adulterated with sulphate of baryta, which may be detected by insolubility in dilute nitric acid, whereas pure white lead is entirely dissolved by it. The ill effects on the constitution of parties engaged both in the manufacture and use of the article, have recently (since the publication of the first edition of this work) induced the French chemists to find some less deleterious substitute for it, and M. de Ruolz has discovered two substances which fulfil the required conditions—viz., combination with oil, good colour, property of concealing, &c. The first is an arsenical compound (product) hitherto little known, which M. de Ruolz does not describe, because, although inoffensive it may be made, by very simple chemical reaction, to retake its poisonous qualities, and be employed criminally. The second, which he considers well adapted for use, is the oxide of antimony, which is a very pure white, rivaling the finest silver white, and is very easily dried, and forms a very unctuous and cohesive mixture; comparatively with the white lead, or the oil, as to the latter, it gives much clearer and softer tones than white lead. It may be obtained directly from the natural sulphuret of antimony, and at one third of the cost of ordinary white paint. (See "Literary Gazette," 25. Nov. 1843.) If the finishing colour is white, nothing but white lead should be employed. Lead colours are formed by a mixture of white lead with lamp black; all colours, however, that are called *fancy colours*, have white lead for their basis, chocoates, black, brown, and wainscot only excepted.

2273. There is a process used by painters, termed *clear-coaling*, which is executed with white lead ground in water, and mixed with size. This is used instead of a coat of paint; but it has not sufficient body, and is to answer the end for which it is usually employed. It scales off, and in immediately changes. The only occasions wherein it is useful, are where the use of it prepares better for the reception of paint. It should, however, never be employed upon joiner's work or cornices to ceilings, where much enrichment is found; for of all things, it destroys the sharpness and beauty of the ornaments. Painters are very fond of using it; but their endeavours to persuade the architect should always be resisted, except in cases of absolute necessity, namely, that in which a fair appearance of black especially, and in damp weather parts of copperas and litharge, ground

1 lb. of red lead, 1 lb. of umber, and 1 lb. of oil, must be taken that the oil does not be thereby exposed. Thus, in a pot than one-third of that quantity.

together.

2276. The extra or fancy colours used in painting are drabs, French greys, peach blossom, lilac, light greens, patent greens, blues, vermilion, lake, &c. All imitations, too, of woods and marbles, are executed by the painter, and these are always covered with one or more coats of varnish.

2277. In outside work and stairs, the process of *sanding* is frequently adopted. It is performed with fine sand thrown on the last coat of paint while wet. The method of gilding is also frequently adopted. The gold leaf used is of the finest quality, and is furnished by the goldbeater in books of 25 leaves, each leaf being  $3\frac{1}{2}$  by 3 inches, or in the book, 1 ft. 6 in. and  $\frac{1}{8}$  of an inch superficial.

2278. With painting is often connected the practice of paper-hanging by the same artificer. The various sorts of paper used for lining walls it would be useless to describe. We have only to mention that papers are printed in pieces of 12 yards in length, and 1 foot 8 inches wide; hence, 1 yard in length contains 5 feet superficial; therefore, any

number of superficial feet divided by 60 (the length  $36 \times 1$  ft. 8 ins.) will give the number of pieces wanted for the work. A ream of printed paper of 20 quires of 24 sheets to the quire is equal to 28 pieces of paper, or each piece contains 17 sheets.

### SECT. XIII.

#### SPECIFICATIONS.

2279. The importance of an accurate specification or description of the materials and work to be used and performed in the execution of a building, is almost as great as the preparation of the designs for it. The frequent cost of works above the estimated sum, and its freedom from extra charges on winding up the accounts, will mainly depend on the clearness, fulness, and accuracy of the specifications; though it is but justice to the architect to state that extras arise almost as often from the caprice of his employer during the progress of the work, as from the neglect or carelessness of the architect in making the specification. A specification should be made in all cases of new designs, additions, or alterations in reference to designs, which, the more they are given in working drawings by the architect, the better will it be for his employer, no less than for the artificer.

2280. It is impossible to frame a set of directions which shall be applicable in all cases. What we here propose to do is, to give something like a list or skeleton of the component parts of buildings, from which the architect may select such as are suitable to the particular case whereon he may be engaged. We have not carried this into the repairs and alterations of houses, because, with difference of application, we apprehend what we are placing before the student will enable him to carry the system forward in such cases without any difficulty. The works of each artificer are as follow:—

2281. **EXCAVATOR.** To take down any old buildings and impediments that may be on the site of the new works. If any old materials are to be used again, he is to clean, sort, and stack them for re-using in such parts of the premises as may be directed. The rubbish, as well from these as from any superfluous earth that may come out of the basement and foundations, if not wanted for raising the ground or for other purposes, he is to cart away, either wholly, or to such part of the premises as may require it, on direction to that effect, as well as all rubbish that may accumulate in executing the works.

To dig out for basement story (where one is to be) for the foundations, areas, drains, floors, and all other works requisite. To beat down to a solid consistence the ground forming the beds of the trenches for receiving the foundations and walls, and after they are in, he is to fill in and ram down the ground with wooden rammers; to level, and to do such other rough groundwork as may be necessary for forming the sectional ground lines shown upon the drawings. In basements no earth is to be left nearer than 9 inches to any floor or other timbers, such cavities being by the specification to be filled in with dry lime core. And, finally, he is to leave the ground altogether free from all useless soil or other materials.

To hale out or pump out and remove all soil and water which may be necessary for laying the foundations, whether arising from springs, drains, cesspools, rain, or otherwise, and to be answerable for all accidental damage that may occur whilst the foundations and walls are carrying up, as also, when buildings adjoin, for all damage that may occur to neighbouring buildings.

2282. **BRICKLAYER.** The brickwork is to be executed with the very best hard well-burnt grey stocks (or kiln-burnt red stock bricks, if the others are not to be had), to be laid in flat joints, and so that every four courses shall not exceed  $11\frac{1}{2}$  inches in height.

When better bricks are used for facing external walls, they are to be specified as *best marle stocks*, *second marle stocks*, or *Suffolk white bricks*, as the case may be, in which case it must be specified that no headers of the facing arc to be cut off, except where absolutely necessary to form good bond. Fronts so faced must be described to be either carried up with a neat flat parallel ruled joint, or to be afterwards tuck-joint pointed if a very finished face is wanted, though the latter is not altogether a very sound practice. In old work the joints may be described to be raked out, the brickwork washed, stained, and tuck-joint pointed.

No *place* or *samile* bricks to be allowed in any part of the work, under a penalty of two shillings for every such brick that may be detected to have been used.

The mortar is to be compounded of stone lime and sharp clean drift sand (if the work be of importance), to be ground in a pug-mill, or otherwise to be well tempered and beaten with wooden beaters, and to be in the proportion of one heaped bushel of lime to two of sand.

**BRICKLAYER.**

When the foundations are bad, *concrete* should be provided, and is thus described: it is to be formed in the proportion of six parts of Thames or other unscreened clean ballast, and one part of fresh-burnt Dorking (or other) *stone* lime, beaten to powder on the premises, and unslaked. They are to be thoroughly mixed in small quantities at a time, the lime at mixing being slaked with as small a quantity of water as possible. The concrete, after mixing, is to be dropped from a stage to be formed by the contractor, so as to fall into the trench provided for its reception from a height of at least 12 feet. The thickness of the concrete thus executed may vary from 4 feet to 18 inches in height, according to the badness or goodness of the foundation.

*English bond* should be directed, and the work should be specified to be flushed up at every course with mortar. No bats to be allowed except for closures; and for sound work every fourth course to be *grouted* with liquid mortar, and in the foundations every course, or at least every second course. The walls, chimneys, their shafts and other works are to be carried up of the height and thicknesses and in the manner shown and figured on the several plans and drawings, together with all brickwork requisite for the completion of the house. If the architect prefers, he may particularise these, but the drawings will show his meaning better. When the work is within the bills of mortality, and not required to be of particularly great solidity, it will be sufficient to describe that the thicknesses of the walls, their heights above the roofs, &c., shall be conformable to the regulations contained in the Building Act of the 14th Geo. III. c. 78.

When the work is to appear without a stone or plaster facing, there must be described *rubbed* and *gaged arches* for all the external openings that will be seen in the principal fronts, of 9 or 14 inches in depth (or more according to their span), accurately cut, and set closely in front, in back, and on their soffits. To the other openings the arches are to be described plain arches, closely set; those which appear externally to be tuck-pointed on their outside faces. Over all lintels, too, in external walls, the specification should provide uncut accurately formed arches.

When *fascias* are formed of brick, they must be described with their projections, as also all cornices formed by the arrangements of bricks, whereof the heads may be required to show as modillions; but a drawing should, for the latter, always appear on the drawing or specification.

When the shafts of chimneys are carried up above the roof, out of the common way, they must be referred to drawings; otherwise what relates to them and their flues is merely described as follows:—*Turn, parget, and core* the chimney flues, and finish the shafts with salient courses 6 inches in height, with *double plintile creesing* thereto, and for each flue provide and fix a large-sized chimney mould; the upper courses of the shafts above the creesing to be laid in Parker's cement. In most cases, now, the flues are covered with square chimney moulds, cast of Parker's cement, and may be described as plain or moulded, and otherwise ornamented.

When parapets are not to be coped with stone or cement, they must be described as finished with double plintile creesing, and a brick on edge thereover, all laid in Parker's cement.

Generally, where weather is to be provided against in upper courses and elsewhere, the laying in Parker's cement must be described.

Turn *trimmers* of 4-inch brickwork to all the fire-places for receiving the hearths throughout the building, except where the hearths lie on ground in basement stories.

Where there are basement stories, or the story is on the ground. Describe piers 9 inches square, or continued walls 9 inches thick, to carry the sleepers whereon the joists of the floor or the courses of paving stone are to lie; in either case the cavity is to be filled, for at least 9 inches in height, with dry lime core.

Bed in mortar all bond timber, wall or other plates, lintels, wood, bricks, templets, stone, or other work connected with the brickwork. All the door and window frames to be bedded in and pointed round with lime and hair mortar. Execute all requisite beam fitting.

When the building is faced with stone, or stone dressings are used; to the above must be added—back up and fill in solid with brickwork all the stone work and iron work that is set in the brickwork.

If cornices, fascias, &c. are to be run in Parker's cement, or other sort of plaster, the instruction is—Prepare and fix brickwork, and such Yorkshire stone slabs and other materials as may be necessary for forming the several external cornices, pediments, strings, sills, and dressings to openings, in Parker's cement, or other cement, as the case may be, as shown on the drawings.

Turn arches in cement (if wanted) for carrying entrance or other steps. Provide all brickwork for stone steps. Turn vaults of brickwork (describe thickness not less

**BRICKLAYER.**

than 9 inches) over the intended cellars, according to the drawing, and properly cut all groins of intersections. The spandrels to be filled in with solid brickwork up to the level of the internal crown of the vaulting, the whole grouted with liquid mortar. When the centering is struck, the soffits of the vaultings are to be evenly and fairly cleaned off, and pointed.

Construct round the building a dry drain, as shown on the drawings, the top of the wall thereof to be level with the sections of the ground. Ram down the ground at the back thereof as the work is carried up, and provide such stone stays from the building as may be necessary for maintaining such wall in its place.

To execute proper barrel drains for draining the premises, as shown on the plans, to fall into a main sewer, or cesspool, as the case may be. The principal drains to be 1 ft. 6 in. and the smaller ones 12 inch barrelled drains, with half-brick rims, and the lower half of each drain composed with pure Parker's cement. At the foot of all rain-water, soil, and waste pipes, proper brick funnels are to be formed to lead down to the drain, the same to be constructed in Parker's cement. From all sink-stones funnels and drains to be formed to lead to the principal drains. N.B. We have here described the sizes of drains as for a moderate-sized mansion. We might say that 30 inches is the maximum diameter likely to be required for a large building, and none should be made less than 9 inches wide with half-brick sides, three courses high, arched, and paved.

When a portico is designed, provide and execute walls for carrying the columns of portico, as shown on the plan, all piers or cross walls for receiving the landings, and brickwork to receive the steps. If the portico be of large size, describe discharging arches above the architrave in the space over intercolumniations, and from return columns to main walls. If a pediment, back up with brickwork behind the tympanum of pediment quite up to under side of raking cornice of pediment.

Wells, when above 6 feet in diameter, should be described to be steamed in a thickness of one brick, and when less than that size, in half a brick.

When water cannot be carried off to a public sewer or running stream, *cesspools* must be formed to receive it, and allow, if possible, its absorption by the earth. They are usually 3 feet 6 inches to 5 feet clear diameter, and are to be described as circular on plan, steamed round with hard stocks, in half a brick thick, laid dry till within 18 inches of the top, which 18 inches are to be laid in Parker's cement. If there be privies or water-closets far apart, each must be provided with a cesspool. Cesspools are sometimes domed over in brickwork, with a circular stone let into the eye or opening at the top of the dome; or they may be described to be covered with Yorkshire stone.

If any fence walls are required, their footings, thicknesses, heights, and lengths are to be mentioned, and of what bricks they are to be built. If any thing peculiar in their form, a section and elevation should be given.

*Bricknogged partitions*, which in practice ought, if possible, to be avoided, and are only to be justified where room is an object, are described as with bricks laid flat, or on edge, filled in between the quarters, ties, &c. of the partition.

*Strong closets* for plate or deeds require merely description of thickness of walls and brick arch, and usually 4-inch walls brought up for holding the requisite number of shelves. The same of wine cellars, whose bin walls must be mentioned.

*Paving with bricks* is described to be either of stocks, paving bricks, malm paviers, or clinkers, which may be laid flat or on edge in sand, mortar, or cement, and either straight-coursed or herring-bone.

*Paving with tiles* is usually in mortar; the tiles may be either 10 or 12 inches square. *All plays, ramps, and chases* to be cut where wanted; the two former to be rubbed where necessary, and the latter to be pargetted.

*Brick ovens* (one 10 feet wide and 8 feet 6 inches deep will bake twelve bushels of bread, and one 8 feet wide and 7 feet deep will bake eight bushels, and so in proportion) are to be constructed with Welsh lumps or fire bricks for fire-place, domed over, and hooped with iron hoops. The bricklayer is to provide the bars, plate door, bar to the archway of door, and other ironwork, and to carry up a proper flue from the fire.

*Iron ovens.* The bricklayer is to set in proper brickwork an iron oven capable of baking two bushels of bread.

*Coppers and stewing stoves* to be set neatly in brickwork, the latter in gauged brickwork with tile top, and proper flues carried up therefrom.

*Columns* to porticoes or fronts which are to be coated with cement must be described of such diameters as the drawings for finishing require, with entablature, &c., as the case may be, carried up in Parker's cement.

In describing stables, besides what may be applicable from the foregoing directions, two *air-flues* are to be constructed to each stall and loose box, 9 inches square, and

**BRICKLAYER.**

carried up over the racks within the thickness of the brickwork, communicating at their tops with the external air by curved tops to secure them from the penetration of the rain. *Dung-pit walls*, whose dimensions depend on the size of the stables.

*Lime white walls* of stables.

If roofs are covered with tiles, either pan or plain. The description for the former will be either laid dry, or bedded in lime and hair, or pointed outside or inside, or on both sides; or if glazed pantiling, to be so described, laid to a 10-inch gauge on stout fir laths, with hip, ridge, and valley tiles, filleting cutting to splays, beam filling, painted T nails, hip hooks, &c. *Plain tiling* is described as laid to a close gauge on heart of oak double laths, with all the plain tiles pegged. The hip and ridge tiles to be set in Parker's cement, with T nails dipped in melted hot pitch in all the joints. Strong, similarly pitched, wrought iron hip hooks. Filletings of Parker's cement, with strong cast iron nails for forming a key driven into the walls or other brickwork at intervals, close enough to secure the same.

In cases of underpinning the bricklayer is to cut all holes for the needles, and to remove the old work, and to bring up the work in Parker's cement on concrete foundation; and, finally, drive the cast iron wedges for bringing the work to a solid bearing.

Where inverted arches are used in foundations they must be shown on the drawings.

Provide, according to the extent of the job, a certain number of rods of brickwork for such extras as may be ordered by the architect; and if the whole or any part thereof should not be wanted, a deduction to be made on settling the accounts for so much thereof as shall not have been used, at a price per rod to be named.

To build all the walls level, except otherwise directed; to be answerable for all damage that may occur to the work, by settlements or otherwise, during the time of building, and to make good the same as the architect shall direct; and, further, to perform all such jobbing work as shall be necessary for completely finishing the building. To provide good sound and sufficient scaffolding, which is to remain for the use of the mason, carpenter, and other artificers that may have occasion to use the same.

To pay the proper fees to the district, sewer, and paving surveyors, and to give the necessary notices and obtain the proper licences in their departments for executing the works. This only applies in the bills of mortality, where there are such officers.

2283. **SLATER.** To cover the roofs with the best strong Westmoreland, Tavistock, Welsh rag, imperial, queen, duchess, countess, ladies, or double slating, (as the architect may think most appropriate, each being named in the order of the value and quality,) securely fixed with best strong copper nails. Every part to be properly bonded, especially at the eaves and heading courses thereof, with slates cut to keep the bond uniform. No slates to be laid lengthwise.

Fillets against the brickwork, where requisite, of Parker's cement; such fillets to be formed with nails driven at proper intervals to form a hold for the cement (where lead step flashings are intended the fillets need not be described). Fillets of brick or stone may be built up with the wall, level or raking; and if they should be preferred by the architect, they must be described in the bricklayer's or mason's works.

All the slating is to be rendered up perfect on completing the building, and all jobbing work to be performed that may become necessary as the work is carried on.

If the slating is required to be rendered as air-tight as possible, it must be described to be pointed on the inside with stone lime mortar, with a proper quantity of hair therein; but the pointing of either slates or tiles, from the constant expansion and contraction arising from heat and cold, soon falls out and becomes useless. Slater to be answerable twelve months for his work.

If slate skirtings and cisterns are intended about the building, they must be particularly described.

2284. **MASON.** The stone to be used in a building generally depends of course on the place where it is to be built, unless, without regard to expense, the employer determines on the use of any particular sort; in which case the account of the different quarries of the provinces, given in Chap. II. Section II. of this Book, will furnish the architect with the means of describing the best of its sort. For the choice, therefore, where it is left to the architect to decide, we must refer him to that account. In the neighbourhood of London that from the island of Portland is most used. Granite is chiefly used where great strains and pressures occur, or where wear and tear and the action of the weather indicate its employment.

Having described the sort of stone selected to be of the best quality, free from all vents, shakes, &c., the next direction is, that it shall be throughout laid in the direc-

**MASON.**

tion of its natural bed in the quarry; and if the whole building is of stone, many of the following particulars will be unnecessary,—which of them will immediately speak for themselves. Where the building is only faced with stone, the specification will run as follows:—The . . . fronts (describing them) are to be faced with Portland (or other, as the case may be) stone, ashlar in courses to fall in with the courses of brickwork, carried up after the manner of Flemish bond. The stretchers of such ashlar being  $4\frac{1}{2}$  inches deep and the headers 9 inches, with bond stones running through the whole thickness of the wall in the proportion of  $\frac{1}{16}$  of the face, to be introduced where the piers allow. No quoins to show a thickness of less than 12 inches. The whole to be cramped with iron cramps to the satisfaction of the architect, the mason finding the same, and properly running them with lead.

In cases where the building is of brick with stone dressings, the specification will run thus:—To provide and set a Portland stone (or other stone or granite) plinth all round (or part, as the case may be) the building, . . . feet . . . inches high and  $8\frac{1}{2}$  thick, in stones not less than 3 feet in length, the vertical joints to be cramped with T cramps not less than 12 inches long. Describe whether joints are to be close or channelled, and whether ashlar is to be rusticked (rockworked). To provide and fix at the angles of the building, as shown upon the drawings, solid quoins of Portland (or other, as the case may be) stone [here describe whether close, chamfered, or channelled joints, and whether rusticked (rockworked)] of the length and height shown.

To provide and fix, as shown, string courses, scantling . . . inches by . . . inches, throated and bevelled on the upper face, and the joints plugged with lead.

To provide and fix, as shown on the drawings, a cornice and blocking course, scantling . . . by . . . , moulded according to the drawings, the bed to be such that the weight of each block of stone in the projecting part shall not be equal to that on the bed by one fourth of its cubic contents. The same to be executed according to the drawings; to have proper sunk water joints, and to be channelled and plugged with lead at all the joints.

Blocking course, as shown on the drawings, . . . inches high, . . . thick on the bed, and . . . on the top, plugged with lead at all the joints, with solid block at the quoins returned at least 24 inches.

Balustrades (if any) to be provided of the heights and sizes shown on the drawings and section thereof. The balusters to be wrought out of stone, allowing at least 1 inch of joggle at their ends into the plinth and impost. All the vertical joints to be well plugged with lead; the impost to be cramped with cast iron (or bell metal), and the whole to be securely fixed. The half balusters to be worked out of the same block of stone as their adjoining pedestal.

Columns and pilasters (if any), with pedestals, capitals, bases, plinths, &c., and entablature, to be provided and fixed as shown on the drawings. The columns and pilasters not to be in courses of more than . . . blocks of stone. The architraves to be joggled from those resting on the columns or pilasters themselves, and these as well as the frieze and cornice to break joint over the architrave. The architraves, if blocks of stone can be supplied large enough, to be in one block from centre to centre of column, with return architraves in like manner. The whole of the entablature (as well as the pediment, if any) to be executed with all requisite joggles and cramps; and if a pediment be projected, the apex to be in one stone, as shall be approved by the architect. The pilasters (if any) to be bonded not less than . . . inches into the wall, against which they are placed in every other course. The soffits of the portico to be, as shown on the plan and sections, formed into panels and ornamented. Provide and let into the top of the architrave good and sufficient chain bars, with stubs on the under side for letting into every stone composing the architrave.

If the portico be very large, it is not necessary to make the frieze solid, but concealed arches should be turned in the space from column to column to support the superincumbent weight of the cornice and pediment. If the columns are fluted, it must be mentioned.

When a pediment, the tympanum may be described to be faced with ashlar.

To construct and fix dressings and sills to the external windows and doors, as shown on the drawings, with all such throated, sunk, moulded, carved, rebated, and other works as may be necessary.

If a portico is shown, to provide and fix of solid . . . stone . . . steps round the portico scantling . . . by . . . , properly back-jointed and worked all over; and within the portico to provide and fix a complete landing of stone, at least 4 inches thick (or less, if a small portico), in slabs, as shown. The joints of the steps and landings are to be joggled and run with lead.

**MASON.**

All ornaments, carving, enrichment of capitals, of columns and pilasters, and of such as may be shown in the entablature, is to be executed in an artist-like good style.

Models from the working drawings are to be made at the contractor's expense, and the whole to be executed to the satisfaction of the architect.

The order may be described if the working drawings are not sufficiently made out.

Provide and fix plinths and base mouldings to the portico, as shown on the drawings, to be worked out of (describe stone) . . . stone of . . . by . . . scantling.

Finish the chimney shafts with mouldings as shown in the drawings, or with sunk moulded and throated copings, . . . inches wide and . . . inches thick.

To describe sills generally, take the following : —

Sills to . . . windows of Portland stone, 9½ by 6 inches.

Sills to . . . windows moulded and of Portland stone, 14 by 8 inches.

Sills to . . . windows of Aberdeen granite, finely tooled, scantling 14 inches by 9 inches.

Sills to . . . windows of Portland stone, 9 by 5 inches.

All window sills are to be properly sunk, weathered, and throated, and at each end to be 4 inches longer than the opening.

To provide and lay to all the walls Yorkshire stone 3 inches thick and 4 inches on each side wider than the several lowest footings, in slabs of one length across the width of the footing.

If balconies to a house, describe thus : — A balcony landing of Portland stone . . . inches thick, moulded on the edges and the pieces joggled together, and run with lead, to be provided with holes cut therein for the iron railing. The said balcony is to be tailed into the wall, and securely pinned up.

Steps to doorways must be described as to scantlings. All external steps should be weathered.

Where story posts are used in a front, it is well to place along the front two pieces of parallel square Aberdeen or other good granite curb scantling, 12 inches by 9 inches, cut out to receive the bases of the columns and story posts.

For a back staircase, carry up and construct a staircase from the basement to the principal floor, with solid Yorkshire quarry steps 13 inches wide and 6½ inches high, properly back-jointed and pinned into the brickwork; cut holes for the iron balusters. N. B. This sort of staircase of Portland will serve also for back stairs of upper flights. That from the basement may also be made of granite street curb, 12 by 7 or 8 inches. A staircase may, for cheapness, be made of Yorkshire stone paving 3 inches thick, wrought with fair tooled edges, and securely pinned into the brickwork.

Principal stairs to be of Portland stone (as may be), to extend from principal to . . . floor, with steps and square (or semicircular, as may be) landings, entirely of solid stone, tailed 9 inches into the brickwork, with moulded nosings and returned nosings, and also at the back. The soffites to be moulded to the shapes of the ends of the steps. The landings to be 6 inches thick, with moulded nosings and joggled joints, run with lead, to be inserted at least 4 inches in the walls, but such as tail into the walls, as steps, must go at least 9 inches into the walls.

When the under sides of the steps of the geometrical staircase are not moulded, the nosings are returned so as to fall beyond the upright line of the succeeding tread; in this case the soffit or string is plain wrought.

Pave the entrance hall and principal staircase, together with (any apartments wished) with the best . . . marble, and border according to the pattern drawn.

The back staircase (and such other parts as require it) is to be paved with Portland stone 2 inches thick, laid in squares, and with a border 8 inches square.

Dairy, if any, to be paved with . . . stone, in regular courses . . . inches thick. Provide a shelf or dresser round the said dairy of veined marble 1 inch thick, and a skirting round it 6 inches high. The dresser to go into the wall 1 inch, and to be supported on veined marble piers 4 inches square.

Pave the scullery, larder, pantry, passages, lobbies (and such other places as may require mention), with rubbed Yorkshire stone 2½ inches thick, laid in regular courses with close rubbed joints.

Pave the bottom of the air drain with Yorkshire paving.

Yards may be paved with 2½-inch Yorkshire paving, or such other as the place affords, as in common use. The same to basement stories.

To fit up the wine cellar with bins, as per drawing, with 3-inch Yorkshire stone shelves (some prefer slate), fairly tooled, and set in Parker's cement.

To provide and fix a warm bath of veined marble; render waterproof by being properly set in Dutch tar, and plugged and cramped with copper at the joints, with all requisite finishing. A marble step round two sides of the bath. Cut all holes

**MASON.**

necessary for laying on the water. A bath may be similarly made of slate, which is of course much cheaper.

Where iron girders are used, describe . . . pieces of granite street curb, each . . . feet long, to receive the ends of the cast iron girders.

Where chimneys project without support from below, corbels must be described proportioned to the weight they have to carry. The best corbel, however, is the gradual projection of the work by inverted steps, which, if there be height to hide them, should always be the mode of execution.

Cellar doorways should have in each of them three pieces of Portland or other such stone, 18 inches wide, 18 inches long, and 9 inches high, cut out to receive the hinges and rim of the lock.

All fire-places should have back hearths of 2½-inch rubbed Yorkshire stone.

The commonest chimney-pieces that can be described are of 1½-inch Portland, jambs, mantels, and shelves, 6 inches wide; slabs of 2-inch Portland stone, 20 inches wide.

For butler's and housekeeper's rooms drawings are usually given. They may be of Portland stone slabs, 2 inches thick, 4 feet long, and 1 foot 8 inches wide.

For a kitchen chimney, describe jambs and mantle of 2-inch Portland stone, 10 (or 12) inches wide, with a slab of 2½-inch rubbed Yorkshire stone. The mantle to be in one piece.

For the several rooms where marble chimney-pieces are to be placed, chimney-pieces are described to be provided of a given value, varying in the less important to the best apartments, from eight or ten up to 100 guineas or more in value, of such marble as the employer may select: but if the working drawings have been fully prepared, this is a matter which need not be left in uncertainty. It must always be provided in the specification that the slabs are included, and that the price is or is not (as the case may be) to include the carriage and fixing.

Sinks of Portland or other stones, 7 inches thick (describing the size required), to be provided and fixed as shown in the drawings, with holes cut for the grating and socket pipe, and fixed with all requisite bearers complete.

Sink stones to be provided where shown on the plan. The joints generally are to be where exhibited on the drawings, and the work is to be left perfectly cleaned off, all necessary joggles, joints, rebates, moulded, sunk, weathered and throated works, grooves, chases, holes, back joints, and fair edges, that may be necessary in any part of the work, and all jobbing, though not particularly mentioned under the several heads, is to be performed that may be requisite for the execution of the building, and all the work is to be well cleaned off before delivering it up. The whole of the work is to be warranted perfect, and any damage that may occur to it by reason of frost or settlement within two years after the completion of the building is to be repaired, under the architect's direction, at the sole expense of the contractor.

All mortar is to be of the same quality as that described in the bricklayer's work.

The contractor is to provide lead to run the cramps and joints.

In works within the bills of mortality, the contractor is to pay the expense, under the commissioners of sewers or paving, as the case may be, of making good the street paving to the areas, plinths, and steps abutting thereon.

To provide and fix under the contract . . . cubic feet of . . . stone, including plain work and setting thereto, also . . . superficial feet of 2½-inch Yorkshire paving, laid in regular courses; and in case the whole or any part of either or both should not be wanted, the quantity not used or directed shall be deducted from the amount of the consideration of the contract after the rate of . . . per foot of cubic stone and . . . per foot superficial for the Yorkshire paving, including the workmanship and fixing thereof.

In stables, granite should be provided to receive the heel-posts if cast-iron be not employed, and at the piers of gates, hinge and spur stones, the latter, of granite, if to be had, should be described. The caps and bars of the last can be described only with reference to the drawings of them.

The paving of stables and their courts is described thus: Prepare the ground for paving (stating where) with good and sufficient hard materials, and pave it with Aberdeen granite paving, properly dressed and sorted, 8 inches deep and 5 inches wide at the top and bottom thereof. The whole to be laid with good currents upon a layer 4 inches at least in thickness of good rough gravel, the joints of the surface to be run with stone lime and river sand grouting. It is to be well rammed, and the contractor is to relay, at his own expense, all such parts as may sink within eighteen months of the work being completed.

Where the work is within the bills of mortality, or within a town, specify that a sufficient boarding is to be erected for enclosing the premises during the execution of the

**MASON.**

works, which is to be removed and carried away when they are complete. So, also, all shoring is to be provided, if the works be alterations, or the adjoining buildings may be injured by carrying them into effect. The shoring is to be performed in a safe, scientific, and workmanlike manner, of the fronts, floors, or otherwise, as the case may be.

**2285. CARPENTER AND JOINER.** Where the extent of the works requires a clerk of the works: a direction must be given to provide, erect, and maintain, during their performance, a temporary office for the clerk of the works, with all appurtenances complete, with stool, table, and all other requisite furniture.

All materials requisite for completion of the buildings according to the drawings are to be provided by the contractor. The oak is to be of English growth; the timber not specified of oak is to be of the best Dantzic, Riga, or Memel yellow fir. No American, Swedish, or Scotch fir to be used in any part of the building. All the floors and joiner's work are, except where otherwise directed, to be of the best Christiana deals. The timbers and deals are to be cut square, entirely free from sapwood, shakes, large knots, and all other defects. If any part or parts of the joiner's work should shrink or fly within eighteen months from the finishing and fixing the same, the contractor is to take down, refix, and make good the same, together with all works that may be affected thereby, at his own expense.

No joists, rafters, or quarters are in any case, unless particularly so directed, to be more than 12 inches clear distance from one another.

To provide and fix, ease, and strike all centering and turning pieces for the vaults, arches, trimmers, and other works. Provide all temporary shores that may be necessary. Fix all iron-work of every description. Provide and fix all necessary templets, linings, blocks, stops, casings, beads, springing fillets, angle staffs, grounds, linings, backings, furrings, cappings, and other finishings incident to carpenters' and joiners' works, together with all necessary grooving, rebating, framing, tonguing, housing, beading, mitring, framing, and other workmanship necessary for completing the works.

To provide good and secure casing for all the stone dressings, to protect the same from injury during the execution of the works; and any accident arising from neglect in this respect is to be made good at the expense of the carpenter.

Bond timber. One tier is generally enough for basement story.

Two tiers in the other floors, unless very lofty.

One tier in the upper story.

4 inches by  $2\frac{1}{2}$  inches all around the walls, except where intercepted by the chimneys, to be lapped together, where joints occur, at least 6 inches, and to be properly spiked together. Party walls may be bonded with iron hooping, if thought proper, for a greater security against fire.

To find and fix all wood bricks for fixing the finishings to.

Provide and fix all lintels, and filling in lintels that may be necessary to the several openings: each to be 4 inches high, of the width of the brick work, and 16 inches longer than the opening.

Two small lintels will do if the width of the sofite be considerable, and arches as directed in the bricklayer's work be turned.

For ground or rather basement floors, walls are brought up for receiving oak sleepers, 5 by 3 inches; on which fir joists  $4\frac{1}{2}$  by  $2\frac{1}{2}$  are generally the scantlings employed.

For other floors. Wall plates 6 by 4 are described.

Girders	-	} All which, with their requisite scantlings, will be found in Practical Carpentry. (2013, <i>et seq.</i> )
Joists of all descriptions, according to the kind of floor	-	
Trimmers and trimming joists	-	
Cradling to the girders and such parts as may be necessary to form panels and coffers on the under side for the ceiling, if such be practised.	-	

Where it is necessary to truss the girders, that must be stated.

Cock down all girders on the wall plates. Pin bridging joists to binders with  $\frac{3}{4}$ -inch oak pins.

For roofs, wall plates should be at least 6 inches by 6 inches.

For the different timbers of the several sorts of roofs, the reader will refer to the section on Practical Carpentry, where they are described, and scantlings given of works that have been executed. (2027, *et seq.*) Ceiling joists also to be described.

To what is there found, we may add, that hips and ridges rounded for lead ought to be 10 by 2.

**CARPENTER AND JOINER.**

Where close boarding is used, it should not be less than  $\frac{3}{4}$  to an inch thick. If battens for slating, they should be  $2\frac{1}{2}$  inches wide; the first should be nailed with eightpenny nails. Provide lear boards.

We prefer, on many accounts, and, indeed, ourselves usually adopt, the Italian method of laying the rafters horizontally as so many purlines. For the boarding thus lying lengthwise towards the gable, any wet that may find its way on to it from defective slates or lead, is not apt to lodge against and rot the edges.

*Fluts* are described with wall plates usually 6 by 6. Trimmers and trimming joists against chimneys, and where skylights occur; and  $1\frac{1}{4}$  inch yellow deal boarding, listed, free from sapwood, laid with a current of  $1\frac{1}{2}$ -inch to 10 feet lineal, with  $2\frac{1}{2}$  drips to heading joints, of lead rolls to longitudinal joints, and inch yellow deal risers not less than 4 inches wide next the gutter

Gutters to the roof or roofs are to be as shown on the plan, with inch yellow deal bottoms on strong fir bearers, and laid with a current of  $1\frac{1}{2}$  inches to every 10 feet;  $2\frac{1}{2}$  rebated drips, and at the sides to have  $\frac{3}{4}$ -inch deal lear boards, 9 inches wide. Gutter boards are rarely more than  $1\frac{1}{2}$  inch thick.

Gutter plates, if any, to be described, but they should never be used without support from below.

Trim for trap doors, if any, leading to the roof, and provide and fix dormers with all necessary framing.

Checks, doors, beaded stops and linings, and ironmongery. Boarding for slating or lead to top and checks, as the case may be.

Dormers may be similarly described for windows in the roof.

Quartered partitions, where shown on the plan, with heads and sills 4 inches by 4 inches. Ties above the doors 4 inches by 5 inches. Posts 4 inches by  $3\frac{1}{2}$  inches.

Braces or struts 3 inches square. Quarters 4 inches by 2 inches, and three tiers of interties, 1 inch by  $2\frac{1}{2}$  inches. In cases where partitions are to be trussed for carrying either their own or some additional weight, reference must be made to drawings.

To put to . . . floors (or to the whole if desired) *sounding boarding* of  $\frac{3}{4}$ -inch deal, chopped and fixed upon fillets to receive the pugging.

All external walls should be described to be battened. The thickness of the battens is usually from  $\frac{3}{4}$ -inch to  $1\frac{1}{4}$ -inch, their widths  $2\frac{1}{4}$  inches, and they are placed from 7 to 12 inches apart. If no bond timber to nail them to, plugs must be let into the walls.

Bracketing and cradling is usually, for cornices, cones, &c.,  $1\frac{1}{4}$  inch thick; for entablatures, circular soffits, and waggon-headed ceilings,  $1\frac{1}{2}$  to 2 inches thick.

All bearers to be fixed and provided as shall be necessary.

Weather boarding of the best sort is described as 3-inch yellow deal, wrought, or wrought and beaded.

Luffer boarding ought to be of 1-inch deal, wrought two sides and splayed.

Warehouse posts must be described with their relation to the weight they are to carry (see *Mechanical Carpentry*, 1600, *et seq.*), the caps to them should be long, so that they may not press into the girders, and, if practicable, iron dowels should pass through the girders to catch the bases of the posts in the floor above.

In ordinary cases fir story are about 9 inches square. Oak caps 3 feet long, with splayed ends 9 by 6. Floors are usually rough, not less than  $1\frac{1}{2}$ -inch deal rebated.

Water trunks are made of sizes from 4 to 6 inches or more square, of  $\frac{3}{4}$ -inch to  $1\frac{1}{4}$ -inch deal. They are always to be described as pitched and fixed complete, with hopper heads and shoes, wall hooks, holdfasts, &c.

*Park paling* is of the following varieties, and must be described accordingly:—

4-foot oak cleft pales, 2 arris rails and oak posts.

5-foot oak cleft pales, 2 arris rails and oak posts.

6-foot oak cleft pales, 3 arris rails and oak posts.

If there is to be an oak plank at the bottom, and oak capping at top, they must be specially mentioned.

To provide and fix . . . cubic feet of Baltic yellow fir timber, with all labour thereto, beyond the quantity necessary for the work herein described, to be used in such additional works as may be directed by the architect; and if the whole or any part thereof should not be ordered, the same shall be deducted from the amount of the consideration of the contract, after the rate of . . . per foot cube. All additional fir, if any should be ordered, is to be taken at the like price of . . . per foot cube.

The varieties of *floors* are as follow, each set of thicknesses being enumerated in the order of their increasing value. Batten floors are for better rooms.

## CARPENTER AND JOINER.

- $\frac{3}{4}$ -inch *white* deal, rough, with edges shot.
- $\frac{3}{4}$ -inch *white* deal, wrought, and laid folding.
- $\frac{3}{4}$ -inch *yellow* deal, rough, with edges shot.
- $\frac{3}{4}$ -inch *yellow* deal, wrought, and laid folding.
- $\frac{3}{4}$ -inch *white* deal batten floor, wrought, and laid folding.
- $\frac{3}{4}$ -inch *yellow* deal batten floor, wrought, and laid folding.
- 1-inch *white* deal, rough edges shot.
- 1-inch *white* deal, wrought, and laid folding.
- 1-inch *white* deal, wrought, and laid straight, joint and splayed headings.
- 1-inch *yellow* deal, rough edges shot.
- 1-inch *yellow* deal, wrought, and laid folding.
- 1-inch *yellow* deal, wrought, and laid straight, joint and splayed headings.
- 1-inch *white* deal batten floor, wrought, and laid folding.
- 1-inch *white* deal batten floor, wrought, and laid straight, joint and splayed headings.
- 1-inch *yellow* deal batten floor, wrought, and laid folding.
- 1-inch *yellow* deal batten floor, wrought, and laid straight, joint and splayed headings.
- 1 $\frac{1}{4}$ -inch *white* deal, rough edges shot.
- 1 $\frac{1}{4}$ -inch *white* deal, wrought, and laid folding.
- 1 $\frac{1}{4}$ -inch *white* deal, wrought, straight joint, and splayed headings.
- 1 $\frac{1}{4}$ -inch *yellow* deal, rough edges shot.
- 1 $\frac{1}{4}$ -inch *yellow* deal, wrought, and laid folding.
- 1 $\frac{1}{4}$ -inch *yellow* deal, wrought, straight joint, and splayed headings.
- 1 $\frac{1}{4}$ -inch *white* deal batten floor, straight joint, and splayed headings.
- 1 $\frac{1}{4}$ -inch *white* deal batten floor, straight joint edge nailed, and splayed headings.
- 1 $\frac{1}{4}$ -inch *yellow* deal batten floor, straight joint, and splayed headings.
- 1 $\frac{1}{4}$ -inch *yellow* deal batten floor, straight joint, edge nailed, and tongued headings.
- 1 $\frac{1}{2}$ -inch *white* deal batten floor, edge nailed, and tongued headings.
- 1 $\frac{1}{2}$ -inch *yellow* deal batten floor, edge nailed, and tongued headings.
- 1 $\frac{1}{2}$ -inch *yellow* deal batten floor, dowelled with oak dowels, with mitred and glued borders.
- 1 $\frac{1}{2}$ -inch *yellow* deal, clean batten floor, dowelled with oak dowels, with mitred and glued borders.

*Warehouse floors* are of

- 1 $\frac{1}{2}$ -inch *yellow* deal, rough edges shot.
- 1 $\frac{1}{2}$ -inch *yellow* deal, wrought, and laid folding.
- 1 $\frac{1}{2}$ -inch *yellow* deal, wrought, and straight joint, and splayed headings.
- 2-inch *yellow* deal, rough edges shot.
- 2-inch *yellow* deal, wrought, and laid folding.
- 2-inch *yellow* deal, wrought, and laid straight, joint and splayed headings.

All these last may be ploughed, rebated, and feather-tongued.

The floors of inlaid or *parquetry* work must form, when to be provided, special subjects of specification; they must be described according to drawings, on which are to be marked the different woods to be used in their formation.

The varieties of *skirtings* are classed as under, beginning with the commonest sort: —

- $\frac{1}{2}$ -inch deal square skirting.
- $\frac{3}{4}$ -inch deal square skirting.
- $\frac{1}{2}$ -inch deal torus skirting.
- 1-inch deal square skirting.
- 1-inch deal square skirting, rebated, and backed plinth, with fillet nailed to floor.
- 1-inch deal torus skirting.
- 1 $\frac{1}{4}$ -inch deal square skirting.
- 1 $\frac{1}{4}$ -inch deal torus skirting.
- 1 $\frac{1}{2}$ -inch deal torus skirting, rebated, and backed plinth, with fillet nailed to floor.

If any of these, as to stairs for instance, are raking, and to be scribed to steps, they must be so described, and so if any of them are to be ramped, and similarly if they are to be scribed to moulded nosings, as also if they be circular on the plan.

*Dados* in their varieties are as follow, premising that they are nailed to grounds which should be mentioned.

- $\frac{3}{4}$ -inch deal keyed.
- 1-inch deal keyed.
- 1 $\frac{1}{4}$ -inch deal keyed.
- 1 $\frac{1}{4}$ -inch deal keyed, ploughed, and tongued.
- 1 $\frac{1}{4}$ -inch deal keyed, feather-tongued.

CARPENTER AND JOINER.

Scribed to steps, circular on plan, and wreathed, or ramped : those matters must be mentioned.

Of *wainscoting* with fascia and skirting, the different kinds are subjoined in the order of their quality.

- |                                    |  |
|------------------------------------|--|
| 1-inch deal, square framed         | } The number of panels high to be specified. |
| 1-inch deal, square framed dwarf   |  |
| 1½-inch deal, square framed        |  |
| 1½-inch deal, square framed, dwarf |  |
| 1½-inch deal, bead butt or moulded |  |
| 1½-inch deal, bead butt            |  |
| 1½-inch deal, bead flush           |  |

When any of these are raking, or to have a beaded or moulded capping, or both or either, such must be specified.

*Partitions* of deal for the division of rooms are only used in taverns and the like ; but where they are wanted, as for a mere separation in servants' rooms, they may be employed. Their varieties are —

- |  |                                      |
|--|--------------------------------------|
| 1-inch deal board, and braced with ½-inch panels.      | } These are scarcely to be employed. |
| 1½-inch deal, braced with ¾-inch panels.               |                                      |
| 1½-inch deal, rough, and ledged edges shot.            |                                      |
| 1½-inch deal, wrought both sides, and ploughed.        |                                      |
| 1½-inch deal, wrought both sides, tongued, and beaded. |                                      |
| 1½-inch, square framed.                                |                                      |
| 1½-inch, square framed.                                |                                      |
| 1½-inch, bead butt, moulded, and square.               |                                      |
| 1½-inch, bead flush and square.                        |                                      |
| 1½-inch, moulded on both sides.                        |                                      |
| 2-inch, square framed.                                 |                                      |
| 2-inch, bead butt or moulded and square.               |                                      |
| 2-inch, bead flush and square.                         |                                      |
| 2-inch, moulded on both sides.                         |                                      |
| 2-inch, moulded and bead flush.                        |                                      |
| 2-inch, bead flush and bead butt.                      |                                      |
| 2-inch, bead flush on both sides.                      |                                      |

These, as well as any preceding and following parts of a specification, will, of course, have reference to what is wanted in the design which it is the architect's object to describe in such specification.

*Grounds.* — We have mentioned grounds generally (§166.); but it may be as well here to insert their several sorts : for instance, —

Those of ¾-inch deal, of 1-inch deal, of 1½-inch deal, of 1½-inch deal, and whether circular ; also 1-inch, 1¼-inch, and 1½-inch skeleton grounds, which it is, perhaps, for security against extras, as well as repeat.

*Door cases* are usually employed on basement stories, and should be of oak, though fir is constantly used for them. They fit into the brickwork, and are usually about 5 by 5 inches, and they should be tenoned (the tenon being well pitched or set in white lead) into the stone step, on which they ought to be placed ; for the sill, into which it is the practice to place them, soon rots, however good the material.

*Door linings and their softes.* — These are either plain or framed, the former being of the commoner sort, and the latter for better work and places. They may be enumerated as follow : —

- 1-inch deal, single rebated.
- 1-inch deal, double rebated (that is, so that the door may hang on either side).
- 1½-inch deal, single rebated.
- 1½-inch deal, double rebated.
- 1½-inch deal, single rebated.
- 1½-inch deal, double rebated.

Either of the foregoing, if to be beaded on the edge, must be so described. Of framed linings and softes for doors there are —

- 1½-inch, square framed in one panel and double rebated.
- 1½-inch, square framed in one panel and double rebated, bead butt or moulded.
- 1½-inch, square framed in one panel and double rebated, bead flush.
- 1½-inch, square framed in one panel and double rebated.
- 1½-inch, square framed in one panel and double rebated, bead butt, or moulded.
- 1½-inch, square framed in one panel and double rebated, bead flush.

If the panels in the linings are to be raised, to correspond with panels of doors, they must be so described.

## CARPENTER AND JOINER.

*Framed back linings* are as follow : —

- 1-inch deal, two panel square.
- 1-inch deal, two panel square, bead butt.
- 1-inch deal, three panel square.
- 1-inch deal, three panel square, bead butt.
- 1-inch deal, four panel square.
- 1-inch deal, four panel square, bead butt.

If there be more than four panels, or they are splayed on the plan, or if bead flush, or of a greater thickness, they must be so specified.

*Backs, elbows, and sofites* to windows are described as —

- 1-inch deal, keyed.
- 1-inch deal, keyed, framed square.
- $1\frac{1}{4}$ -inch deal, framed square.
- $1\frac{1}{4}$ -inch deal, framed square, moulded, or bead butt.
- $1\frac{1}{4}$ -inch deal, framed square, bead flush.
- $1\frac{1}{4}$ -inch deal, square framed sofit, with one edge circular. } Applicable to bay win-
- $1\frac{1}{4}$ -inch deal, square framed sofit, with two edges circular. } dows.
- $1\frac{1}{2}$ -inch deal, square framed sofit, moulded, or bead butt.
- $1\frac{1}{2}$ -inch deal, framed square.
- $1\frac{1}{2}$ -inch deal, framed square, moulded, or bead butt.
- $1\frac{1}{2}$ -inch deal, framed square, moulded, or bead flush.

If any of these are splayed, fancy moulded, and with cappings, when also they are circular on the plan, they must be so particularly specified, inasmuch as the price is thereby enhanced.

*Boxings for shutters* are of the following varieties : —

- 1-inch deal, splayed boxings.
- 1-inch deal, proper boxings.
- $1\frac{1}{4}$ -inch deal, splayed boxings.
- $1\frac{1}{4}$ -inch deal, proper boxings.
- $1\frac{1}{4}$ -inch deal, boxings with circular head.
- 1-inch deal, boxings for sliding shutters, with pulley pieces, beads, fillets, and grooves, complete.
- $1\frac{1}{4}$ -inch deal, boxings for sliding shutters, with pulley pieces, beads, fillets, and grooves, complete.

These, if to be double hung, must be so described.

*Window shutters.* — As in the foregoing parts of a specification, we shall proceed from the common to the better sorts.

- $\frac{3}{4}$ -inch deal, ledged or clamped.
- $\frac{3}{4}$ -inch deal, ledged, or clamped, in two heights.
- 1-inch deal, clamped.
- 1-inch deal, clamped in two heights.
- 1-inch deal, clamped in two heights, one panel, bead butt, and square.
- 1-inch deal, clamped in two heights, one panel, bead flush, and square.
- 1-inch deal, clamped in two heights, one panel, bead flush, and bead butt.
- $1\frac{1}{2}$ -inch deal, two panels square.
- $1\frac{1}{2}$ -inch deal, two panels square, in two heights.
- $1\frac{1}{2}$ -inch deal, two panels square, in two heights, moulded, or bead butt, and square.
- $1\frac{1}{2}$ -inch deal, two panels square, in two heights, bead flush, and square.
- $1\frac{1}{2}$ -inch deal, two panels square, in two heights, bead flush, and bead butt.

These may be described of  $1\frac{1}{2}$ -inch deal ; but the back flaps need not be more than one inch, and the additional panels in height, projecting mouldings, if any, and other variations from the general description, must be mentioned.

*Sliding shutters* are to be described in their varieties, as follow : —

- 1-inch deal, two panels square, hung with lines and weights.
- $1\frac{1}{4}$ -inch deal, two panels square, hung with lines and weights.
- $1\frac{1}{4}$ -inch deal, bead butt and square, hung with lines and weights.
- $1\frac{1}{4}$ -inch deal, bead flush and square, hung with lines and weights.
- $1\frac{1}{4}$ -inch deal, bead butt and moulded, hung with lines and weights.
- $1\frac{1}{4}$ -inch deal, bead flush and bead butt, hung with lines and weights.

These, if of  $1\frac{1}{2}$ -inch deal, and if more panels in height, must be so described ; so also if they are circular on the plan ; and if patent lines are to be used for the hanging, they must be mentioned.

*Outside shutters*, now rarely used, even in the provinces, except for shop fronts, must be mentioned, to make our description complete ; they are of

- $1\frac{1}{4}$ -inch deal, three panels, bead butt and square.
- $1\frac{1}{4}$ -inch deal, three panels bead flush and square.

**CARPENTER AND JOINER.**

1½-inch deal, three panels, bead flush and bead butt.

1½-inch deal, three panels, bead flush on both sides.

1½-inch deal, three panels, bead butt and square.

1½-inch deal, three panels, bead flush and square.

1½-inch deal, three panels, bead flush and bead butt.

If these are circular on the plan, or contain more than three panels in height, the specification must so state.

*Staircases* are described as under, beginning with the commonest.

1-inch yellow deal, steps, risers, and carriages.

1½-inch deal, steps, inch risers, and carriage.

1½-inch deal, steps and risers glued up and blocked to close string moulded nosings, and two fir carriages.

1½-inch deal, steps and risers mitred to cut string, and dovetailed to balusters.

1½-inch deal, steps to winders, mitred to cut string, and dovetailed to balusters, one end circular.

1½-inch deal, steps to winders, mitred to cut string, and dovetailed to balusters, both ends circular.

If the risers are to be tongued to the steps, if feather jointed, or if of clean deal, such must be stated in the specification.

1½-inch deal, wrought steps, risers, and strong carriage.

2-inch deal, wrought steps, risers, and strong carriage.

1½-inch oak, treads and risers mitred to string and dovetailed with fir carriage (with solid quarter ends to steps if required), also curtailed step and riser (2187, *et seq.*), returned moulded and mitred nosings, circular, if necessary, with cut plain (and circular) brackets.

Housings to ends of steps and winders, and the same to moulded nosings and circular ends, are to be specified.

*String boards to staircases* to receive the ceilings of stairs (or strings as they are called), are—

1-inch deal, framed.

1-inch deal, framed, rebated, and beaded.

1½-inch deal, framed string board.

1½-inch deal, framed string board, sunk and beaded.

1½-inch deal, framed string board, sunk, beaded, and moulded.

1½-inch deal, framed string board, sunk, beaded, moulded, and mitred to risers.

1½-inch deal, wreathed outside, string glued upright, rebated, and beaded.

1½-inch deal, wreathed outside, string glued upright, rebated, beaded, and sunk.

1½-inch deal, wreathed outside, string glued upright, rebated, beaded, sunk, and moulded.

If the string is to be glued up in thicknesses, that must be specified, as also all plain or moulded circular cuttings or ramps.

1-inch deal, plain wall string.

1½-inch deal, plain wall string.

1½-inch deal, plain wall string.

2-inch deal, plain wall string.

If moulded, to be so described.

*Handrails to staircases* are described as—

1½-inch deal, plain wreathed.

1½-inch deal, plain wreathed.

2-inch deal, plain wreathed.

If moulded, state so.

Deal moulded 2½-inch handrail.

Deal moulded 2½-inch handrail, ramped (or circular where required).

Deal moulded 2½-inch handrail, wreathed and twisted.

Honduras mahogany or wainscot moulded handrail. To be described if necessary with ramps, circular and twist, or with scroll and twist to the curtail step.

Spanish mahogany handrail is also similarly described.

If grooved for balusters, circular, or sunk for iron cores, mitred and turned caps, such to be mentioned.

*Balusters and newels* are described—

Deal square framed newels.

Deal square framed newels, chamfered.

Single and double turnings to newels to be mentioned, as also pendent drops, when used.

Deal square bar balusters.

Deal square bar balusters, dovetailed.

## CARPENTER AND JOINER.

Turned balusters according to drawing, when necessary.

Planceer rounded on both edges, or-moulded, as the case may be.

Fix all iron balusters and stays.

*Sash frames* are of great variety, whereof the following is a list : —

Deal cased frame for  $1\frac{1}{2}$ -inch sashes, oak sunk sill with brass pulleys for single hanging.

Ditto, for double hanging.

Ditto, ditto, with circular head.

Ditto, circular on plan (and with circular head, when required).

Deal cased frames for 2-inch sashes, oak sunk sills with brass pulleys prepared for single hanging.

Ditto, prepared for double hanging.

If circular on head and plan, or either, such to be specified.

Deal-cased frames for 2-inch sashes, oak sunk sills with wainscot pulley pieces and beads, brass axle pulleys prepared to hang double.

If circular on head and plan, or either, such to be specified.

Deal cased frames for 2-inch sashes, oak sunk sills, mahogany pulley pieces and beads with brass axle pulleys, prepared to hang double.

The same description holds for  $2\frac{1}{2}$ -inch sashes.

If, as before, circular on head and plan, or either, such to be mentioned.

*Venetian frames* are described as —

Deal cased frames for  $1\frac{1}{2}$ -inch sashes, oak sunk sills, and prepared to hang single or double, as the case may be.

If circular on plan and head, or either, specify the same.

The above description for  $1\frac{1}{2}$ -inch serves also for 2-inch and  $2\frac{1}{2}$ -inch sashes.

If wainscot or mahogany, they must be so described.

*Casement frames* for French casements : —

Fir solid wrought frames for  $1\frac{1}{2}$ -inch French casements, with oak sunk sills (plain or circular on the plan, as the case may be).

Fir solid wrought frames for 2-inch French casements and oak sunk sills (as before).

Fir solid wrought frames for 2-inch French casements and oak sunk sills (as before), with wainscot or mahogany styles and beads as may be correspondent with the sashes.

The same for  $2\frac{1}{2}$ -inch sashes.

*Fanlight frames* over doors, which have nearly lost their employment from square lights having superseded them, are of —

$1\frac{1}{2}$ -inch deal frames, square framed.

Ditto, semicircular head.

2-inch deal, square framed.

Ditto, semicircular head.

If elliptical, so describe them.

*Sashes* are to be described as follows : —

$1\frac{1}{2}$ -inch deal ovolo (describe whether with circular head or circular on plan, if so).

2-inch deal ovolo (ditto).

2-inch deal astragal and hollow (ditto).

$2\frac{1}{2}$ -inch deal astragal and hollow (ditto).

The above, if of wainscot, Honduras or Spanish mahogany, are to be so described, as also that they are to be hung single or double, as the case may be, with patent lines and iron weights, and patent sash-fastenings complete.

*French casements* are usually described as follows : —

2-inch deal ovolo casements. If with marginal lights or circular on plan, or both, describe them so ; or if with astragal and hollow.

The same of  $2\frac{1}{2}$ -inch, with the same modifications as in preceding article.

If either of the above be of wainscot, Honduras or Spanish mahogany, let them be so described.

It is usual to describe with these the hanging, which is commonly with 4-inch iron or brass butt hinges, and the species of fastening which it is common to place, at a sum varying from five to twenty shillings. When the turning Espaniolette fastenings are used, they must be particularly specified.

*Shop-window sashes* vary so much that we shall merely observe of their thicknesses, they are from  $1\frac{1}{2}$  to  $2\frac{1}{2}$  inches, and in the present extravagant rage for novelty among tradesmen, there is no end to the forms of their horizontal sections ; — nothing, however *outré*, would be considered too extravagant for these people, and all that we can do is to say that, after describing their thickness, they are to be executed according to the drawings. In subjects of this kind, too, the *stall*

CARPENTER AND JOINER.

*board*, and other fittings of the like nature, are to be specified in all, whereof the best way is to describe with reference to such drawings.

*Friezes and cradling for cornices* should always be referred to drawings, specifying generally their height.

*Skylights*, now usually made of metal; but if not, describe as follows:—

1½-inch deal ovolo skylight (if hipped, and with cross bars, state such).

2-inch deal ditto (ditto).

2½-inch ditto (ditto).

If astragal and hollow, or if of oak, such to be specified.

*Kerbs for skylights* are to be described—

1½-inch deal kerbs to circular skylights in two thicknesses, bevelled and chamfered.

2-inch ditto ditto.

2½-inch ditto ditto.

If elliptical, to be so specified.

*Doors* we shall, as in the preceding articles, describe, beginning with the commonest sort, for out-houses and the like.

¾-inch ledged wrought deal door.

Ditto, ploughed, tongued, and beaded.

1-inch wrought deal ledged ditto.

Ditto, ploughed, tongued, and beaded.

1½-inch wrought deal ledged ditto.

Ditto, ploughed, tongued, and beaded.

1½-inch and 2-inch deal ledged doors are similarly described.

These doors may be hung with  $\frac{1}{2}$ -L or cross garnet hinges or with butt hinges, and with bolts, locks, latches, and other fastenings, as the case may require. External doors with 4-inch butts, if that be the sort used, and internal ones with 3½-inch butts.

*Gates and coach-house doors* are specified as—

2-inch deal, framed and braced, filled in with 2-inch deal, and ploughed, tongued, and beaded.

The same, filled in with battens.

2½-inch deal, framed and braced, filled in with 1-inch deal, ploughed, tongued, and beaded.

Ditto, filled in with battens.

If filled in with whole deal, it must be so specified.

2-inch deal bead butt and square gates, in eight panels.

2-inch deal bead butt and square gates, beadflush and square.

2-inch deal bead butt and square gates, bead flush on both sides.

If with more panels, or framed with a wicket, such must be specified.

The hanging of gates, and their hinges and fastenings, may be inserted according to the occasion of the work, at from 10*l.* to 15*l.* or even 20*l.*, which may be declared in the specification as to the value at which they are to be provided.

1-inch deal 1-panel square doors.

1-inch deal 1-panel square doors, folding.

The above are rarely used: we shall now, therefore, proceed by the number of panels, up to 6-panel doors, beyond which they are to be so particularly specified, or with reference to drawings.

1½-inch, 2 panels, square.

1½-inch, 2 panels, bead butt and square.

1½-inch, 2 panels, bead flush and square.

1½-inch, 2 panels, moulded and square.

1½-inch, 2 panels, bead butt on both sides.

1½-inch, 2 panels, bead butt and bead flush.

1½-inch, 2 panels, bead butt and moulded.

1½-inch, 2 panels, bead flush on both sides.

1½-inch, 2 panels, bead flush and moulded.

1½-inch, 2 panels, moulded on both sides.

When hung folding, to be so specified.

1½-inch deal, 2 panels, square.

1½-inch deal, 2 panels, bead butt and square.

1½-inch deal, 2 panels, bead flush and square.

1½-inch deal, 2 panels, moulded and square.

1½-inch deal, 2 panels, bead butt on both sides.

1½-inch deal, 2 panels, bead butt and bead flush.

1½-inch deal, 2 panels, bead butt and moulded.

1½-inch deal, 2 panels, bead flush on both sides.

## CARPENTER AND JOINER.

1½-inch deal, 2 panels, bead flush and moulded.

1½-inch deal, 2 panels, moulded on both sides.

2-inch deal, 2 panels, square.

2-inch deal, 2 panels, bead butt and square.

2-inch deal, 2 panels, bead flush and square.

2-inch deal, 2 panels, moulded and square.

2-inch deal, 2 panels, bead butt on both sides.

2-inch deal, 2 panels, bead butt and bead flush.

2-inch deal, 2 panels, bead butt and moulded.

2-inch deal, 2 panels, bead flush on both sides.

2-inch deal, 2 panels, bead flush and moulded.

2-inch deal, 2 panels, moulded on both sides.

2½-inch deal, 2 panels, square.

2½-inch deal, 2 panels, bead butt and square.

2½-inch deal, 2 panels, bead flush and square.

2½-inch deal, 2 panels, moulded and square.

2½-inch deal, 2 panels, bead butt on both sides.

2½-inch deal, 2 panels, bead butt and bead flush.

2½-inch deal, 2 panels, bead butt and moulded.

2½-inch deal, 2 panels, bead flush on both sides.

2½-inch deal, 2 panels, bead flush and moulded.

2½-inch deal, 2 panels, moulded on both sides.

All these, as well as the following, must be specified as to be hung folding, if the nature of the work so requires.

1½-inch deal, 4 panels, square.

1½-inch deal, 4 panels, bead butt and square.

1½-inch deal, 4 panels, bead flush and square.

1½-inch deal, 4 panels, moulded and square.

1½-inch deal, 4 panels, bead butt on both sides.

1½-inch deal, 4 panels, bead butt and bead flush.

1½-inch deal, 4 panels, bead butt and moulded.

1½-inch deal, 4 panels, bead flush on both sides.

1½-inch deal, 4 panels, bead flush and moulded.

1½-inch deal, 4 panels, moulded on both sides.

2-inch deal, 4 panels, square.

2-inch deal, 4 panels, bead butt and square.

2-inch deal, 4 panels, bead flush and square.

2-inch deal, 4 panels, moulded and square.

2-inch deal, 4 panels, bead butt on both sides.

2-inch deal, 4 panels, bead butt and bead flush.

2-inch deal, 4 panels, bead butt and moulded.

2-inch deal, 4 panels, bead flush on both sides.

2-inch deal, 4 panels, bead flush and moulded.

2-inch deal, 4 panels, moulded on both sides.

2½-inch deal, 4 panels, square.

2½-inch deal, 4 panels, bead butt and square.

2½-inch deal, 4 panels, bead flush and square.

2½-inch deal, 4 panels, moulded and square.

2½-inch deal, 4 panels, square, bead butt on both sides.

2½-inch deal, 4 panels, square, bead butt and bead flush.

2½-inch deal, 4 panels, square, bead butt and moulded.

2½-inch deal, 4 panels, square, bead flush on both sides.

2½-inch deal, 4 panels, square, bead flush and moulded.

2½-inch deal, 4 panels, square, moulded on both sides.

1½-inch deal, 6 panels, square.

1½-inch deal, 6 panels, bead butt and square.

1½-inch deal, 6 panels, bead flush and square.

1½-inch deal, 6 panels, moulded and square.

1½-inch deal, 6 panels, bead butt on both sides.

1½-inch deal, 6 panels, bead butt and bead flush.

1½-inch deal, 6 panels, bead butt and moulded.

1½-inch deal, 6 panels, bead flush on both sides.

1½-inch deal, 6 panels, bead flush and moulded.

1½-inch deal, 6 panels, moulded on both sides.

If the panels of 1½-inch doors are raised, or if double marginal doors, so describe them.

## CARPENTER AND JOINER.

*Wainscot doors* are usually as follow : —

- 1½-inch wainscot, 2 panels, square.
- 1½-inch wainscot, 2 panels, bead flush and square.
- 1½-inch wainscot, 2 panels, moulded and square.
- 1½-inch wainscot, 2 panels, bead flush on both sides.
- 1½-inch wainscot, 2 panels, bead flush and moulded.
- 2-inch wainscot, 2 panels, square.
- 2-inch wainscot, 2 panels, bead flush and square.
- 2-inch wainscot, 2 panels, moulded and square.
- 2-inch wainscot, 2 panels, bead flush on both sides.
- 2-inch wainscot, 2 panels, bead flush and moulded.
- 2½-inch wainscot, 2 panels, square.
- 2½-inch wainscot, 2 panels, bead flush and square.
- 2½-inch wainscot, 2 panels, moulded and square.
- 2½-inch wainscot, 2 panels, bead flush on both sides.
- 2½-inch wainscot, 2 panels, bead flush and moulded.
- 1½-inch wainscot, 4 panels, square.
- 1½-inch wainscot, 4 panels, bead flush and square.
- 1½-inch wainscot, 4 panels, moulded and square.
- 1½-inch wainscot, 4 panels, bead flush both on sides.
- 1½-inch wainscot, 4 panels, bead flush and moulded.
- 1½-inch wainscot, 4 panels, moulded on both sides.
- 2-inch wainscot, 4 panels, square.
- 2-inch wainscot, 4 panels, bead flush and square.
- 2-inch wainscot, 4 panels, moulded and square.
- 2-inch wainscot, 4 panels, bead flush on both sides.
- 2-inch wainscot, 4 panels, bead flush and moulded.
- 2-inch wainscot, 4 panels, moulded both on sides.
- 2½-inch wainscot, 4 panels, square.
- 2½-inch wainscot, 4 panels, bead flush and square.
- 2½-inch wainscot, 4 panels, moulded and square.
- 2½-inch wainscot, 4 panels, bead flush on both sides.
- 2½-inch wainscot, 4 panels, bead flush and moulded.
- 2½-inch wainscot, 4 panels, moulded on both sides.
- 2-inch wainscot, 6 panels, square.
- 2-inch wainscot, 6 panels, bead flush and square.
- 2-inch wainscot, 6 panels, moulded and square.
- 2-inch wainscot, 6 panels, bead flush on both sides.
- 2-inch wainscot, 6 panels, bead flush and moulded.
- 2-inch wainscot, 6 panels, moulded on both sides.
- 2½-inch wainscot, 6 panels, square.
- 2½-inch wainscot, 6 panels, bead flush and square.
- 2½-inch wainscot, 6 panels, moulded and square.
- 2½-inch wainscot, 6 panels, bead flush on both sides.
- 2½-inch wainscot, 6 panels, bead flush and moulded.
- 2½-inch wainscot, 6 panels, moulded on both sides.
- 2-inch wainscot *sash-doors*, with diminished stiles, lower panel moulded, bead flush, with astragal and hollow sash.
- 2-inch wainscot *sash-doors*, with diminished stiles, lower panel moulded, bead flush, with astragal and hollow sash, moulded on both sides.
- 2½-inch wainscot *sash-doors*, diminished stiles, lower panels moulded, and bead flush, with astragal and hollow sash.
- 2½-inch wainscot *sash-doors*, diminished stiles, lower panels moulded, and bead flush, with astragal and hollow sash, moulded on both sides.

If any of these are to be hung folding, double margined, or moulded on the raising, such must be specified.

*Mahogany doors* as follows : —

- 2-inch Honduras mahogany doors, 2 panels, moulded and square.
- 2-inch Honduras mahogany doors, 2 panels, moulded on both sides.
- 2-inch Honduras mahogany doors, 4 panels, moulded and square.
- 2-inch Honduras mahogany doors, 4 panels, moulded on both sides.
- 2-inch Honduras mahogany doors, 6 panels, moulded and square.
- 2-inch Honduras mahogany doors, 6 panels, moulded on both sides.
- 2½-inch Honduras mahogany doors, 4 panels, moulded and square.
- 2½-inch Honduras mahogany doors, 4 panels, moulded on both sides.
- 2½-inch Honduras mahogany doors, 6 panels, moulded and square.

## CARPENTER AND JOINER.

2½-inch Honduras mahogany doors, 6 panels, moulded on both sides.

If any of these are hung folding, with projecting mouldings, or with double margins, it must be so specified. The last set of doors, if required to be of a better description, may be specified of the best Spanish mahogany

2-inch Honduras mahogany sash-door, astragal and hollow bottom, panel moulded and square.

2-inch Honduras mahogany sash-door, astragal and hollow bottom, panel moulded on both sides.

2½-inch Honduras mahogany sash-door, astragal and hollow bottom, panel moulded and square.

2½-inch Honduras mahogany sash-door, astragal and hollow bottom, panel moulded on both sides.

If hung folding, or with double margin, or diminished stiles, to be so specified.

*External doors* are of varieties, as follow : —

2-inch deal, 4 panels, the lower panels bead butt and square, and the upper panels square both sides.

2-inch deal, 4 panels, the lower panels bead butt and square, and the upper panels bead butt on the back.

2-inch deal, 4 panels, the lower panels bead butt and square, and the upper panels bead flush on the back.

If the panels have raised mouldings, specify them.

2½-inch deal, 4 panels, the lower panels bead butt and square, upper panels square on both sides.

2½-inch deal, 4 panels square, bead butt on the back.

2½-inch deal, 4 panels square, bead flush on the back.

Specify raised mouldings, if any.

2-inch deal, 6 panels, lower panels bead butt and square, upper panels square both sides.

2-inch deal, 6 panels, lower panels bead butt and square, upper panels square, bead butt on the back.

Specify raised mouldings, if any.

2½-inch deal, 6 panels, the lower panels bead butt and square, and the upper panels square both sides.

2½-inch deal, 6 panels, the lower panels bead butt and square, and the upper panels square, bead butt on the back.

2½-inch deal, 6 panels, the lower panels bead butt and square, and the upper panels square, bead flush on the back.

If with raised mouldings, so describe them ; also, if double margined, &c.

Any of these external doors, if hung folding, or with circular or curved heads, must be so specified.

*Sash doors* are of the following varieties : —

1½-inch deal, 2 panels, square, diminished stiles, and ovolo sash.

1½-inch deal, 2 panels, bead butt and square, diminished stiles, and ovolo sash.

1½-inch deal, 2 panels, bead flush and square, diminished stiles, and ovolo sash.

1½-inch deal, 2 panels, moulded and square, diminished stiles, and ovolo sash.

1½-inch deal, 2 panels, moulded and bead butt, diminished stiles, and ovolo sash.

1½-inch deal, 2 panels, moulded on both sides, diminished stiles, and ovolo sash.

2-inch deal, 2 panels square, diminished stiles, and ovolo sash.

2-inch deal, 2 panels, bead butt and square, diminished stiles, and ovolo sash.

2-inch deal, 2 panels, bead flush and square, diminished stiles, and ovolo sash.

2-inch deal, 2 panels, moulded and square, diminished stiles, and ovolo sash.

2-inch deal, 2 panels, moulded and bead butt, diminished stiles, and ovolo sash.

2-inch deal, 2 panels, moulded and bead flush, diminished stiles, and ovolo sash.

2-inch deal, 2 panels, moulded on both sides, diminished stiles, and ovolo sash.

2½-inch deal, 2 panels, square, with diminished stiles, and ovolo sash.

2½-inch deal, 2 panels, bead butt and square, diminished stiles, and ovolo sash.

2½-inch deal, 2 panels, bead flush and square, diminished stiles, and ovolo sash.

2½-inch deal, 2 panels, moulded and square, diminished stiles, and ovolo sash.

2½-inch deal, 2 panels, moulded and bead butt, diminished stiles, and ovolo sash.

2½-inch deal, 2 panels, moulded and bead flush, diminished stiles, and ovolo sash.

2½-inch deal, 2 panels, moulded on both sides, diminished stiles, and ovolo sash.

If hung folding, or with marginal lights, to be so described.

It is the practice in describing joiner's work, to specify the ironmongery used with it, that is, the hinges, locks, fastenings, and furniture ; and we have accordingly mentioned the hanging and fastening of common doors, and gates, and coach-house doors

## CARPENTER AND JOINER.

Common framed 4-panel doors are usually hung with  $3\frac{1}{2}$ -inch butts and 7-inch iron rim stock locks. Better doors are hung with 4-inch iron or brass butts, mortice locks and brass nob furniture. Folding doors, if heavy, should have  $4\frac{1}{2}$  or 5-inch brass butts, and if necessary to clear mouldings, they should be hung with projecting brass butts, and should moreover be provided with flush and other bolts, and mortice locks and furniture. Doors of dining, drawing, and other rooms, where they are required to clear the carpet by rising as they open, should have 4 or  $4\frac{1}{2}$ -inch rising joint butts. For closet doors,  $3\frac{1}{2}$ -inch butts are usually described with brass tumbler locks and keys. External doors require the provision of larger locks, which are usually iron rim locks with 10 or 12-inch bright rod bolts, chains, staples, &c. Shutters when hung are with butts, which for the back flaps are of a less size, and spring bar fastenings should be specified to them. Brass nobs to the front flaps.

*Moulded architraves* to doors and windows are described by their width.

*Columns and pilasters* are usually described —

1 $\frac{1}{2}$ -inch deal diminished columns, . . . inches diameter.

1 $\frac{1}{2}$ -inch deal diminished columns, . . . inches diameter.

Pilasters similarly specified. Both one and the other to be glued up and blocked.

If fluted, to be mentioned; as also necking grooves to columns. Caps and bases according to the order, carved or of papier maché, as the expense will allow.

*Entablatures* got out of deal, as per drawing, provide glued, blocked, and fixed with all necessary brackets and grounds.

*Water-closets* are fitted up with 1-inch clean deal (wainscot or mahogany), seats, risers, and clamped flaps, square skirtings, all requisite bearers and pipe-casing; and the joiner is to attend on the plumber while fixing the basins and other work. *Privies* are described as to seats and risers the same as water-closets.

*Cisterns*, internal and external, must have their cistern cases proportioned in thickness to their sizes; thus one about 3 or 3 feet 6 inches long, and 2 feet 9 inches deep, will do on 1 $\frac{1}{2}$ -inch deal dovetailed: it should be described with requisite bearers, and a cover of  $\frac{3}{4}$ -inch deal with a wood handle. For a good-sized external cistern, we should specify, provide and fix a wrought and dovetailed 2-inch deal cistern case, . . . feet long, . . . feet wide, and . . . feet deep in the clear. Find and fix all necessary bearers for the same, together with all other requisite fittings, and further provide a  $\frac{3}{4}$ -inch deal strongly ledged cover, with saddle-back fillets and water channels at each joint, as shall be directed.

*Cisterns for water-closets.*

Each to have cistern cases of 2-inch deal capable of containing 36 cubic feet of water, fixed with strong bearers and ledged covers of  $\frac{3}{4}$ -inch yellow deal tongued and beaded.

*Sinks*, describe as under, when wooden ones lined with lead are used.

1 $\frac{1}{2}$ -inch dovetailed sink, enclosed with 1 $\frac{1}{2}$ -inch deal square-framed front, and door hung with 3-inch butts and other necessary ironmongery.

*Warm bath.*

To be fitted up (of the best Spanish mahogany) with riser, frame, and clamped flap, provided and fixed with all requisite bearers and other fittings and appurtenances.

The flap to be moulded in front, and hung with  $3\frac{1}{2}$ -inch butt hinges, and the riser panelled and moulded as shown in the drawings.

*Dressers.* The following is a specification for a good house.

Provide and fix a dresser in the kitchen, of 2-inch deal, with cross-tongued top 10 feet long and 2 feet 9 inches wide, supported on strong framed legs and bearers. 1-inch deal pot-board and bearers. Six 1 $\frac{1}{2}$ -inch sunk shelves, whose widths are to average 7 inches. Back of the shelves to be of 1-inch deal, wrought, beaded, grooved, and cross-tongued. 1-inch deal top, 14 inches wide, with moulded cornice.

Five drawers with bottoms and dovetailed rims of  $\frac{3}{4}$ -inch deal. The fronts to be of 1-inch deal, beaded. A brass drop handle and a good patent tumbler lock to each drawer, together with all slides, runners, bearers, and other requisite appurtenances.

*Dresser top* for scullery, 1 $\frac{1}{2}$ -inch clean deal, 2 feet 6 inches wide and 6 feet long, cross-tongued and fixed upon strong wrought and framed legs and bearers.

*Plate-rack* for scullery to be provided over the sink, and of the same length. Sink as above described.

*Spit-rack* to be provided over the kitchen chimney, or other convenient place, as may be directed.

*Dwarf closets*, if any are used, may be of 1-inch deal, square framed and moulded in front, the doors to be hung with  $2\frac{1}{2}$ -inch butts, and to have tumbler locks.

*Pipe casings*, wrought and framed, to be provided where necessary, to hide lead pipes of all descriptions, and fronts to unscrew for coming at the pipes in case of defects therein.

## CARPENTER AND JOINER.

*Fittings for larder*, as follow : —

Provide a clean deal dresser top,  $1\frac{1}{2}$  inch thick, 2 feet 6 inches wide, and . . . feet long, to be feather-tongued and fixed on strong framed legs and rails. Two meat rails, 6 feet long, of wrought fir,  $3\frac{1}{2}$  by 2 inches, suspended from wrought iron stirrups. Provide also a hanging shelf, 6 feet long, 10 inches wide, and  $1\frac{1}{4}$  inch thick, to be similarly suspended by wrought iron stirrups.

*Laundry* to be fitted up with  $1\frac{1}{2}$ -inch clean white deal washing troughs, wrought two sides, and splayed and put together with white lead, as shown on drawing.  $1\frac{1}{4}$ -inch deal ironing board, wrought both sides and clamped, properly hung with hinges to a hanging stile. Provide two clothes racks, hung with pulleys and ropes to the ceiling to raise and lower the same.

*Dust bin*, with proper slides, where shown on the plan, to contain 30 feet cube, the whole to be of oak.

*Arris gutters* to eaves should never be of wood : zinc or copper are better materials, and we do not therefore think it necessary to describe them.

*Fittings to shops* are so various that no general description can be given. They must be referred to drawings, and on them the specification should be written. So of *shop fronts*.

*Stable fittings* are specified as follow : —

*Mangers*, &c. 2-inch deal bottoms and  $1\frac{1}{2}$ -inch deal sides. Wrought oak manger-rails, 4 by 3 inches. Wrought, rebated, and rounded oak manger post, 6 by 4 inches, wrought and framed with bearers thereto. Oak heel-posts, wrought, 6 by 5 inches, and groove for partitions. Oak top rails, 5 by 4 inches, grooved and rounded at the top. Oak bottom rails, wrought, 4 by 4 inches, grooved and arris rounded off.  $1\frac{1}{2}$ -inch deal partitions, wrought on both sides, ploughed, tongued, and beaded.  $1\frac{1}{4}$ -inch deal rails on each side, board wide, and the arrisses rounded off.

*Fronts to hay-racks*. Oak standard, 4 by 4 inches, wrought and framed into oak bearer under the manger.  $1\frac{1}{2}$  inch deal fronts framed for the reception of cast-iron hay-racks well secured. Fix fir bearers and 1-inch deal partitions at each end of hay-racks, with fir arris rails 3 inches apart at the bottom of each rack.

*Dressings over stalls* connected with heel-posts. 1-inch deal frieze, wrought joints, feather-tongued, and backings thereto, segmental soffites and keystone in centre of arches. Impost moulding at the springings and moulded cornice to girt about 10 inches.

*Line* the walls to the height of 5 feet with 1-inch yellow deal, wrought, ploughed, tongued, and beaded, with a  $\frac{3}{8}$ -inch beaded capping thereon.

*Churches*. To give general directions for the specification of a church would be impossible.

The principles of its timbering may be collected from what has preceded. *Pewing* is executed as planned on the drawings, of whole deal (generally) square-framed partitions two panels high ;  $1\frac{1}{2}$ -inch framed doors and enclosures one or two panels high, with stiles, munnions, and top rails 3 inches wide, and bottom rails 6 inches wide. The panels of the doors and enclosures should not be more than a board in width, and the framework round them chamfered. The doors are hung with 3-inch butt hinges, and should have brass nob pulpit latches. Capping to the whole of the pewing, grooved and moulded according to drawing. *Pew fittings* are,  $1\frac{1}{2}$ -inch wrought and rounded seats 12 inches wide, with proper bearers and  $1\frac{1}{4}$ -inch cut brackets not more than 3 feet apart. Seats rounded next the pew doors. *Flap-seats* in the galleries to have strong joints. All the pews to have  $\frac{3}{4}$ -inch book boards 6 inches wide, with  $\frac{1}{2}$ -inch rounded capping bearers, and  $\frac{1}{2}$ -inch cut brackets thereunder, not more than 2 feet 6 inches apart, and the ends rounded next the pew doors. If there be an organ, its enclosure and the free seats adjoining it should correspond with the pew enclosures.

*Free seats* of  $1\frac{1}{2}$ -inch deal, as shown in the drawings. The seats to be 11 inches wide, rounded in front. Backs framed with stiles, munnions, and rails,  $3\frac{1}{2}$  inches wide, and the standards, ends, and bearers, according to the drawings. *Children's seats* to be of  $1\frac{1}{4}$ -inch deal, with brackets same thickness, not more than 2 feet 6 inches apart ; at least 8 inches wide, and the flap seats, where they occur, to be hung with strong butts. *Pulpits and reading desks* are usually of  $1\frac{1}{2}$ -inch deal, framed according to drawings, with  $1\frac{1}{4}$ -inch doors, hung with brass hinges and pulpit latches. Whole deal floors on bearers, 1-inch book boards, cappings and bearers. 1-inch clean deal or wainscot steps and risers, moulded returned nosings,  $1\frac{1}{4}$  inch, beaded, sunk and cut string boards, strong bracketed carriages. 1-inch square framed sofite under pulpit floor and stairs, mahogany or wainscot moulded handrail, with caps turned and mitred ; square bar balusters with one in ten of iron ; turned newels to block steps ; seats of  $1\frac{1}{4}$ -inch deal, 13 inches wide, and proper bearers thereto, together with all appurtenances and requisite fittings for executing the drawings.

## CARPENTER AND JOINER.

The carpenter and joiner is to provide all such jobbing work, in following or preceding the other artificers engaged on the works and their appurtenances, as may be requisite for the completion thereof in every respect, without any extra charge.

2286. **FOUNDER, SMITH, AND IRONMONGER.** For describing cast iron girders and columns, reference must be had to Chap. II. Sect. V. (1753, *et seq.*), wherein will be found the method of determining their scantlings—for which no rule can be given that is not dependent on the results there laid down. Having determined the weight to be borne, no girder (and such should be inserted in the specification) should be allowed to be used, that has not been previously tested by *weighing* it at the foundry.

*Cast iron cradles* are sometimes used for openings, which must be described for the particular occasions as they occur.

*Chimney bars* are described usually as follows:—

Provide and fix to kitchen chimney two wrought iron cradle bars, each 2 inches wide and  $\frac{3}{4}$ -inch thick, long enough to extend to the outside of the chimney jambs, and turned up and down at each end. The other chimneys are to have wrought iron chimney bars 3 inches wide and  $\frac{1}{2}$  inch thick.

*Straps, stirrup irons, nuts, bolts, screws, and washers*, together with all other wrought iron work for the roofs and partitions, to be provided, as may be requisite for tying in and securing all carpentry, and the smith is to deliver to and assist the carpenter in fixing or attaching the same.

Where the quantity is uncertain, a given weight beyond the above general direction should be provided in the contract, such part thereof as may not be wanted to be deducted from the accounts after the rate of . . . per cwt.

Provide all necessary cramps of cast and wrought iron, as may be directed, for the mason, the former to be used where the works are exposed to the air.

*Wrought iron doors* to be provided for strong room (or if opening in a party wall), folding, and of the best quality, as shown in drawing; with hinges and proper fastenings, of the value at least of 25*l*.

If *cast iron sashes* are used in any part of a building, they are to be provided with reference to drawings.

*Wedges for underpinning* must be described with reference to the thickness of walls they are to catch: each pair must be at least as long as the wall is thick.

*Balusters to a buck stone staircase and landings* are described—

Wrought iron balusters,  $\frac{3}{4}$  inch square, with turned wrought iron newel equal to  $1\frac{1}{2}$  inch diameter, with rounded handrail of wrought iron  $1\frac{1}{2}$  by  $\frac{1}{2}$  inch. The balusters and newel are to be riveted into the handrail at top, and at the bottom let into the stone work and run with lead.

*Balusters to a principal staircase* are described—

Ornamental cast iron balusters, as shown on the drawings, with top rail of wrought iron  $1\frac{1}{4}$  by  $\frac{1}{2}$  an inch, let into and firmly screwed to the mahogany (or wainscot) handrail. The balusters and newels are to be riveted into the iron rail, and at the bottom they are to be let into the stonework and run with lead

*Balusters of wrought iron* to be provided for strengthening the principal staircase when not of stone. Every tenth baluster to be of wrought iron, properly fastened.

Provide and fix . . . knockers for . . . doors to . . .

*Air bricks* of cast iron to be provided and fixed in the brickwork for the ventilation of the floors.

*Air gratings*, . . . in number, to be provided, 9 inches square, and fixed round the lower part of the walls of the house.

*Area gratings*, . . . to each area (if any there be), to be prepared and fixed of cast iron, with bars  $1\frac{1}{2}$  inch by  $\frac{3}{4}$  of an inch, and not more than  $1\frac{1}{2}$  inch apart. Frames  $1\frac{1}{2}$  inch by 1 inch, and with strong flanges to let into the surrounding stone-work.

*Window guards* of wrought iron to the windows of . . . , and . . . bars to be 1 inch square and 4 inches apart, with framework of iron of the same substance securely fixed to the brickwork.

*Cast iron rain-water pipe*, for a large size stack, is described—

6 inches diameter, to lead from the roof down into the drain. with head and shoe complete.

*Coal plates* (if more than one) of cast iron, with proper fastenings to be fixed over the coal shoot.

*Cast iron ornamental railing*, as per drawing, to the windows, or to the stone balcony in front of the house, as the case may be.

*Air traps* of cast iron to all communications of surface water with drains to be of appropriate size, and provide all gully-hole gratings that may be necessary.

To provide for the carpenter's and joiner's works, and use and fix thereto, besides that

**FOUNDER, SMITH, AND IRONMONGER.**

which has been already described, all requisite spikes, nails, screws, and other proper ironmongery, and all requisite brass work, both to be of the very best quality.

Provide a copper, . . . inches diameter, and stewing stoves as shown on the drawings, with all requisite bars and iron work.

For fittings to stables describe —

No. . . . Cast-iron hay-racks, 3 feet wide and 2 feet high in the clear.  $1\frac{1}{4}$ -inch round staves, about 3 inches apart, the frames  $1\frac{1}{4}$  by  $\frac{3}{4}$  of an inch, with the arris rounded off next the staves. Provide and fix two manger rings in each stall.

*Cast iron coping* to the walls of the dung-pit of the thickness of  $\frac{7}{8}$  of an inch, and returned on each side 4 inches down at the least.

*Cast iron gratings* to stable yards are usually described as of the weight of 1 cwt.

For church and chapel work, the founder's, smith's, and ironmonger's work is so dependent on the design, that no general instructions for specifications can be given.

The following are the only peculiarities : —

Provide *cast iron saddle bars* for the windows  $\frac{3}{4}$  by  $1\frac{1}{4}$  inch, 12 inches longer than the clear width of each window, laid into and worked up with the brickwork, at the height shown on the drawings.

Provide to each window wrought iron framework for a hopper casement, as shown on the drawings, and fit up the same complete, with patent lines, brass pulleys, and all other requisite appurtenances.

**2287. PLASTERER.** To *lath, plaster, float, and set* all the ceilings and strings of stair-cases, and the quartered partitions of the . . . chambers (such as servants' rooms) on attic stories.

To *render, float, and set* all brickwork in attic stories.

To plaster all sides of the kitchen offices and office passages with best floated rough stucco, lathed where requisite.

All the remainder of the sides of the interior throughout is to be executed with the very best floated stucco, lathed where requisite. Stucco of offices (or office buildings if any) to be finished with rough surfaces; all the rest of the stucco to be troweled quite smooth.

All the arched, groined, panelled, and coffered work, and the bands and architraves, to be executed in gauged stuff, in the best and most accurate manner.

To run plaster cornices round the several rooms, lobbies, passages, and other parts of the building, with enrichments thereto accurately modelled according to the drawings (the enrichments, if so wished, to be described as of *papier maché*). A centre flower to each room on the ground and one-pair floor, where marked, securely fixed to the ceiling. These are, on all accounts, better for security in the *papier maché*, as they can be then screwed to the ceiling.

Basement or ground story (or both, as the case may be) is to be run round in all the rooms, lobbies, passages, &c. with *skirtings of Parker's cement*, 10 inches high,  $1\frac{1}{4}$  inch thick, whitened when soft, and finally washed of stone colour.

The plasterer is to execute all necessary beads, quirks, and arrisses. To stucco all internal and external reveals, to dub out where the work may require it, so as to bring out all extra thicknesses and projections, and to counter-lath the work over large timbers and elsewhere, as may be necessary.

The lathing throughout is to be performed with lath-and-half heart of fir laths, free from sap. Enrichments to be carefully trimmed and finished off, and where heavy leaves or embossed work may require it, to be screwed with strong copper screws.

The ceilings on the two principal floors are to be distempered by the painter. All the rest of the ceilings, strings, and mouldings are to be whitened.

The sides of the rooms in the attic or garrett (as the case may be) stories, as well as the lobbies, closets, passages, &c., are to be finished of such stone colour tints as the architect may direct.

Lime-white stables and coach-house walls, larders, sculleries, cellars, including vaulting under sides of floors where open, &c.

When Parker's cement is used for external works, describe as under : —

To stucco in the very best manner with Parker's cement, jointed to imitate masonry, the whole (or part, if such be the case) of the exterior of the building, with columns, pilasters, plinths, entablatures, strings, mouldings, labels, jambs, reveals, chimneys, chimney moulds, decorations, enrichments, and appurtenances of every kind, as shown on the drawings and profiles. Such works to be subject to such further instructions from the architect as he may think proper, and to be roughly coloured as each portion is executed, and finally coloured when the architect shall so direct, with weather-proof colour.

**PLASTERER.**

ing, fixed with Russia tallow, beer grounds, tar, and the other proper ingredients.

Where desired, decorative chimney moulds, of Parker's cement, and of the value of two guineas, to be provided for each flue.

*Pugging.* To fill in upon the sounding boarding between the joists, where so provided, with good lime and hair pugging mortar, laid throughout 1 inch in thickness.

*Roughcasting.* For the mode of describing this, see Plastering, Sect. IX. (2249.)

2288. **PLUMBER.** To lay the *flats and gutters* with milled lead of 8 lbs. to the foot superficial. Where against walls, to be turned up 7 inches; where against slopes, as rafters, to turn up 10 inches. Rolls not to exceed 27 inches apart.

Work *flashings* of milled lead in the walls of 5 lbs. to the foot, and to turn down over gutters and flats. Where flashings adjoin the slopes of a roof, they should be described to be laid stepwise into the brickwork, and of an average width of 12 inches.

*Hips and ridges* to be covered with milled lead 6 lbs. to the foot, and at least 18 inches wide, well secured with lead-headed nails.

Where eaves gutters are used, describe as follows:—

To put round the eaves at the curb plate 4-inch copper (or zinc) guttering, fixed complete with bands and brackets, with copper (or zinc) pipes . . . inches diameter, with neat heads and appropriate shoes to lead into the gutter or drain.

Domes should be covered with lead from 6 to 8 lbs. to the foot superficial, according to their size, and must be well secured with proper seams or rolls thereto.

For coverings of zinc the reader is referred to Sect. VII. Chap. II. (1792, *et seq.*) of this Book, where the thicknesses will be found.

*Tops and sides of dormers* to be covered with 5-lb. milled lead, turned down all round full 8 inches. A flashing of 5-lb. milled lead 30 inches wide, to be fixed over the sill of the dormer door or window, as the case may be.

*Aprons* of 6-lb. milled lead, and 10 inches wide, should be described to sky-lights.

*External mouldings* of wood should be covered with 6-lb. milled lead, to turn up 6 inches, and to have flashings of 4-lb. milled lead let into the brickwork, and to be turned down 5 inches.

To fix . . . *stacks of rain-water pipes* from the gutters to the drains, of (5) inches bore, turned up from milled lead of 8 lbs. to the foot superficial, and securely fixed with ornamental cistern heads as shall be approved by the architect, and 2-inch strong overflow discharging pipes. Similar description for conveying water from a portico.

No pipes but of lead or zinc should be used against stone buildings. Cast iron pipes should only be used to offices.

In London, it is usual to specify that the water should be laid on for the service of the house in the following manner:—

To lay on from the main of the . . . . . Company water with  $\frac{3}{4}$ -inch strong cast lead pipe to the cistern of the upper water-closet, with ball-cock complete. Similarly to lower water-closet and to such other cisterns as are provided, with ball-cocks, &c. complete, and to pay all official fees.

Line the sinks in the scullery and butler's pantry (and other small ones, if any) with 6-lb. milled lead, and fix thereto 2-inch waste pipes, with brass bell traps complete to go into the drains.

Line the kitchen cistern with milled sheet lead, bottom 9 lbs. and sides 6 lbs. to the foot, with all soldering thereto. To provide to the same a  $1\frac{1}{2}$ -inch waste pipe. Line the kitchen sink with lead of 8 lbs. to the foot, to turn well over the woodwork and to have a 2-inch strong waste pipe to lead into the drain, with brass bell grate complete. A  $\frac{3}{4}$ -inch service pipe and brass cock to be provided from the cistern for supplying water to the sink.

*Roses* pierced with holes of sufficient dimensions to be provided of 10-lb. lead to gutters and rain-water cesspools.

*Water closets* to be constructed and fitted up in every respect complete, with blue basin, the very best patent valve apparatus. Soil pipe of 8-lb. lead and  $4\frac{1}{2}$ -inch bore to lead into drain with strong D trap, lead box 10 inches by 7 and 6 inches deep, of milled lead 10 lbs. to the foot. 1-inch supply pipe to the basin, and all other pipes, wires, cranks, handles, and other proper fitments. The cistern is to be lined, bottom with 8-lb. cast lead, and sides with 5-lb. milled lead.  $1\frac{1}{2}$ -inch waste pipe, soldered in below the dip, with washer and waste complete.

*Inferior water closets* to be provided with strong cast iron trapped basin, with water laid on, and in all respects to be fitted complete.

Provide all stink-traps that may be requisite where the pipes communicate with the drains.

**PLUMBER.**

For cold bath, lay on the water with strong  $1\frac{1}{2}$ -inch lead pipe, with brass cock, and fix  $2\frac{1}{2}$ -inch strong lead waste pipe, with brass washer and plug thereto.

If the hot bath be not of marble, describe as follows: —

Provide and fix a hot bath of copper of 16 ounces to the foot superficial, tinned on the inside, and painted in japan to imitate marble as may be directed. Lay on the water thereto, with waste pipe, cock, water plug, and all other proper fittings as for cold bath.

Common pumps are generally described as 3-inch pumps, with neat cast iron cases fixed complete, with proper lead suction pipe to bring sufficient supply of water from well, and all other appurtenances.

To provide and fix (this where the water is not laid on, as in London) a  $3\frac{1}{2}$ -inch lifting engine pump, with brass barrel; and provide from the well . . . feet of  $1\frac{1}{2}$ -inch strong suction pipe. Service pipes as may be necessary to the cisterns, with all cocks and joints that may be necessary.

Provide all copper nails that may be wanted for laying the works.

To provide in the contract . . . cwt. extra of cast sheet lead, including labour and all proper materials as may be wanted and directed by the architect; and if the same or any part thereof should not be used, there shall be a deduction made for the same on making up the accounts, after the rate of . . . per cwt. for such portion thereof as shall not have been used.

2289. **GLAZIER.** To glaze all the windows with the best Newcastle crown glass, or for offices with second Newcastle crown glass.

The whole of the glazing is to be properly bedded, sprigged, and back-puttied, and to be left whole and clean on the works being rendered up as complete.

When plate glass is to be used, the same must be specified, and the architect must direct the manufactory from which it is to be procured.

2290. **PAINTER.** To knot with silver leaf, pumice down and smooth, and otherwise prepare all the wood and other works intended for painting.

To paint four times in oil, with the best oil and colour, all the internal and external wood and iron works, all the stucco, and all other works that are usually painted.

The walls of the principal staircase, lobbies, and entrance hall are to be imitations of marbles, jointed like masonry, as shall be directed, and varnished twice over with best copal.

The doors, shutters, dadoes, skirtings, boxings, architraves, and other dressings on the ground and one-pair floors (and others if required), are to be grained wainscot (or other wood as may be specified), in an artist-like manner, and varnished twice with best copal varnish.

If mouldings of doors and shutters are to be gilt, specify the same.

The ceilings and cornices on ground and one-pair floor to be painted four times in oil, and flatted and picked in such extra colours as may be directed.

To flat extra, of such tints as may be directed, all the rest of the stucco work and wood work on the principal and one-pair floors.

Sashes to be finished on the outside of . . . colour. The plain painting to be of tints of brown, drab, or stone colour as may be directed.

Distemper ceilings (this to be specified if any are so intended), or paint if intended.

2291. **PAPERHANGER.** To prepare and bring to a proper face all the walls and surfaces intended for papering.

To underline with proper paper, and hang with paper of . . . pence per yard, the rooms on the one-pair floor, and to provide and fix gold beads thereto . . . inches wide: borders, if thought proper, to be specified.

To hang with figured paper, value . . . per yard, the rooms (to be described) on the . . . floor, with borders.

The remainder of the rooms are to be hung with paper . . . per yard, with borders. All the patterns are to be approved of by the architect.

2292. **BELLHANGER.** To provide and fix with all necessary wires, pulls, cranks, and every other appendage, bells from the following places: — [Here enumerate the places.]

2293. We now close the general view of a specification (which has been submitted as nothing more than a skeleton for filling up as different cases may require; to make one which would serve all purposes is obviously impossible) by adding the usual form of a contract.

2294. CONDITIONS. That all the works shall be executed in the best and most workmanlike manner, to the satisfaction of [Here add employer's name], or his architect, without reference thereon to any other person. If any alterations should hereafter be made by order of (the employer), or his architect, by varying from the plans or the foregoing specification, either in adding thereto or diminishing therefrom, or otherwise however, such alterations shall not vacate the contract hereby entered into, but the value thereof shall be ascertained by the said architect, and added to or deducted from the sum hereinafter mentioned, as the case may be; nor shall such alterations, either in addition, diminution, or otherwise, supersede the condition for the completion of the whole of the works, but the contractor shall, if such alterations, of whatever sort, require it, increase the number of his workmen, so that the same, as well as the works contained in the above particulars, shall be completely finished, and so delivered up to (the employer), on or before the day of , in the year , on failure whereof the contractor shall forfeit and pay to (the employer), the sum of for every day that the work remains unfinished and undelivered as aforesaid, which sum the said (the employer) shall be allowed to stop as liquidated damages out of any moneys that may be due and owing to the said contractor on account of the works.

If any doubt or doubts should arise during the execution of the works, or at measuring the extras should any occur, or at making out the accounts as to any extras or other works for which the contractor may consider he may have a claim, over and above the sum hereinafter mentioned, the admission and allowance of any such claim or claims shall be judged of, determined, and adjusted solely by the architect to (the employer), without reference in any way to any other person; it being the intention of these conditions that all such works of every kind that may be necessary for completely finishing the works proposed, for the rectification of any failure from whatever cause arising, and the well maintaining, sustaining, and supporting the whole of the works, as well as alterations and additions, should such be made, so that the whole may remain sound and firm, are implied in the foregoing specification, although the same may not therein be specifically expressed, and that on this, as well as all other matters, no reference to any other person than the aforesaid architect is to be allowed or admitted.

If the contractor should neglect or refuse to carry on the works with such dispatch as is thought proper by the architect, it shall be lawful for (the employer) or his architect, and either of them is hereby empowered to employ such other person or persons as (the employer) or his architect, or either of them, may think fit or necessary, to finish and complete the several unfinished works, after having given notice thereof in writing six days before employing such person or persons, such notice to be left either at the contractor's shop, counting-house, or usual place of abode, without effect, and the amount or amounts of the bill or bills of any artificers that may be so employed shall be deducted out of any moneys that may be due and owing to the said contractor, or any part thereof, as the case may be.

It is hereby agreed, this day of , in the year , between (the employer), on the one part, and (the contractor) on the other part, that he, the said (the contractor), for his executors, administrators, and assigns, doth hereby promise and agree to and with the said (the employer), to do and perform all the works of every kind mentioned and contained in the foregoing particulars, and according and subject to the conditions above recited, and according to the plans prepared and referred to, at and for the sum of pounds; and the said (the contractor) doth hereby agree to abide by and be subject to the several clauses, conditions, and penalties hereinbefore mentioned and contained.

In consideration whereof the said (the employer) doth hereby promise and agree to pay to the said (the contractor), on the certificate of the architect, the aforesaid sum of pounds, in separate payments, it being agreed that neither of the said payments, except the last, shall amount to more than two thirds of the value of the work done at the time of such certificate being given.

In witness whereof the said parties have hereunto set their hand, the day and year above written.

Witness, E. F.

A. B. (the employer.)

C. D. (the contractor.)

## SECT. XIV.

## MEASURING AND ESTIMATING.

2295. The practice of measuring is dependent on rules already given under Mensuration, in Sect. VII. Chap. I. of this Book (1212, *et seq.*), in which are described the methods of ascertaining the superficial and solid contents of any figure. The application of them to architecture, in the practice of measuring and estimating the different parts of a building, forms the subject of this section.

2296. For the purposes of measuring, the common instruments are a pair of 5-foot rods, divided into feet, inches, and half inches, and a 2-foot rule divided into inches and eighths and twelfths of inches, beyond which subdivision, measurements are rarely carried in this country.

2297. The mode of what is called squaring dimensions, as usually practised, is given under Section I. Arithmetic &c., in this Book (868, *et seq.*), to which the reader must refer, if not already fully informed on that head. We shall now at once proceed to the general principles on which the measurement and estimation of work in the several artificers' departments are conducted.

2298. DIGGING is performed by the solid yard of twenty-seven cubic feet (that is, 3 feet  $\times$  3 feet  $\times$  3 feet = 27 feet). Where the ground is soft in consistence, and nothing more is necessary beyond cutting with a spade, a man may throw up a cubic yard per hour, or 10 cubic yards in a day; but if of firmer quality, *hacking* becomes necessary, and an additional man will be required to perform the same work; if very strong gravel, more assistance will be required. If, therefore, the wages of a labourer were 2s. 6d. per day, the price of a yard would be 3d. for cutting only, without profit to the contractor; 6d. for cutting and hacking, and 9d. if two hackers be necessary. In sandy ground, where wheeling becomes necessary, three men will remove 30 cubic yards in a day to the distance of 20 yards, two for filling and one for wheeling. But to remove the same quantity in a day to a greater distance, an additional man for every 20 yards will be required.

2299. The method of ascertaining the quantity of excavation will, of course, be obvious; the quantity is the length multiplied into the depth and width. In the cases of trenches merely dug for the reception of walls, which, of course, are sloped to prevent the earth falling in on the excavators, a mean width is to be taken. Thus, suppose an excavation 24 feet long, 4 feet wide at top, and 2 feet at the bottom (average width therefore 3 feet), and 5 feet deep, we have for the quantity of yard  $\frac{24 \times 3 \times 5}{27} = 13.07$  cube yards.

2300. BRICKWORK. In measuring and estimating the value of brickwork, the following points must be remembered. A rod of brickwork is a mass  $16\frac{1}{2}$  feet square; hence the quantity of superficial feet which it contains is  $272\frac{1}{2}$  feet ( $16.5 \times 16.5$ ), but the  $\frac{1}{2}$  of the foot is too trifling to make it worth while to embarrass calculations with it, and consequently 272 feet is universally taken as the superficial standard content of a rod. Its standard thickness is one brick and a half (or  $13\frac{1}{2}$  inches). Hence it follows, that a cubic rod of brickwork would be 272 feet  $\times$   $13\frac{1}{2}$  inches = 306 feet cube. The allowance for the number of bricks is taken on an average at 4500. Much, however, depends on the closeness of the joints and the nature of the work. In walling, a reduced foot is generally taken as requiring 17 bricks; a foot superficial in Flemish bond, laid in malm facing, about 8 bricks; and a foot superficial of gauged arches, 10 bricks. In paving, a yard requires 82 paving bricks, or 48 stock bricks, or 144 Dutch clinkers laid on edge, or 36 bricks laid flat.

2301. In tiling, which is measured by the square of 100 superficial feet, a square will require 800 at a 6-inch gauge, 700 at a 7-inch gauge, and 600 at an 8-inch gauge. The gauge necessarily regulates the distance of the laths, and, at the same time, must be dependent on the slope of the roof, which, if flat, should not be less than 6 inches, as for instance, above the kerb in a kerb roof; and not more than 8 inches in any case. A square of plaiting requires about on an average a bundle of laths, two bushels of lime, and one of sand, and at least a peck of tile pins. The laths are sold in bundles of 3, 4, and 5-foot lengths. A bundle of the 3-feet contains eight score, the 4-feet six score, and the 5-feet five score to the bundle. The nails used are fourpenny; they are purchased by the long hundred, that is, of six score, and, in day work, are charged by the bricklayer 5-score to the hundred. The name of nails, as fourpenny, fivepenny, &c., means fourpence, fivepence, &c. per hundred. The numbers of nails required for a bundle of 5-feet and 6-feet laths, are 500 and 600 respectively.

2302. A square of pantiling requires 180 tiles laid at a 10-inch gauge, and a bundle of 12 laths 10 feet long.

2303. In lime measure, what is called a hundred is 100 pecks, or 25 striked bushels (old measure).

2304. In sand measure, 18 heaped bushels, or 21 struck bushels, equal to 1 yard cube, is a single load, and about 24 cubic feet 1 ton.

2305. In mortar 27 cubic feet make 1 load, which on common occasions contains half a hundred of lime with a proportional quantity of sand. Eleven hundred and thirty-four cubic inches make a hod of mortar; that is, a mass 9 inches wide, 9 inches high, and 14 inches long. Two hods of mortar are nearly equal to half a bushel. The following measures and weights it may be also useful to remember:—

23½ cubic feet of sand = 1 ton; hence 1 cubic foot weighs 95·3 lbs.

17½ cubic feet of clay = 1 ton; hence 1 cubic foot weighs about 130 lbs.

18 cubic feet of common earth = 1 ton; hence 1 cubic foot weighs nearly 124 lbs.

306 cubic feet of brickwork = 13 tons; hence 1 cubic foot is equal to full 95 lbs.

2306. In the measurement of brickwork, from the surface being 272 feet and the standard thickness 1½ brick, it will be immediately seen that nothing more is requisite than, having ascertained the thickness of each part of the work, to reduce it to the standard thickness above stated, and this will be found sufficiently easy in almost all cases. Where, however, this cannot be done, we can always ascertain with sufficient accuracy the cubic contents in feet of any mass of brickwork; and dividing by 306 we have the number of rods.

2307. We here present an illustration in a wall of the most common occurrence (*fig. 808.*), which we will suppose 20 feet long without reference to any wall which might return from it, and thus diminish its length in measuring therewith a *returning wall*. The following is the method of entering and calculating the dimensions.

Fig. 808.

	Length multiplied by the Height.	Area.	Number of Bricks in Thickness.	Factors to reduce the Area to Standard of 1½ Brick.	Thickness reduced to 1½ Brick in Feet sup.
Footings 6 courses	20·0 6	10·0	4	2½	26·8
	20·0 6	10·0	3½	2½	23·4
	20·0 6	10·0	3	2	20·0
	20·0 6·0	120·0	2½	1½	200·0
Basement wall -	20·0 12·0	240·0	2	1½	320·0
Ground-floor wall	20·0 14·0	280·0	1½	1	280·0
One-pair wall -	20·0 7·0	140·0	1	¾	93·4
Two-pair wall -					963·4

Therefore the total is 963·4 superficial feet 1½ brick thick, and  $\frac{963}{272} = 3$  rods, 147 feet.

2308. Upon this principle the measuring and estimation of brickwork is conducted, and having the price and quantity of bricks in a rod, and the lime, sand, and labour, which will presently be given, we may come to a pretty accurate knowledge of its value. But there are other articles which will require our attention, to which we shall presently advert. Before proceeding, however, we may as well observe that the above result of 3 rods 147 feet might have been similarly obtained by cubing the mass of brickwork and dividing the whole mass by 306, but with much more labour.

2309. In measuring walls faced with bricks of a superior quality, the area of such facing must be measured, or allowance extra is made in the price per rod of the brickwork.

2310. All apertures and recesses from any of the faces are deducted.

2311. Guaged arches are sometimes deducted and charged separately, sometimes not; but whether deducted or not does not signify, as the extra price must be allowed in the latter case and the whole price in the former. Rubbed and guaged arches, of whatever form, are measured and charged by the superficial foot.

2312. The angles of groins, outside and inside splays, bird's mouths, bull's noses, are measured by the lineal or running foot; but cuttings are measured by the foot superficial. Chimneys are measured solid to allow for the trouble of forming and pargetting the flues. The opening at bottom, however, is to be deducted.

2313. Quarters in bricknogging are measured in, as are all sills, stone strings, and timber inserted in walls. Two inches are also allowed in the height of brickwork for bedding plates if no brickwork be over them.

2314. Ovens, coppers, &c. are measured as solid work, deducting only the ash holes; but all fire stone, Welsh lumps, tiles, &c., though measured alone, are not to be deducted out of the brickwork. Pointing, colouring, &c. to fronts, is measured by the foot superficial. Plantile creesing by the foot lineal.

To estimate the value of a rod of brickwork, the method is as under:—

4500 stocks, at	per thousand	-	-	-	-	-	£	s.	d.
1½ hundred of lime=37½	striked bushels containing 27 feet cube to the	-	-	-	-	-	0	0	0
hundred	-	-	-	-	-	-	0	0	0
2 loads of sand	-	-	-	-	-	-	0	0	0
Labour and scaffolding	-	-	-	-	-	-	0	0	0
							0	0	0
Per cent. profit	-	-	-	-	-	-	0	0	0
Per rod	-	-	-	-	-	-	0	0	0

2315. In measuring and estimating all sorts of artificers' works, the method usually adopted for saving labour in making out the account is to arrange in separate columns each sort of work, and then to add them up and carry the total to the bill. In brickwork, where walls are of different thicknesses, these with their deductions are arranged in separate columns, and then all are reduced to the standard thickness.

2316. The common measure for tiling is a square of 10 feet, containing therefore 100 feet superficial. Claims are made for the eaves to the extent of 6 inches; but in pantiling this ought not to be allowed, as a claim not founded in justice, though custom is pleaded for it.

2317. The following table shows the number of bricks necessary for constructing any number of superficial feet of walling from 1 to 90,000, and from half a brick to 2½ bricks thick; and thence, by addition only, to any thickness or number required, at the rate of 4500 bricks to a reduced rod. Thus, if it be required to find the number of bricks wanted to build a piece of work containing 756 feet super. of walling 1½ brick thick, we find by inspection for 700 feet 11580 bricks; for 50 feet, 827 bricks; and for 6 feet, 99 bricks; in all, 11580 + 827 + 99 = 12506.

TABLE SHOWING THE REQUISITE QUANTITY OF BRICKS FOR A GIVEN SUPERFICIES OF WALLING.

Area of Wall in Feet.	No. of Bricks to Thicknesses of				
	½ Brick.	1 Brick.	1½ Brick.	2 Bricks.	2½ Bricks.

The use of the foregoing tables it can scarcely be necessary to explain. They are such as to indicate, on inspection, their value; and we shall therefore leave them without further comment for their application.

2322. When work is performed by the day, or the materials used are to be numbered, as oftentimes necessarily occurs, fire bricks, red rubbers, best marle stocks for cutters, second best ditto, pickings, common bricks, place bricks, paving bricks, kiln-burnt bricks, and Dutch clinkers are charged by the thousand.

2323. Red rubbers, kiln and fire-burnt bricks, are also charged by the hundred. Foot tiles and ten inch tiles are charged either by the thousand or hundred.

2324. Sunk foot tiles and ten-inch tiles with five holes, now never used in the south of England, are charged by the piece.

2325. Pantiles, plain tiles, and nine-inch tiles are charged by the thousand.

2326. Oven and Welsh oven tiles, Welsh fire lumps, fire bricks, and chimney pots are also sold by the piece.

2327. Sand, clay, and loam are charged by the load; lime sometimes by the hundred weight; but the *hundred* of 100 pecks is the more usual measure in and about the metropolis. Dutch terras is charged by the bushel, which is also sometimes the measure of lime. Parker's cement is similarly charged.

2328. Pantile and plaintile laths are charged by the bundle or load; hair and mortar by the load; hip hooks and T tiles by the piece.

2329. Neither here, nor in the following pages, is it intended to convey to the reader more than the principles on which an estimate is founded. The prices of materials are in a state of constant fluctuation; and though when we come to the consideration of the prices of joiner's work, we intend, from the ingenious computations of Mr. Peter Nicholson, to give something approaching a constant value from the known performance of a good workman, it is to be recollected by the student, that cases so vary as to make it impossible to give a list of prices and value, that would be of any value at the period of a month from the time of his reading this paragraph. The details of prices he must constantly watch if he intends to do justice to his employer.

#### CARPENTRY AND JOINERY.

2330. The works of the CARPENTER are the preparation of piles, sleepers, and planking, and other large timbers, formerly much, but now rarely, used in foundations; the centering on which vaults are turned; wall plates, lintels, and bond timbers; naked flooring, quarter partitions, roofing, battening to walls, ribbed ceilings for the formation of vaulting coves, and the like in lath and plaster, posts, &c.

2331. In large measures, where the quantity of materials and workmanship is uniform, the articles are usually measured by the square of 100 feet. Piles should be measured by the foot cube, and the driving by the foot run according to the quality of the ground into which they are driven. Sleepers and planking are measured and estimated by the foot, yard, or the square.

2332. Plain centering is measured by the square; but the ribs and boarding, being different qualities of work, should be taken separately. The dimensions are obtained by girting round the arch, and multiplying by the length. Where groins occur, besides the measurement as above, the angles must be measured by the foot run, that is, the ribs and boards are to be measured and valued separately, according to the exact superficial contents of each, and the angles by the linear foot, for the labour in fitting the ribs and boards, and waste of wood.

2333. Wall plates, bond timbers, and lintels are measured by the cubic foot, and go under the denomination of *fir in bond*.

2334. In the measurement and valuation of naked flooring, we may take it either by the square or the cube foot. To form an idea of its value, it is to be observed, that in equal cubic quantities of small and large timbers the latter will have more superficies than the former, whence the saving is not in proportion to the solid contents; and the value, therefore, of the workmanship will not be as the cubic quantity. The trouble of moving timbers increases with their weight, hence a greater expenditure of time; which, though not in an exact ratio with the solid quantity, will not be vastly different, their sections not varying considerably in their dimensions. As the value of the saving upon a cube foot is comparatively small to that of the work performed by the carpenter, the whole cost of labour and materials may be ascertained with sufficient accuracy when the work is uniform.

2335. When girders occur in naked flooring, the uniformity of the work is thereby interrupted by the mortices and tenons which become necessary; thus the amount arising from the cubic quantity of the girders would not be sufficient at the same rate per foot as is put on the other parts, not only because of the difference of the size, but because of the mortices which are cut for the reception of the tenons of the binding joists. Hence, for

valuing the labour and materials, the whole should be measured and valued by the cubic quantity, and an additional rate must be put upon every solid foot of the girders; or, if the binding joists be not inserted in the girders at the usual distances, a fixed price must be put upon every mortice and tenon in proportion to their size. The binding joists are not unfrequently pulley or chase-morticed for the reception of the ceiling joists; sometimes they are notched to receive the bridging joists on them, and they should therefore be classed by themselves at a larger price per foot cube, or at an additional price for the workmanship, beyond common joisting. All these matters must be in proportion to the description of the work, whether the ceiling joists be put in with pulley mortices and tenons, or the bridgings notched or adzed down.

2336. Partitions may be measured and estimated by the cube foot; but the sills, top pieces, and door heads should be measured by themselves, according to their cubic contents, at a larger price; because not only the uniform solidity, but the uniform quantity, of the workmanship is interrupted by them. The braces in trussed partitions are to be taken by the foot cube at a larger price than the common quartering, on account of the trouble of fitting the ends of the uprights upon their upper and lower sides, and of forming the abutments at the ends.

2337. All the timbers of roofing are to be measured by the cubic foot, and classed according to the difficulty of execution, or the waste that occurs in performing the work. Common rafters, as respects labour, are rated much the same as joists or quarters; purlins, which require trouble in fitting, are worth more, because on them are notched down the common rafters. The different parts of a truss should, to come accurately at the true value, be separately taken, and the joggles also separately considered, including the tenons at the ends of the struts; morticing tie beams and principals, forming the tenons of the truss posts, morticing and tenoning the ends of the tie beams and principals, is in another class. The strapping is paid for according to the number of the bolts. Common or bridging rafters' feet are also to be considered; the size and description of the work being always matter for the consideration of the architect.

2338. It is usual and fair to measure the battening of walls by the square, according to the dimensions and distances of the battening.

2339. Ribbed ceilings are taken by the cubic quantity of timber they contain, making due allowance for the waste of stuff, which is often considerable. The price of their labour is to be ordered by the nature of the work, and the cubic quantity they contain.

2340. Trimmers and trimming joists are so priced as to include the mortices and tenons they contain, and also the tenons at the extremities of the trimmers. But to specify all the methods required of ascertaining the value of each species of carpenter's work would be impossible, with any respect to our limits. They must be learned by observation; all we have to do is with the principles on which measuring and estimating is conducted.

2341. When the *carcass* of the building is completed, before laying the floors or lathing the work for receiving the plastering, the timbers should be measured, so that the scantlings may be examined and proved correct, according to the specification; and in this, as a general rule, it is to be remembered that all pieces having tenons are measured to their extremities, and that such timbers as girders and binding joists lie at least 9 inches at their ends into the walls, or  $\frac{1}{3}$  of the wall's thickness, where it exceeds 27 inches. In the measurement of bond timber and wall plates, the laps must be added to the net lengths. If a necessity occur for cutting parallel pieces out of truss posts (such as king or queen-posts), when such pieces exceed 2 feet 6 inches in length, and 2 $\frac{1}{2}$  inches in thickness, they are considered as pieces fit for use, deducting 6 inches as waste from their lengths.

2342. The boarding of a roof is measured by the square, and estimated according to its thickness, and the quantity of boards and the manner in which they are jointed.

2343. Where the measurement is for labour and materials, the best way is, first, to find the cubical contents of a piece of carpentry, and value it by the cubic foot, including the prime cost, carting, sawing, waste, and carpenter's profit, and then to add the price of the labour, properly measured, as if the journeyman were to be paid. It is out of the question to give a notion of any fixed value, because it must necessarily vary, as do materials and labour; hence no tables or price-books are ever to be depended upon; they gull the unwary, and mislead the amateur who consults them. The only true method of forming a proper estimate is dependent on the price of timber and deals, for which general tables may be formed, and some will be presently given.

2344. It is, perhaps, unnecessary to repeat that a load of fir timber contains 50 cube feet: if, then, we know the price of the load in the timber merchant's yard, we may approximate the value of a cube foot as under. We will suppose the price to be, at the moment of estimating, 4*l.* 10*s.* per load. We shall then have —

	£	s.	d.
Prime cost of a load of fir	-	-	4 10 0

2345. Now,  $\frac{6*l.* 18*s.* 6*d.*}{50} = 2.77$  shillings, or 2 shillings and 9 pence and nearly 1 farthing per foot cube.

2346. It is only in this way that we can arrive at the value of work; and it is much to be regretted that from no species of labour of the carpenter have been formed tables capable of furnishing such a set of constants as would, by application to the rate of a journeyman's wages, form factors, or, in other words, furnish data for a perpetual price-book. As we have before hinted, the best of the price-books that have ever been published are useless as guides to the value of work. The method of lumping work by the square is as much as possible to be avoided, unless the surfaces be of a perfectly uniform description of workmanship; as, for instance, in hipped roofs, the principal trouble is at the hips, in fitting the jack rafters, which are fixed at equal distances thereon; hence such a price may be fixed for the cubic quantity of hips and valleys as will pay not only for them, but also for the trouble of cutting and fixing the jack rafters. Such parts, indeed, as these should be separately classified; but the analysis of such a subject requires investigation of enormous labour; and as it must depend on the information derived from the practical carpenter, is, we fear, not likely to be soon, if ever, accomplished.

2347. Mr. Peter Nicholson, a gentleman to whom the architect as well as the practical man are more indebted than to any other author on this subject, is the only person who has attempted to promulgate a system founded on the scientific basis to which we have just alluded; and we have much pleasure in here alluding to the value of his labour, and of placing before the reader the extent to which he carried it, regretting much that he did not further pursue an investigation, which we have carried to a greater extent, though not now so complete as we could have wished.

2348. It is manifest that if the average time of executing each species of work were known, no difficulty could exist in fixing uniform rates of charge for it; but, as we have observed, the parties who could best instruct us on the subject are those most interested in withholding such information as would be required for the purpose. We shall now proceed to the question, premising that, for the present, we are only dealing with the cost of labour, that of the materials being a simple affair, as we have already seen in the case of ascertaining the value of a cubic foot of fir, and as we shall hereafter see in ascertaining the value of superficial feet of deals of any thickness.

2349. In the subjoined tables, the price is represented by the days, or decimal parts of a day, in which one man can perform the quantity of that sort of work, against which such price is affixed. Hence, knowing the rate per day of such man's wages, it forms a factor by which the value of the labour of such quantity of work will be estimated. We begin by centering.

#### Centering.

For plain cylindric vaults, fixed per square	-	-	2.033 days.
For groins of cylindric vaults, fixed per foot super.	-	-	.057
For gauged brickwork, per foot super.	-	-	.073
For brick trimmers bridgewise, per foot super.	-	-	.041
For coach-head trimmers, per foot super.	-	-	.057
For apertures, per foot run	-	-	.02

2350. To apply this to practice, we will take the first article in the table, that of the centering of a cylindric vault, a square whereof, we see, will occupy a man 2.033 days to make and fix. Now, supposing such man's wages to be 5*s.* per diem, we have only to multiply 2.033 by 5*s.* = 10.165, or nearly 10*s.* 2*d.* for a square of such work. The other items being similarly used, will give the results whereof we are in search.

The next table is one composed of several miscellaneous articles, and is as follows:—

Fir in bond and wood bricks, at per foot run	-	-	.008 day.
Fir in templates, lintels, and turning pieces, at per foot run	-	-	.025
Planing fir, from the saw, per foot super.	-	-	.017
Rebating fir up to 2 in. by $\frac{3}{4}$	-	-	.025
Rebating fir from 2 in. by $\frac{3}{4}$ to 3 in. by $\frac{1}{2}$	-	-	.041

Single beading, up to $\frac{3}{4}$ inch	-	-	-	-	-	008 day.
Single quirk beading, from $\frac{3}{4}$ inch to $1\frac{1}{4}$	-	-	-	-	-	012
Return beads, worth double.						

The next table is for quarter partitions : —

Common 4-inch, per square	-	-	-	-	-	1 033 days.
Common 5-inch, per square	-	-	-	-	-	1 113
Common 6-inch, per square	-	-	-	-	-	1 307
Common 6-inch, circular plan, per square	-	-	-	-	-	1 888
Common trussed frame, with king-post, per square	-	-	-	-	-	1 743
Common trussed frame, with king and queen-posts, per square	-	-	-	-	-	2 226

The subjoined is a table for naked flooring : —

Ceiling floor, framed with tie beams, binding and ceiling joists, fixed per square	-	-	-	-	-	1 355 days.
Ceiling floor, with tie beams and ceiling joists only, fixed per square	-	-	-	-	-	1 065
Ceiling joists only, fixed per square	-	-	-	-	-	646
Single-framed floor, trimmed to chimney, and well holes less than 9 inches deep, fixed per square	-	-	-	-	-	1 355
The same, above 9 inches deep, fixed per square	-	-	-	-	-	1 646
The same, if trimmed to party walls, add extra per square, 388.						
Single-framed floor, with one girder, fixed per square	-	-	-	-	-	1 936
Strutting to be paid for extra.						
Single-framed floor-case and tail-bays, fixed per square	-	-	-	-	-	2 130
For every extra bay, add per square, 484.						
Framed floors, with girders, binding and ceiling joists, fixed per square	-	-	-	-	-	3 581
Ground joists, bedded, fixed per square	-	-	-	-	-	775
Ground joists, framed to chimneys, fixed per square	-	-	-	-	-	968
Ground joists, pinned down on plates and framed to chimneys, fixed per square	-	-	-	-	-	1 065
Girders reversed and bolted, per foot run	-	-	-	-	-	097
Truss girder braces, 4 by 4, per foot run	-	-	-	-	-	194

If any of the above works be executed in oak, add one third.

The following table is for roofing of various sorts : —

Common shed roofing, one story high, fixed per square	-	-	-	-	-	968
Common shed roofing, two stories high, fixed per square	-	-	-	-	-	1 033
Common shed roofing, three stories high, fixed per square	-	-	-	-	-	1 113
Single span roofing, one story high, fixed per square	-	-	-	-	-	1 065
Single span roofing, two stories high, fixed per square	-	-	-	-	-	1 113
Single span roofing, three stories high, fixed per square	-	-	-	-	-	1 210
If the above are with purlins, add 194 per square.						
If purlins are framed diagonally, add 388 per square.						

Hips and valleys, per foot run - - - - - 08

In common kerb roofing, add extra per square, when one side is kerbed - - - - - 194

When three sides - - - - - 357

When four sides - - - - - 516

Girt of roofing, with framed principals, collar beams, and purlins, fixed per square - - - - - 2 323

Framed with principals, beams, king-posts, purlins, and common rafters, fixed per square - - - - - 3 484

If the principals and rafters are framed flush, and the purlins housed in, add 387 day to the above.

Framed with principals, beams, king-posts, queen-posts, and common rafters, three stories, fixed per square - - - - - 4 549 days.

The same, four stories, fixed per square - - - - - 4 84

Hips and valleys, per foot run - - - - - 145

Hip and ridge rolls, fixed in iron, per foot run - - - - - 048

Bedded plates to common span roofing, per foot run - - - - - 008

Bedded plates to framed roofing, as above, per foot run - - - - - 028

Diagonal and dragon pieces, per foot run - - - - - 065

Angular ties and struts, per foot run - - - - - 032

Rafters' feet and eaves bond, per foot run - - - - - 032

The table for guttering is as follows : —

Inch or inch and quarter deal and bearers, including 6-inch layer board, per foot super. - - - - - 057

The same in kerb roofs, per foot super. - - - - - 073

For furrings and battennings, table as follows : —

If the stuff be $\frac{3}{4}$ by $1\frac{1}{2}$ inch, fixed per square	-	-	-	·872 day.
If it has also to be cut out, add ·146 per square.				
Battennings with quarters, 3 by 2 inches, fixed per square	-	-	-	·92
Battennings to quarters, 3 by 2 inches to window piers, fixed per square	-	-	-	1·355

If the battens be fixed to plugs, add ·29 per square.

When any of the above are circular on the plan, half as much more must be added to the price of the work.

Table for bracketing, including plugging, is as under : —

To straight cornices, fixed per foot super.	-	-	-	·089 day.
To coved straight cornices, fixed per foot super.	-	-	-	·065
If circular on the plan, add one half more.				
To groins in passages less than 4 feet wide, fixed per foot super.	-	-	-	·162
To the same above 4 feet, fixed per foot super.	-	-	-	·121

2351. The works of the JOINER consist in the preparation of boarding, which is measured and estimated by the foot superficial. Of this there are many varieties; as, edges shot; edges shot, ploughed, and tongued; wrought on one side and edges shot; the same on both sides and edges shot; wrought on both sides and ploughed and tongued. Boards keyed and clamped; mortice clamped, and mortice and mitre clamped. The value per foot increases according to the thickness of the stuff. When longitudinal joints are glued, an addition per foot is made; and if feather-tongued, still more.

2352. The measurement and estimation of floors is by the square, the price varying as the surface is wrought or plain; the method of connecting the longitudinal and heading joints, and also on the thickness of the stuff; as well as on the circumstance of the boards being laid one after another or folded; or whether laid with boards, battens, wainscot, or other wood. Skirtings are measured by the foot super., according to their position, as whether level, raking, or ramping. Also on the manner of finishing them, as whether plain, torus, rebated, scribed to floors or steps, or whether straight or circular on the plan.

2353. The value of every species of framing must depend on the thickness of the stuff employed, whether it is plain or moulded; and if the latter, whether the mouldings be struck on the solid, or laid in; whether mitred or scribed, and upon the number of panels in a given height and breadth, and also on the form of the plan.

2354. Wainscotings, window-linings, as backs and elbows; door linings, such as jambs and soffits; back linings, partitions, doors, shutters, and the like, are all measured and valued by the foot super. The same mode is applied to sashes and their frames, either together or separately.

2355. Skylights, the prices whereof depend on their plans and elevations, are also measured by the foot super. Framed grounds, by the foot run.

2356. The value of dado, which varies as the plan is straight or circular, or being level or inclined, is measured by the foot super.

2357. In the measurement of staircases, the risers, treads, carriages, and brackets are, after being classed together, measured by the foot super., and the string board is sometimes included. The value varies as the steps may be flyers or winders, or from the risers being mitred into the string board, the treads dovetailed for balusters and the nosings returned, or whether the bottom edges of the risers are tongued into the step. The curtail step is valued by itself, and returned nosings are sometimes valued at the piece; and if they are circular on the plan, they are charged at double the price of straight ones. The handrail, whose value depends upon the materials and diameter of the well hole, or whether ramped, swan-necked, level, circular, or wreathed; whether got out of the solid, or in thicknesses glued up together, is measured by the foot run. The scroll is charged by itself, as is the making and fixing each joint screw, and 3 inches of the straight part at each end of the wreath is measured in. The deal balusters, as also the iron ones and the iron columns to curtail, housings to steps and risers, common cut brackets, square and circular on the plan, together with the preparing and fixing, are valued all by the piece. Extra sinking in the rail for iron balusters is valued by the foot run, the price depending on the rail as being straight, circular, wreathed, or ramped. The string board is measured by the foot super., and its value is greater or less as it is moulded, straight, or wreathed, or according to the method in which the wreathed string is constructed by being properly backed upon a cylinder.

2358. The shafts of columns are measured by the foot super., their value depending upon the diameter, or whether it be straight or curved on the side, and upon its being properly glued and blocked. If the columns be fluted, the flutes are taken in linear measure, the price depending on the size of the flutes, whose headings at top and bottom are charged by the piece. Pilasters, straight or curved in the height, are similarly measured, and the price taken by the foot super. In the caps and bases of pilasters, besides the mouldings, the mitres are charged so much each, according to the size.

2359. Mouldings, as in double-face architraves, base and surbase, or straight ones struck by the hand, are valued by the foot super. Base, surbase, and straight mouldings wrought by hand, are generally fixed at the same rate per foot, being something more than double-faced architraves. When the head of an architrave stands in a circular wall, its value is four times that of the perpendicular parts, as well on account of the extra time required to fit it to the circular plan as of the greater difficulty in forming the mitres. So all horizontal mouldings on a circular plan are three or four times the value of those on a straight plan, the trouble being increased as the radius of the circle upon which they are formed diminishes. The housings of mouldings are valued by the piece. The value of mouldings much depends on the number of their quirks, for each whereof the price increases. It will also, of course, depend on the materials of which they are formed, on their running figure, and whether raking or curved.

2360. Among the articles which are to be measured by the lineal foot are beads, fillets, bead or ogee capping, square angle staffs, inch ogees, inch quirk ogee, ovolo and bead, astragals and reeds on doors or shutters, small reeds, each in reeded mouldings, struck by hand up to half an inch, single cornice or architrave, grooved space to let in reeds and grooves. And it must be observed, that in grooving, stops are paid extra; if wrought by hand, still more; and yet more if circular. Besides the foregoing, narrow grounds to skirting, the same rebated or framed to chimneys, are measured by the foot run. Rule joints, cantilevers, trusses, and cut brackets for shelves are charged by the piece.

2361. Water trunks are valued according to their size by the foot run, their hopper heads and shoes being valued by the piece. Moulded weather-caps and joints by the piece. Scaffolding, where extra, must be allowed for. Flooring boards are prepared according to their length, not so much each; the standard width is 9 inches; if they are wider, the rate is increased, each board listing at so much per list. Battens are prepared in the same way, but at a different rate.

2362. The following memoranda are useful in estimating:—

1 hundred (120) 12-feet-3-inch deals, 9 inches wide (each deal containing, therefore, 2 feet 3 inches cube), equal  $5\frac{1}{2}$  loads of timber.

1 hundred (120) 12-feet-2½-inch deals, 9 inches wide (each deal containing, therefore, 1 foot 10 inches cube), equal  $4\frac{1}{4}$  loads of timber.

1 hundred (120) 12-feet-1½-inch deals equal 1 reduced hundred.

1 load of 1½-inch plank, or deals, is 400 feet superficial.

1 load of 2-inch plank, or deals, is 300 feet superficial.

And so on in proportion.

24 loads of 10-feet boards, at a 5-inch guage, will finish one square.

20 loads of 10-feet boards, at a 6-inch guage, will finish one square.

17 loads of 10-feet boards, at a 7-inch guage, will finish one square.

15 loads of 10-feet boards, at an 8-inch guage, will finish one square.

13 loads of 10-feet boards, and 2 ft. 6 in. super., at a 9-inch guage, will finish one square.

12 loads of 10-feet boards, and 2 ft. 6 in. super., at a 10-inch guage, will finish one square.

20 loads of 12-feet boards, at a 5-inch guage, will finish one square.

16 loads of 12-feet boards, at a 6-inch guage, will finish one square.

14 loads of 12-feet boards, at a 7-inch guage, will finish one square.

12 loads of 12-feet boards, and 4 feet super., at an 8-inch guage, will finish one square.

11 loads of 12-feet boards, and 1 foot super., at a 9-inch guage, will finish one square.

10 loads of 12-feet boards, and 1 foot super., at a 10-inch guage, will finish one square.

Battens are 6 inches wide.

Deals are 9 inches wide.

Planks are 11 inches wide.

Feather-edged deals are equal to ¾-inch yellow deals; if white, equal to slit deal.

A reduced deal is 1½ inch thick, 11 inches wide, and 12 feet long.

2363. It may here be useful to advert to the mode of reducing deals to the standard of what is called a reduced deal, which evidently contains 1 ft. 4 in. 6 parts cube, for 12 ft.  $\times$  11 in.  $\times$  1½ in. = 1 : 4 : 46, or in decimals, 12 ft.  $\times$  .91666 ft.  $\times$  .125 ft. = 1.375 cube ft. nearly. Hence the divisor 1.375 will serve as a constant for reducing deals of different lengths and thicknesses. Thus let it be required to find how many reduced deals there are in one 14 feet long, 10 inches wide, and 2½ inches thick. Here 14 ft.  $\times$  .8333 ft. (or 10 in.)  $\times$  .20833 (or 2½ in.) = 2.43042 cube feet, and  $\frac{2.43042}{1.375} = 1.767$  reduced deal.

2364. The table which is now subjoined exhibits the prices of deals and parts thereof calculated from 30% to 95% per hundred, a range of value out of which it can rarely happen that examples will occur, though it has fallen within our own experience during the late war to see the price of deals at a very extraordinary height. This, however, is not likely to happen again.

[illegible]

2365. The above table we cannot suppose will require explanation; but as we wish to be quite explicit, we will merely take one example for illustrating its use, premising, that if deals are at a price between, above, or below that stated in the first column, the rules of arithmetic must be applied for the intermediate prices. Suppose deals, then, to be at 45*l.* per hundred; an inspection of the table shows that the value of  $1\frac{1}{2}$ -inch deal is 8*d.* per foot super., or 6*d.* run; that a 12-foot deal 2 inches thick is worth 6*s.* 8*d.*; and that a foot run of 3-inch deal 11 inches wide, which is the standard width, is worth 9*s.* 8*d.* The preceding table, which is applicable purely to joinery, is all that can be given in general terms as to the prices of work; for that which follows we are again indebted, partly to Mr. Peter Nicholson, and partly to our own industry. The information is not all that could be desired on the subject, nor, as we have before said, can constants of labour be easily obtained for every article in a building; but, as far as they go, they must be considered valuable, though they seem not to have met with the reception they deserved. The value of the labour is given as before, in parts and decimal parts of a man's labour in each description of work per diem, so that the factor to be applied to each is the rate per diem at which the journeyman is engaged. The first table subjoined is one for doors, and in the first article of it, by way of application, suppose the wages of the joiner be 5*s.* 6*d.* per diem, that = 5·5 shillings will be the factor, and the price, therefore, of the labour on a  $1\frac{1}{2}$ -inch door, both sides square, will be  $5\cdot5 \times \cdot06 = \cdot330$  shillings, or nearly 4*d.* per foot, without fitting and hanging. If to this be added the price of the quantity of deal used in it, from the foregoing table, we shall arrive at a result not far from its value. We proceed, then, in giving the constants of doors according to their most common descriptions.

#### DOORS, $1\frac{1}{2}$ INCH THICK.

2-panel, both sides square	-	-	-	-	per foot super.	·06
4-panel, both sides square	-	-	-	-		·07
6-panel, both sides square	-	-	-	-		·08
2-panel, quirk ovolo and bead, and square back	-	-	-	-		·1
4-panel, quirk ovolo and bead, and square back	-	-	-	-		·11
6-panel, quirk ovolo and bead, and square back	-	-	-	-		·12
2-panel, bead and flush front, and square back	-	-	-	-		·1
4-panel, bead and flush front, and square back	-	-	-	-		·11
6-panel, bead and flush front, and square back	-	-	-	-		·12
2-panel, bead and butt front, and square back	-	-	-	-		·09
4-panel, bead and butt front, and square back	-	-	-	-		·1
6-panel, bead and butt front, and square back	-	-	-	-		·11
2-panel, quirk ovolo and bead on both sides	-	-	-	-		·14
4-panel, quirk ovolo and bead on both sides	-	-	-	-		·15
6-panel, quirk ovolo and bead on both sides	-	-	-	-		·16
2-panel, bead and butt on both sides	-	-	-	-		·12
4-panel, bead and butt on both ends	-	-	-	-		·13
6-panel, bead and butt on both ends	-	-	-	-		·14
2-panel, bead and flush on both sides	-	-	-	-		·14
4-panel, bead and flush on both sides	-	-	-	-		·15
6-panel, bead and flush on both sides	-	-	-	-		·16

2366. In applying the above table to other thicknesses, for every additional thickness of one quarter of an inch the rate per foot super. must be increased ·005.

2367. When the panels are raised on one side, ·002 must be added, and double that (·004) when raised on both sides. If an astragal or ovolo is on one of the rising sides, ·003 must be added, and double that (·006) if such occur on both sides. Generally, if the number of panels be given, and the price per foot square on one side, with extra work on the other side, its price is one of the same number of panels, and the same number of panels on both sides minus the rate of the first from that of the last. But adding the difference of the second, we have the rate extra on both sides. Thus the rate is ·06 for  $1\frac{1}{2}$ -inch two-panel door, square on both sides, and for a two-panel door, square on one side, with quirk ovolo and bead upon the other, it is ·1. The difference is ·04, which added to ·1 = ·15 for the rate of  $1\frac{1}{2}$ -inch two-panel door, with ovolo and bead on both sides.

2368. We now turn to another of the items to be considered in measuring and estimating works, that of linings, wherein the difference of labour between square-framed door linings, backs, elbows, soffites, or wainscotings, and door square on both sides, where the panels and thicknesses are alike, arises only from planing the panels and the framing on the other side of the door. If the difference, therefore, per foot, on the rate of a door square on both sides, and one square on one side, with any extra work on the other side, be added to the rate of door-linings, backs, elbows, soffites, or wainscotings framed square, we shall have the rate per foot for door-linings, window-linings, or wainscotings, taking the extra work as above considered. The rails and stiles are taken in the rates as not rebated, and

the framed linings for walls or apertures are supposed as made of stuff one quarter of an inch thinner than the doors. Linings are usually about an inch thick, being stiffened by fixing to the wall; but this depends on the distance of the panel's recess from the framing, and on the depth of the moulding employed.

#### FRAMED INCH LININGS.

1-panel, square as in backs	-	-	-	-	per foot super.	·051
3-panel, square as in backs, and elbows measured together	-	-	-	-	-	·071
4-panel, square as in backs, and elbows and soffites	-	-	-	-	-	·061
3-panel, moulded as in backs, and elbows together	-	-	-	-	-	·087
4-panel ditto and soffites measured together	-	-	-	-	-	·077
3-panel, quirk moulded as in backs, and elbows measured together	-	-	-	-	-	·095
4-panel, quirk moulded as in backs, and soffites measured together	-	-	-	-	-	·085
Semicircular moulded soffites in two panels seven times the straight. For each additional quarter of an inch add ·005 to the foot super.						

N.B. In the above table the backs, elbows, and soffites, though numbered as of 3 and 4 panels, are only of one panel each, the number being collected.

#### INCH AND A QUARTER DOOR-LININGS, ONE PANEL HIGH.

Rebated	-	-	-	-	-	per foot super.	·051
Rebated and beaded	-	-	-	-	-	-	·058
Double rebated, not exceeding 7 inches wide	-	-	-	-	-	-	·067
Double rebated, not exceeding 7 inches wide, and one edge beaded	-	-	-	-	-	-	·071
Double rebated, not exceeding 7 inches wide, and both edges beaded	-	-	-	-	-	-	·075
If the plan be circular, the price increases as the diameter diminishes.							
Semicircular heads straight on the plan are worth five times as much as straight.							

SHUTTERS, two panels in height, either shutters or flaps, inch framed, uncut. If mouldings are described, they are considered as to be laid in, but if stuck on the framing, add ·012 to the rate. Add ·016 to the rate for every extra panel, and ·012 for any extra height, and ·008 if they are quirk moulded.

Square	-	-	-	-	-	per foot super.	·071
Bead butt and square	-	-	-	-	-	-	·1
Bead flush and square	-	-	-	-	-	-	·111
Bead flush and bead butt	-	-	-	-	-	-	·131
Two panels in height, inch and quarter, uncut, adding for extras, as in the heading above.							
Moulded and square	-	-	-	-	-	per foot super.	·1
Moulded bead butt	-	-	-	-	-	-	·111
Moulded bead and flush	-	-	-	-	-	-	·135
Moulded on both sides	-	-	-	-	-	-	·111
Ovolo and bead, or quirk ogee front, and square back	-	-	-	-	-	-	·103
Ovolo and bead, or quirk ogee front, with bead and butt back	-	-	-	-	-	-	·123

#### WAINSCOTING, 1½-inch, two panels high, with square fascia, framed up to ceiling.

Square	-	-	-	-	-	per foot super.	·039
Moulded	-	-	-	-	-	-	·055
Quirk moulded	-	-	-	-	-	-	·063
Bead and butt	-	-	-	-	-	-	·051
Bead and flush	-	-	-	-	-	-	·059
Bead and flush, with three reeds	-	-	-	-	-	-	·075

Should either of these be framed with raised mouldings, add ·008 to the rate, or framed with more, ·006 is to be added for each additional panel in height.

#### WAINSCOTING, 1½-inch dwarf, one panel high, including square skirting.

Square	-	-	-	-	-	per foot super.	·047
Moulded	-	-	-	-	-	-	·063
Quirk moulded	-	-	-	-	-	-	·071
Bead and butt	-	-	-	-	-	-	·059
Bead and flush	-	-	-	-	-	-	·067
Bead and flush, with three reeds	-	-	-	-	-	-	·083

If dwarf wainscoting be framed with two panels in height, add ·016 to the rate, as in full wainscoting. When raked to stairs, ·023 extra, and when with raised mouldings, ·007. All cappings are measured run, and the skirtings of stairs must be taken separately from their wainscoting.

**THREE-QUARTER-INCH OR SLIT DEAL, from the bench.**

Edges shot	-	-	-	-	-	-	per foot super.	·004
Wrought on one side	-	-	-	-	-	-	-	·016
Wrought on one side, grooved, tongued, and beaded	-	-	-	-	-	-	-	·028
Wrought on two sides, and edges shot	-	-	-	-	-	-	-	·028
Wrought on two sides, grooved, tongued, and beaded	-	-	-	-	-	-	-	·04
When joints glued, add per foot ·004.								

**INCH AND QUARTER DEAL.**

Wrought on one side, and edges shot	-	-	-	-	-	-	per foot super.	·02
Wrought on both sides, and edges shot	-	-	-	-	-	-	-	·032
Wrought on one side, and ploughed and tongued	-	-	-	-	-	-	-	·036
Wrought on two sides, ploughed, tongued, and beaded	-	-	-	-	-	-	-	·052
With glued joints, add ·004 to the rate.								

**INCH AND HALF DEAL.**

Edges shot	-	-	-	-	-	-	per foot super.	·008
Ploughed and tongued	-	-	-	-	-	-	-	·024
Wrought on one side, with edges shot	-	-	-	-	-	-	-	·02
Wrought on both sides, with edges shot	-	-	-	-	-	-	-	·036
Wrought on both sides, ploughed and tongued	-	-	-	-	-	-	-	·052
With glued joints, add ·012 to the rate.								

**TWO-INCH DEAL, from the bench.**

Edges shot	-	-	-	-	-	-	per foot super.	·02
Ploughed and tongued	-	-	-	-	-	-	-	·036
Wrought on one side	-	-	-	-	-	-	-	·028
Wrought on both sides	-	-	-	-	-	-	-	·044
Wrought on both sides, ploughed and tongued	-	-	-	-	-	-	-	·056
With glued joints, add ·016 to the rate.								

**TWO-AND-HALF-INCH DEAL, from the bench.**

Edges shot	-	-	-	-	-	-	per foot super.	·028
Ploughed and tongued	-	-	-	-	-	-	-	·048
Wrought on one side	-	-	-	-	-	-	-	·048
Wrought on both sides	-	-	-	-	-	-	-	·063
Wrought on both sides, ploughed and tongued	-	-	-	-	-	-	-	·083
With glued joints, add ·016 to the rate.								

**THREE-INCH DEAL.**

Edges shot	-	-	-	-	-	-	per foot super.	·032
Ploughed and tongued	-	-	-	-	-	-	-	·056
Wrought on one side	-	-	-	-	-	-	-	·056
Wrought on both sides	-	-	-	-	-	-	-	·08
Wrought on both sides, ploughed and tongued	-	-	-	-	-	-	-	·103
With glued joints, add ·016 to the rate.								

**INCH BOARDING, one side planed.**

Ploughed and tongued	-	-	-	-	-	-	per foot super.	·24
Glued joint	-	-	-	-	-	-	-	·03
Clamped	-	-	-	-	-	-	-	·056
Mortice clamped	-	-	-	-	-	-	-	·063
Laid with straight joint in floors	-	-	-	-	-	-	-	·02
Keyed dado	-	-	-	-	-	-	-	·044
Keyed in backs and elbows	-	-	-	-	-	-	-	·056
Wrought on both sides, ploughed and tongued	-	-	-	-	-	-	-	·036
Wrought on both sides, glued joint	-	-	-	-	-	-	-	·04
Groove-clamped flaps to shutters, in one height	-	-	-	-	-	-	-	·053
Clamped flaps to shutters, in two heights	-	-	-	-	-	-	-	·071
Inch mortice, clamped, outside shutters	-	-	-	-	-	-	-	·063
Ledged doors, with plain joint	-	-	-	-	-	-	-	·044
Ledged doors, ploughed, tongued, and beaded	-	-	-	-	-	-	-	·056

**PREPARING FLOORING BOARDS, guaged to a width, and rebated to a thickness not more than 9 inches wide.**

Inch deals, 10 feet long	-	-	-	-	-	-	for each board	·063
Inch deals, 12 feet long	-	-	-	-	-	-	-	·075

## PREPARING FLOORING BOARDS.

Inch deals, 14 feet long	-	-	-	-	- for each board	·087
Inch and quarter deals, 10 feet long	-	-	-	-	-	·071
Inch and quarter deals, 12 feet long	-	-	-	-	-	·083
Inch and quarter deals, 14 feet long	-	-	-	-	-	·1
Inch and quarter battens, 10 feet long	-	-	-	-	-	·044
Inch and quarter battens, 12 feet long	-	-	-	-	-	·056
Inch and quarter battens, 14 feet long	-	-	-	-	-	·075

## MOULDINGS, from the bench.

Double-faced architraves	-	-	-	-	- per foot super.	·111
Base and surbase	-	-	-	-	-	·127
When above 4 inches girt, struck by hand	-	-	-	-	-	·127
In a combination of mouldings, with more than two quirks, add ·016 for each.						

## INCH AND INCH AND QUARTER FRAMED GROUNDS TO DOORS, from the bench.

Both edges square	-	-	-	-	- per foot run	·028
One edge square, and the other rebated and beaded	-	-	-	-	-	·032
Rebated on one edge, and beaded on both edges	-	-	-	-	-	·036
Framed to a circular plan with flat sweeps, the head to be thrice the rate of straight, but the smaller the sweep the greater the rate.						

## RUNNING ARTICLES.

Beads and fillets	-	-	-	-	- per foot run	·004
Bead or ogee capping	-	-	-	-	-	·016
Inch ogee	-	-	-	-	-	·016
Inch quirked ogee, or ovolo and bead	-	-	-	-	-	·023
Square angle staff, rebated	-	-	-	-	-	·028
Angle staff, rebated and beaded	-	-	-	-	-	·048
Single cornice or architrave	-	-	-	-	-	·048
Small reeds in reeded mouldings, stuck by hand to $\frac{1}{2}$ an inch	-	-	-	-	-	·004
Reeds above $\frac{1}{2}$ an inch, stuck by hand, including grooved space	-	-	-	-	-	·008
Grooves in ornamental work	-	-	-	-	-	·004
Narrow ground to skirting	-	-	-	-	-	·011
Narrow ground to skirting, rebated or grooved	-	-	-	-	-	·016
Narrow ground, framed to chimneys	-	-	-	-	-	·032
Double-beaded chair rail	-	-	-	-	-	·023
Plugging is included in the above rates. Such of the articles as are circular on plan, to be double rate.						
Legs, rails, and runners to dressers	-	-	-	-	- per foot run	·055
Rule joints to shutters	-	-	-	-	-	·063

## STAIRS, inch and quarter nailed steps, with carriages.

Flyers	-	-	-	-	- per foot super. fixed	·08
Winders	-	-	-	-	-	·111
Flyers, moulded and glued, with close string board	-	-	-	-	-	·103
Winders, moulded and glued, with close string board	-	-	-	-	-	·135
Moulded planceer under steps	-	-	-	-	-	·04
Housings to flyers	-	-	-	-	- each	·127
Housings to winders	-	-	-	-	-	·2
Common cut brackets to flyers	-	-	-	-	-	·143
Common cut brackets to winders	-	-	-	-	-	·286
Fancy brackets to be paid for extra, according to their value						

HANDRAIL, 2 inches deep and  $2\frac{1}{4}$  inches broad.

Deal, moulded	-	-	-	-	- per foot run fixed	·111
Deal, moulded and ramped	-	-	-	-	-	·495
Deal, moulded, level, circular	-	-	-	-	-	·413
Deal, moulded, wreathed	-	-	-	-	-	1·2
Mahogany, moulded, straight	-	-	-	-	-	·263
Mahogany, moulded, ramped	-	-	-	-	-	·831
Mahogany, moulded, ramped, swan-necked	-	-	-	-	-	·927
Mahogany, moulded, level, circular	-	-	-	-	-	1·08
Mahogany, moulded, wreathed, from 12 in. and above	-	-	-	-	-	1·6
Mahogany, moulded, wreathed, under 12 in.	-	-	-	-	-	1·8
Mahogany, moulded, wreathed, not less than 12 in. opening	-	-	-	-	-	2·3
Mahogany, moulded, wreathed, under 12 in. opening	-	-	-	-	-	3·4

**HANDBAIL.**

Extra sinking to rail, for iron balusters	-	-	-	per foot run fixed	·032
Extra sinking to rail, in ramp or wreath	-	-	-		·1
Mahogany moulded cap, wrought by hand, each	-	-	-		·495
Mahogany moulded cap, turned and mitred, each	-	-	-		·4
Mahogany scroll, each	-	-	-		1·8
Making and fixing each joint with joint screw	-	-	-		·231
Making model and fixing iron balusters	-	-	-		2·095
Making model and fixing iron columns to curtail, each	-	-	-		2·142
Preparing and fixing deal bar balusters, each	-	-	-		·04
Preparing and fixing deal bar balusters, dovetailed to steps	-	-	-		·056
Every half rail is measured two-thirds of a whole one; and all rails are measured 3 inches beyond the springing of every wreath or circular part.					
All cylinders used in rails, glued up in thicknesses, to be paid for extra.					

The following have not been before computed : —

**FRENCH CASEMENT FRAMES.**

Plain solid frames, oak sunk sills, weathered and throated for					
1½ inch French casements, quarters not exceeding 4 by 3	-	-	-	per foot super. fixed	·043
Ditto, for 2-inch French casements, quarters 4 by 4	-	-	-		·057
Deal-cased frames, oak sunk sills, with wainscot stiles and beads, for 2-inch French casements	-	-	-		·086
Circular head, measured square	-	-	-		·258
Circular circular head, curve ¼ inch to a foot	-	-	-		·727
If with mahogany stiles and beads, add on the wainscot	-	-	-		·021
If any of the above are for 2½-inch sashes or casements, add on the deal	-	-	-		·014
If any on the wainscot	-	-	-		·021
If any on the mahogany	-	-	-		·028
Extra grooves or beads, add	-	-	-	per foot run	·014
Circular on plan, flat sweep, once and a half the straight.					
Quirk on plan, double.					

**SASHES AND FRAMES, fitted and hung.**

Deal cased frames, oak sunk sills, 1½-inch ovolo sashes, single hung brass pulleys, best white lines, and iron weights	-	-	-	per foot super.	·086
Ditto, double hung	-	-	-		·100
Ditto, double hung, circular head, measured square	-	-	-		·257
Ditto, circular on plan, flat sweep	-	-	-		·143
Deal cased frames, oak sunk sills, 2-inch ovolo sashes, single hung, brass pulleys, best white lines, and iron weights	-	-	-		·100
Ditto, double hung	-	-	-		·107
Ditto, double hung, circular head, measured square	-	-	-		·272
Ditto, double hung, circular on plan, flat sweep	-	-	-		·157
Circular circular head, ¼ inch to the foot	-	-	-		·770
Deal cased frames, oak sunk sills, wainscot pulley pieces and beads, 1½-inch wainscot astragal sashes, brass axle pulleys, single hung with patent lines	-	-	-		·121
Ditto, double hung	-	-	-		·143
Deal cased frames, oak sunk sills, wainscot pulley pieces and beads, 1½-inch wainscot astragal sashes, brass axle pulleys with patent lines, circular on plan, flat sweep	-	-	-		·172
Circular circular head, ¼ inch to the foot	-	-	-		·866
Deal cased frames, oak sunk sills, wainscot pulley pieces and beads, 2-inch wainscot astragal sashes, brass axle pulleys, double hung with patent lines	-	-	-		·143
Ditto, circular head, measured square	-	-	-		·342
Ditto, circular on plan, flat sweep	-	-	-		·214
Circular circular head, ¼ inch to the foot	-	-	-		·909
Deal cased frames, oak sunk sills, mahogany pulley pieces and beads, 1½-inch Spanish mahogany astragal sashes, brass pulleys and patent lines, single hung	-	-	-		·157
Ditto, double hung	-	-	-		·171
Ditto, circular head, measured square	-	-	-		·371
Ditto, circular on plan, flat sweep	-	-	-		·257
Circular circular head, ¼ inch to the foot	-	-	-		·98
Deal cased frames, oak sunk sills, mahogany pulley pieces and					

## SASHES AND FRAMES.

beads, 2-inch Spanish mahogany astragal sashes, brass pulleys and patent lines	- - - - -	per foot super.	·178
Ditto, circular head, measured square	- - - - -		·399
Ditto, circular on plan, flat sweep	- - - - -		·272
Deal cased frames, oak sunk sills, mahogany pulley pieces and beads, 2½-inch Spanish mahogany astragal sashes, brass axle pulleys and patent lines	- - - - -		·243
Ditto, circular on plan, flat sweep	- - - - -		·315
Circular circular head ¼ inch to the foot	- - - - -		1·123
If Honduras mahogany, deduct from the straight	- - - - -		·029
If Honduras mahogany, deduct from the circular	- - - - -		·043
If lamb's tongue, or other modern modelled bar, add on the astragal	- - - - -		·014

## VENETIAN AND PALLADIAN SASHES AND FRAMES, fitted and hung.

Venetian deal cased frames, oak sunk sills, 1½ inch ovolo sashes, brass pulleys, double hung with best flax line and iron weights, per foot super.	- - - - -		·111
Ditto, with 2-inch sashes	- - - - -		·129
Ditto, circular on plan, flat sweep	- - - - -		·172
Palladian head, measured square	- - - - -		·286
Circular Palladian head, measured square	- - - - -		·866
Venetian deal cased frames, wainscot pulley pieces and beads, 1½-inch wainscot astragal sashes, brass pulleys and patent lines, double hung	- - - - -		·157
Ditto, with 2-inch sashes	- - - - -		·172
Ditto, circular on plan, flat sweep	- - - - -		·200
Ditto, Palladian head, measured square	- - - - -		·342
Circular Palladian head, measured square	- - - - -		·952
If any of the above are in 2½-inch wainscot, add on the 2-inch straight	- - - - -		·014
Ditto, on the circular	- - - - -		·028
Ditto, on the circular circular	- - - - -		·043
If in Spanish mahogany, add on similar article in straight wainscot	- - - - -		·043
Ditto, on the circular	- - - - -		·114
If lamb's tongue, add on the astragal	- - - - -		·007
When any of the above sashes are with a bevelled bar up to the rebate, add on the astragal	- - - - -		·014

## FRENCH CASEMENTS, fitted and hung.

1½-inch deal ovolo	- - - - -	per foot super.	·057
2-inch deal ovolo	- - - - -		·064
2½-inch deal ovolo	- - - - -		·071
1½-inch wainscot	- - - - -		·078
2-inch wainscot	- - - - -		·086
2½-inch wainscot	- - - - -		·100
1½-inch Honduras mahogany	- - - - -		·086
2-inch Honduras mahogany	- - - - -		·100
2½-inch Honduras mahogany	- - - - -		·114
1½-inch Spanish mahogany	- - - - -		·100
2-inch Spanish mahogany	- - - - -		·114
2½-inch Spanish mahogany	- - - - -		·129
If with margin lights, add on the deal	- - - - -		·018
If with margin lights, add on the wainscot	- - - - -		·029
If with margin lights, add on the mahogany	- - - - -		·036
If in two heights, add	- - - - -		·021
If in two heights add, on the wainscot	- - - - -		·029
If in two heights, add on the mahogany	- - - - -		·043
Circular on the plan, flat sweep, once and a half the straight, and exceeding ½ inch to the foot, double.	- - - - -		
If astragal and hollow lamb's tongue, or other modern bar, add -	- - - - -		·014
If with bevelled bars up to the rebate, add on the astragal and hollow	- - - - -		·007
Extra rebated edges, grooves, or beads, in deal	- - - - -	per foot run	·014
Extra rebated edges, grooves, or beads, in wainscot	- - - - -		·021
Extra rebated edges, grooves, or beads, in mahogany	- - - - -		·028

## SKYLIGHTS, fixed.

1½-inch deal ovolo	- - - - -	per foot super.	·043
--------------------	-----------	-----------------	------

**SKYLIGHTS.**

2-inch deal ovolo	-	-	-	-	-	-	per foot super.	·050
2-inch oak ovolo	-	-	-	-	-	-		·071
If astragal and ovolo, add	-	-	-	-	-	-		·007

**DADO.**

$\frac{3}{4}$ -inch deal, keyed	-	-	-	-	-	-	per foot super.	·043
1-inch deal keyed	-	-	-	-	-	-		·050
Raking and scribed to steps, add	-	-	-	-	-	-		·012
If ploughed and tongued, add	-	-	-	-	-	-		·007
If feather-tongued, add	-	-	-	-	-	-		·012
Circular on plan, flat sweep	-	-	-	-	-	-		·143
Circular on plan, quirk sweep	-	-	-	-	-	-		·229
If $1\frac{1}{4}$ -inch deal, add on the straight	-	-	-	-	-	-		·007
If $1\frac{1}{4}$ -inch deal, add on the circular	-	-	-	-	-	-		·014
Narrow dado grounds	-	-	-	-	-	-		·018
Narrow dado grounds, circular flat sweep	-	-	-	-	-	-		·043

2369. We have now enumerated the principal articles of joinery in use. If further information be sought, and the reader have not the means of tracing the value in the way by which the constants already given have been obtained, he may refer to some of the price books, whereof we consider Skyring's to be as well digested as any of those that are annually published.

2370. **SLATER.** The work of the slater is measured and estimated by the square of 100 feet superficial. Of the different sorts of slate, and how much a given quantity of each will cover, we have already spoken in Chap. II. Sect. IX. (1798, *et seq.*) To measure slating, in addition to the nett measure of the work, 6 inches are allowed for all the eaves, and 4 inches by their length for hips; such allowance being made in the first-named case because the slates are there double, and in the latter case for the waste in cutting away the sides of the slates to fit. When rags or imperial slates are used an additional allowance of 9 inches is made for the eaves, because those slates run larger than the other sorts.

2371. **MASON.** Solid works, such as pilasters, cornices, coping, stringings, and other solid works, should be first measured to ascertain the cubic quantity of stone they contain as going from the *banker* to the building; and on this, work, as it may happen to be the plain work, sunk work, moulded or circular work, must be measured in superficial feet and separately valued. It is usual to allow a plain face to each joint, but no more than one should be taken to a 3-feet length. In staircases the flyers should be taken where played on the back, their full length and width by three fifths of the depth of the riser, to allow for waste in getting two of the steps from the same block of stone. The measurement for the winders seems to be most properly conducted by ascertaining the nett cubic contents of them, and then making the allowance for waste. Indeed this is a more proper and satisfactory mode for the flyers. The top of the treads are then taken on the superficies as plain work, and the fronts and ends of the risers as moulded work. In an open staircase, the under side of the flyers is measured as plain work; the under side of the winders as circular plain work; the rebates, cuttings out, pinnings in, &c., as they are found. Cylindrical work, such as of columns, after the cube quantity is ascertained, is measured as equal to plain work twice taken. In Portland dressings to chimneys, wherever edges appear, it is customary to add an inch to the dimensions for extra labour; to marble,  $\frac{3}{4}$  of an inch; or to take the running dimensions of the edges.

2372. Paving slabs and stones under 2 inches thick are taken by superficial measure. Cornices are measured by obtaining their girt, and multiplying by their length for the quantity of moulded work in them.

2373. The following are a few constants of the chief articles of labour in mason's work, applicable, as before mentioned, in the carpenter's and joiner's works.

Plain work	-	-	-	-	-	per foot super.	·166
Plain work, rubbed to face	-	-	-	-	-		·18
Plain work, tooled	-	-	-	-	-		·208
Sunk work	-	-	-	-	-		·222
Moulded work	-	-	-	-	-		·278
Moulded work, stopped	-	-	-	-	-		·333
Gothic moulded work	-	-	-	-	-		·445
Gothic moulded work, stopped	-	-	-	-	-		·528
Gothic moulded work, circular	-	-	-	-	-		·556
Circular plain work	-	-	-	-	-		·264
Circular sunk plain work	-	-	-	-	-		·333
Circular moulded plain work	-	-	-	-	-		·361
Circular, plain moulded work, stopped	-	-	-	-	-		·416

2374. **FOUNDER.** The proper mode of estimating cast iron is by the ton or cwt. Moulds for the castings, when out of the common course, are charged extra. Very often, too, cast iron pipes and gutters are, according to their sizes, charged by the yard. (See 1754, *et seq.*)

2375. **SMITH AND IRONMONGER.** Wrought iron for chimney bars, iron ties, screw bolts, balusters with straps, area gratings, handrails and balusters, hook-and-eye hinges, brackets for shelves, chains for posts, wrought iron columns with caps and bases, fancy iron railing, casements, shutterbars, and the like, are charged by the pound, at various prices, according to the nature of the work. In the ironmonger's department nails and brads are charged by the hundred, though sold by weight, seldom exceeding 900 to the 1000. Screws, which take their names from their length, are charged by the dozen. Cast, and also wrought butts and screws, cast and wrought back flaps, butts and screws, side or **H** hinges, with screws, by the pair. All sorts of bolts with screws, of which the round part of the bolt determines the length, by the inch. **H** hinges and cross garnet hinges, by the pair. Other hinges and screws by the piece. Locks by the piece. Pulleys according to their diameters. On all ironmongery 20 per cent. is charged on the prime cost. (See 2253, *et seq.*)

2376. **PLASTERER.** The work of the plasterer is measured, generally, by the yard. The most usual way of measuring stucco partitions and walls is, to take the height from the upper edge of the ground to half way up the cornice, the extra price of the stucco making good for the deficiency of floated work under it. In ceilings and other work, the surface under the cornice is often taken, because there is no deficiency but in the setting, and that is compensated for by the labour in making good. Cornices are measured by the foot, and estimated according to the quantity of mouldings and enrichments they contain. Where there are more than four angles in a room, each extra one is charged at the price per foot run extra of the cornice. Stucco reveals are charged per foot run, and according to their width of 4 or 9 inches or more. Quirks, arrisses, and beads by the foot run, as are margins to raised panels, small plain mouldings, &c. In the case of enriched cornices and mouldings, and flowers to ceilings, they must be considered with reference to the size and quantity of ornament. For these, the papier maché ornaments, (see 2251.) which are much lighter, are coming now into very general use, and from the ease and security with which they are fixed, will, we have no doubt, within no very distant period, supersede all use of plaster ornaments. In subsection 2248 will be found some information useful in the investigation of the value of plasterers' work, and which might form the basis for a set of constants under that head. But we have not been able to obtain sufficient data for carrying them completely out; which, from the minor importance of this branch of building, is perhaps of no very great consequence.

2377. **PLUMBER.** The work of this artificer is charged by the cwt., to which is added the labour of laying the lead. Water pipes, rain-water pipes, and funnel pipes are charged by the foot, according to their diameter; so also are socket pipes for sinks, joints being separately paid for. Common lead pumps, with iron work, including bucket, sucker, &c., at so much each; the same with hydraulic and other pumps, according to their diameters. In the same manner are charged water-closets, basins, air traps, washers and plugs, spindle valves, stop-cocks, ball-cocks, &c. (See 2212, *et seq.*)

2378. **GLAZIER.** The work of the glazier is measured and estimated by the superficial foot, according to the quality of the glass used; it is always measured between the rebates. (See 2225, *et seq.*)

2379. **PAINTER.** In the measurement and estimation of painting, the superficial quantity is taken, allowing all edges, sinkings, and girths as they appear. When work is cut in on both edges it is taken by the foot run. The quantity of feet is reduced to yards, by which painting is charged for large quantities. In taking iron railing the two sides are measured as flat work; but if it be full of ornament, once and a half, or twice, is taken for each side. Sash frames are taken each, and sash squares by the dozen. On gilding we have already spoken in Sect. XII. (2267, *et seq.*) Cornices, reveals to windows and doors, strings, window sills, water trunks and gutters, handrails, newels, &c., are taken by the foot run. Many small articles by the piece. Plain and enriched cornices by the foot run, according to the quantity of work in them. Work done from a ladder is paid for extra. The price depends on the number of times over that the work is painted; and the labour is usually considered as one third of the price charged. Imitations of woods and marbles are also charged extra.

2380. **PAPERHANGER.** In common papers the price varies according to the colours or quantity of blocks used in printing it. Embossed and other papers are of higher prices. These, as well as lining paper, are charged by the piece, containing 63 feet super. The hanging is charged separate, and borders, mouldings, &c. by the yard run. (See 2278.)

## CHAP. IV.

### MEDIUM OF EXPRESSION.

#### SECT. I.

##### DRAWING IN GENERAL.

2381. UNDER this section it is not our intention to enter into the refinements of the art, but merely to make the attempt of directing the student to the first principles of a faithful representation of ordinary and familiar objects, with all their imperfections; or, in other words, of transferring to a plane surface what the artist actually sees or conceives in his mind. This power is of vital importance to the architect, and without it he is unworthy the name. The practice, in these days, of employing draughtsmen to make drawings for competitions, is not less disgraceful to those who have recourse to such a practice, than to the committees and other bodies, who are, in nine cases out of ten, grievously misled and deceived by the practice. Every work in a competition should be strictly limited to lines in its representation, and without colour or shadow. It is not very long since that, in a great competition, we saw drawings shadowed in a way that must have had some other luminary than the sun to light them, unless he had changed for the moment the usual course in which he travels through the heavens, for the gratification of the luminous draughtsman who craved his special aid. We regret that architects generally do not throw aside the pernicious system. There are some few who have done so, and are indebted to the practice for the rank they hold. We shall here merely add, before entering on the subject, that in our opinion, the greatest curse that in these days has fallen on architecture, is the employment of draughtsmen, who with their trumpery colouring and violent effects mislead the silly men and common-place critics that usually decide upon the merits of their works. In the days of Jones, Wren, and Vanbrugh, this was fortunately not the case. We ourselves possess more than one drawing of Wren, which fully prove that the medium of expression for the workman in our own art was then simple, and wanted not such silly aids as those whereof we have been speaking. If proof be required, let the authorities, who ought better to direct these matters, make a pilgrimage to Oxford, and there examine the drawings of Wren, whose equal we cannot point to in the present age. Let them examine the way in which Inigo Jones went to work from the MS. notes on his copy of Palladio, now at Worcester College, and we may hope to see better days. The present mode is that of making a pretty picture; and he who makes the prettiest, provided he have a reasonable number of friends in a committee, is the lucky candidate. But we are wandering from the subject, and must return to that which heads the section.

2382. The usual mode of teaching drawing now in use is, as we conceive, among the most absurd and extravagant methods of imparting instruction that can be well conceived. The learner is usually first put to copying drawings or prints, on which he is occupied for a considerable time. How much more would he learn, and how much more quickly, by drawing at once from the figure or its parts; thus at once, for that the thing is quite possible, we know from experience, acquiring the power of transferring to a plane surface the representation of that which is placed before his eye? And here we deem it proper to apprise the reader that the representation of *form* is all that the architect requires. The power of doing this is no slight acquirement. Under perspective, we shall see in the following section, that for all geometrical solids the representation is dependent on mechanical means, of which every one may easily possess himself; and these may, if it be desirable, be shadowed truly by the methods given in Section III.; but the undulating form of the figure, and the infinite variety of a landscape, by changing the situation of the spectator, is more the matter now to be considered. As to the materials to be used for the purpose, a black lead pencil and some Indian ink or sepia are all that the architect can want. On them we shall not therefore stop to waste his and our own time. It is the practice of going further that has excited the observations with which we began.

2383. We are fully aware of the impossibility by writing merely, without the aid of a master at the student's back, to teach any one the art of drawing. Much, nevertheless, may be imparted, namely, the mechanical means, assisted by a general knowledge of perspective, to place the different parts of a figure or landscape not so violently out of their proper places in the representation as to offend the eye. Here let us mention that our impression is, and we do not believe that any artist will venture to contradict it, that he

who can draw the figure will be able to draw any other object or objects that are submitted to him for representation. Besides this, the freedom he will obtain in the use of his pencil by first employing it in this way, will impart a facility which is by no other means to be attained. This was one of the great powers possessed by the artists of Italy; this made them painters, sculptors, and architects, combining the three arts in one person, and this, lost, has separated the three arts, and the want of it reduced our Academy, with a few exceptions, to parties of whom, with all our best feelings towards them, it cannot be said they are those upon whom the mantle has fallen to do the like. Portrait painting, good enough of itself, has banished real art. This, however, is not the fault of the Academy, but of the selfish feeling of the nation.

2384. We have also, before entering on the few principles to be given, to premise that though for the painter and sculptor a knowledge of anatomy is absolutely requisite, we do not insist upon that for our purpose. It is only to be so far known as to remember that the carpentry of man is his skeleton, and the muscles and integuments the lath and plaster put on the framing. We mean, in fact, that a general knowledge of it for drawing is well to be possessed.

2385. The method proposed in the following pages is as old, at least in principle, as the time at which we ourselves began to learn the art; and we are therefore surprised that it should have been lately published as new in Paris, by M. Dupuis. (*"De l'Enseignement du Dessin sous le point de vue industriel,"* 1836.) The principles of the work, however, are perhaps better expressed and arranged, in some respects, than we might have presented them to the reader: and we shall not, therefore, apologise to our readers for the free use we intend to make of it, premising, however, that we do not in any way admit its novelty, and that, in respect to the whole figure and the application of the method to landscapes, what follows is not found in the work of M. Dupuis.

2386. Outline is the foundation of all drawing, the elementary alphabet of graphic art. Every representation of an object, or series of objects, however complicated, is, in reality, but a set of outlines modified by right and curved lines. The knowledge of these lines, and of their several properties, will greatly abridge the labour of the student, inasmuch as the power, if we may so express ourselves, of reading and writing them by calculating the relations of size and distance which exist between their parts, is, in fact, the faculty of drawing. The elements of perspective may be previously so far entered upon as to acquire facility in drawing in every position, without the aid of those rules which are given in Sect. II.; the cube, cylinder, sphere, pyramid, and other solid bodies, upon which, from the objects themselves actually before him, the student may begin to work. Having acquired freedom and power of accurate representation in this respect, and also a dexterity in the use of his pencil generally, he may commence his operations on the figure itself.

2387. Between the ancient mode of teaching the student (we will take the head, for instance, shown in *fig. 809.* as the first roughing of the leading lines of that which in *fig. 812.* has reached its completion) and the method practised by M. Dupuis, the only difference is this, that M. D., instead of letting the student form the rough outline at once from the finished bust, roughing out on paper the principal masses, provides a series of models roughly bossed out in their different stages, which he makes the student draw. The system is ingenious; but as the greatest artists have been made without the modification in question, we do not think it material; at all events, the principles are the same. M. Dupuis, for this purpose, has a series of sixteen models, the first of each four of the series are quite sufficient to show the old as well as his own practice. Thus, in *fig. 809.*, the general mass of the oval of the head is given, in which it is seen that the profile is indicated by an obtuse angle, whose extreme point corresponds with the lower part of the nose, and the lines at one extremity terminate with the roots or commencement of the hair, and at the other with the lower jaw. The form of the rest of the head is the result of combining the most projecting points of it by curved lines, in short, of supposing a rough mass, out of which the sculptor might actually, in marble or other material, form the head.

FIG. 809.

FIG. 810.

2388. The next step is exhibited in *fig. 810.*, with the four principal divisions: the occipital to the beginning of the hair, the forehead to the line of the eyes, the projection of the nose, and the inferior part of the face, with some indication of the mouth.

2389. In *fig. 811.* it will be seen that another step is gained. The eyes (here only one appears, but we speak with reference to the subject, being less in profile), the mouth, the

chin, and the ear are more clearly marked out, with some sort of expression of the whole work, but still without details, though sufficiently indicating that little more is necessary to bring the rude sketch of *fig. 809.* to a resemblance.

2390. In *fig. 812.* this is obtained; but still, according to the degree to which an artist considers finishing necessary, to be further pursued and carried through to make a perfect drawing; all that is here intended being to show the principles upon which the matter is conducted, and upon which we shall presently have further observations to make. It will be observed that on the shadowing and finishing in this way; the drawings the student may make we set no value: when he can draw, if those matters be of importance to him, they will not be difficult of acquisition. We scarcely think it here necessary to repeat that, having accomplished the art of drawing with tolerable correctness the figure, the architect will have few difficulties to contend with in drawing the most complex and elaborate ornaments employed in architecture. The principles are precisely the same; but we wish here to impress upon him the necessity of recurring to nature herself for his ornaments: a practice which will always impart a freshness and novelty to them which even imitation of the antique will not impart.

2391. The port crayon, whether carrying chalk or a black lead pencil of moderate weight and size, say full seven inches long, is the best instrument to put into the hands of the beginner. The first object he must consider in roughing the subject, as in *fig. 809.*, is the relation the height of the whole bears to its width; and this determined, he must proceed to get the general contour, without regard to any internal divisions, and thus proceed by subdivisions, bearing the relative proportions to each other of the model, comparing them with one another and with the whole. We will now show how the port crayon assists in this operation. Let the pupil be supposed seated before the model, at such a distance from it that at a single look, without changing the position of his head upwards, downwards, or sideways, his eye takes in the whole of it. The strictest attention to this point is necessary, for difficulties immediately present themselves if he is too near, as well as if he is too far from it. And here let it be observed that the visual rays (see *fig. 813.*) upon every object

Fig. 811.

Fig. 812.

Fig. 813.

may be compared to the legs of a pair of compasses, which open wider as we approach the object and close as we recede from it. This is a law of perspective well known, and which the student may easily prove by experiment, keeping the head of the compasses near his eye, and opening the legs to take in, in looking along them, any dimension of an object. He will soon find that as he approaches such object he must open the legs wider in order to comprise within them the given dimension. Hence every diameter or dimension, separately considered, is comprised in the divergence of the visual rays. It is on this account that, being at a proper distance, any moveable measure which with a free motion of his body he can interpose upon some one of the points of the distance between his eye and the model, may, though much less than the model itself, take in the whole field of view, reach the extremities of the dimension, and consequently become of great assistance in certain mathematical measures. For by applying such a measure to one division only of the model, we shall obtain, as it were, an integer for finding a great many others into which the model may be subdivided.

2392. Thus, taking *fig. 809.*, which is profile, and supposing the width at the neck unity, if this is twice and a half contained in the general height of the bust, we have immediately the proportions of one to two and a half, which may be immediately set out on the paper or canvas. This is not all; the integer or unity obtained by the diameter of the

neck serves also for measuring the horizontal diameter of the head, and also of the bust ; whence new proportions may be obtained. So much for the first casting of the general form. Now, in the entire bust, as respects the head only, suppose we wish to obtain the proportions of the principal divisions, — for example, from the base of the bust to the base of the chin, — we may establish another integer to measure other parts ; as, if from the point of view, the distance from the base of the bust to the base of the chin is the same as from the last to the summit of the head, the learner would have nothing more to do in that respect than to divide the whole height into two equal parts. On the same principle, passing from divisions to subdivisions, the distance between the base of the chin and the point whence the nose begins to project, may be found a measure for the height of the nose, and from thence to the top of the cranium. We are here merely showing the method of obtaining different integers for measuring the different parts mentioned ; others will in practice occur continually, after a very little practice. We do not suppose our readers will believe that we propose to teach drawing by mathematical rules ; we now only speak of obtaining points from which undulating and varying lines are to spring and return, and which none but a fine and sensitive eye will be able to express. But to return to the port crayon, which is the moveable measure or compasses whereto we have alluded, and requires only skilful handling to perform the offices of compasses, square, plumb rule, and level. By interposing it (see *fig. 813.*) on the divergence of the visual rays between the eye and the object, we may estimate the relative proportions ; since in the field of view the learner may apply it to the whole or any of the parts, and make any one a measure for another. For this purpose he must hold it, as shown in the figure, steadily and at arm's length. Any portion of it that is cut by the visual rays between any two parts of the object, becomes the integer for the measurement of other parts whereof we have been speaking. This in the drawing will be increased according as the size is greater or less than the portion of the port crayon intercepting the visual rays. This process may be easily accomplished by making, upon one and the same line of the visual ray, the extreme point of the port crayon to touch one of the extremities of the proportion sought upon the model, so that they may exactly correspond. Then at the same time fixing the thumb or fore-finger where the visual ray from the other extremity is intercepted, we shall find any equal length by moving the port crayon with the thumb and fore-finger fixed to any other part we want, as to size, to compare with the first, or by using the same expedient to other parts, other integers may be found. The different integers, indeed, which may be thus obtained is infinite. The port crayon will also serve the purpose of a plumb bob by laying hold of it by the chalk, and holding it just only so tight between the fingers as to prevent its falling, so that its own gravity makes it assume a vertical direction. Doing so, if it then be held up to intercept the visual rays, we may discover the proportion in which a line swells whose direction approaches the vertical, as also the quantity one part projects before another in the model ; and comparing this again with the integer, obtain new points for starting from. Again, by holding it before the eye in an horizontal direction, we shall obtain the different parts of the model that lie before the eye in the same horizontal line. By degrees we shall thus soon find the eye become familiarised with the model it contemplates ; judgment in arranging the parts supervenes ; the hand becomes bold and unhesitating, and the leading forms are quickly transferred to the paper or canvas to be subdivided to such extent as is required by the degree of finish intended to be bestowed upon the drawing.

2393. The process that we have considered more with relation to the bust is equally applicable to the whole figure. In *fig. 814.* we have more particularly shown by the dotted lines the horizontal and vertical use of the port crayon ; but the previous adjustment of some measure of unity for proportioning the great divisions to each other is also applied to it as already stated. In the figure, EE is the line of the horizon, or that level with the eye ; it will be

FIG. 814.

seen passing through the knee of that leg upon which the principal weight of the body is thrown.

2394. Though our object in this section is to give only a notion of the way of transferring to paper or canvas such objects as present themselves, we think it proper to hint at a few general matters which the student will do well to consider, and these relate to the balance and motion of the human figure. Geometry and arithmetic were with the painters of antiquity of such importance that Pamphilus the master of Apelles declared, without them art could not be perfected. Vitruvius particularly tells us the same thing, and, as follows, gives the proportions of the human figure: — "From the chin to the top of the forehead, or to the roots of the hair, is a tenth part of the height of the whole body; from the chin to the crown of the head is an eighth part of the whole height; and from the nape of the neck to the crown of the head, the same. From the upper part of the breast to the roots of the hair, a sixth; to the crown of the head, a fourth. A third part of the height of the face is equal to that from the chin to the under side of the nostrils, and thence to the middle of the eyebrows the same: from the last to the roots of the hair, where the forehead ends, the remaining third part. The length of the foot is a sixth part of the height of the body; the fore-arm, a fourth part; the width of the breast a fourth part. Similarly," continues our author, "have the other members their due proportions, by attention to which the ancient painters and sculptors obtained so much reputation. Just so, the parts of temples should correspond with each other and with the whole. The navel is naturally placed in the centre of the human body; and if a man lie with his face upwards, and his hands and feet extended, and from his navel as the centre, a circle be described, it will touch his fingers and toes. It is not alone by a circle that the human body is thus circumscribed, as may be seen (*fig. 815.*) by placing it within a square. For, measuring from the feet to the crown of the head, and then across the arms fully extended, we find the latter measure equal to the former; so that the lines at right angles to each other, enclosing the figure, will form a square."

Fig. 815.

2395. "How well," says Flaxman (*Lectures on Sculpture*), "the ancients understood the balance of the figure, is proved by the two books of Archimedes on that subject; besides, it is impossible to see the numerous figures, springing, jumping, dancing, and falling, in the Herculean paintings, on the painted vases, and the antique basso-relievos, without being assured that the painters and sculptors must have employed geometrical figures to determine the degrees of curvature in the body, and angular or rectilinear extent of the limbs, and to fix the centre of gravity." Leonardo da Vinci has illustrated the subject in his *Trattato di Pittura*, a perusal of which cannot fail of being highly beneficial to the student.

2396. As in all other bodies, the centre of gravity of the human figure is that point from which, if suspended, the figure would remain at rest when turned round upon it. Flaxman, by some strange mistake, has described the centre of gravity as "an imaginary straight line, which falls from the gullet between the ankles to the ground, when it (the figure) is perfectly upright, equally poised on both feet, with the hands hanging down on each side." (*Fig. 816.*) The fact is, that the centre of gravity is found to be in a line so drawn, or rather removed backwards from it, in a vertical plane returning from that line.

Fig. 816.

Fig. 817.

2397. Motion implies change of position; for instance, in *fig. 817.*, the weight of the figure is thrown on one leg, hence a line passing through the centre of gravity falls from the gullet on one leg, on which side also the shoulder becomes lowered, and that on the opposite side raised; the hip and knee sinking below those on the side supporting the weight. In *fig. 818.* the dotted lines terminated by the letters ABCD represent lines of motion, as also the extent of such motion. The same are also shown in *fig. 819.*, wherein A shows the inclination of the head to the breast; B the extreme bend of the back over the legs, without changing their position; C that of the back bent backwards, the legs

remaining in the same position. If the back be bent as far as D, the thighs and legs will project as far as E.

2398. Referring back to *fig. 817.* for comparison, as the commencement of motion, with *fig. 820.*, we shall immediately see that the preparation for running consists in throwing the balance beyond the standing foot; and that when the centre of gravity, which is now about to take place, falls out of the common base, the hinder leg must be out, and off the ground, to balance the fore part of the figure, which would otherwise fall.

2399. In preparing to strike (*fig. 821.*), the figure is thrown back at the beginning of

Fig. 818.

Fig. 819.

Fig. 820.

Fig. 821.

the action to give force to the blow: the dotted line shows the extent of the springing forward, in which the action is ended by the fall of the blow upon the object.

2400. In *fig. 822.*, bearing a weight, the combined centres of gravity of the figure and

Fig. 822.

Fig. 823.

Fig. 824.

the weight to be borne must be found; and through it the line falls between the feet, if the whole weight rests equally on both, or on the supporting foot, if the weight is thrown upon one. Flaxman, who was a finer artist than a geometrician, has, in his lectures, fallen into another mistake on this head, by saying the centre of gravity is the centre of the incumbent weight, which is absurd; because the figure has not only to balance the weight itself, but also its own weight.

2401. In leaping (*fig. 823.*), the body and thighs are drawn together to prepare for the spring; the muscles of the leg draw up the heel, and the figure rests on the ball of the foot; the arms are thrown back to be ready immediately for swinging forward, and thus assisting in the impulse. When the figure alights, the arms, at the instant of alighting, will be found raised above the head; and a line dropped from the centre of gravity will be found to fall near the heels.

2402. In leaning (*fig. 824.*), if on more than one point, the greatest weight is about that point on which the figure chiefly rests.

2403. *Fig. 825.* is a flying, and *fig. 826.* a falling figure, both whereof being in motion through the air rest on no point. In the first it will be observed that the heaviest portion of the figure is bounded by lines inclined upwards; as in falling the heaviest portion of it has a downward direction. We have thought these elements would be useful, as exhibiting those leading principles without the comprehension whereof no motion or action can be well expressed. "Every change," says Flaxman, "of position or action in the human figure will present the diligent student with some new application of principles, and some valuable example for his imitation."

2404. We shall close this section with the application of the principles detailed in the management of the port crayon to the drawing of landscapes. The subject of *figs. 827.*

Fig. 825.

Fig. 826.

Fig. 827.

Fig. 828.

and 828. is from a spot a little way out of Rome, the tower of Cæcilia Metella being seen in the distance.

2404a. In *fig. 826*, the masses are roughed in from the objects themselves; and the principal mass *abcd* on the left side is first very carefully drawn by itself, being, as respects leading lines and thicknesses, corrected until the eye is satisfied of the truth of its general form. The eye is as high as *E* and *E*, which therefore show the height of the horizontal line, and are also, in fact, the vanishing points for the wall on the right-hand side of the picture, and the house on the same side a little beyond it. Holding the port crayon level, and taking on it with the thumb or forefinger the distance *Ol*, we shall find that twice that measure in 2 and 3 will give the junction of the wall with the pier; and that a line continued horizontally from 2 to the top of the pier will be the pier itself. The picture appears to be divided into two equal parts by a vertical line drawn through *l*, breaking the pier with the distance. *dl*, continued upwards, determines the position of the house on the right side, and *cl* downwards, indicates a point at a break in the foreground between the pier and the wall, and a point at which the pier is broken. The remaining part of the picture, it will be seen, is a simple matter of construction, and thus it is manifest that the whole arrangement has been accomplished by making the mass *abcd* a measure or unit for ascertaining the size and relative position of the other parts. In *fig. 828*, the detail is filled in, and brought to a higher state of finish.

2404b. There is a mechanical method of obtaining the exact relative sizes of objects, and their positions in making drawings from nature or casts, which we will endeavour to explain. If the draftsman take a pair of pretty large sized compasses and, before he has done with the point end of them, hold the points open before his eye, so as to see the object he is to draw, and then, without moving the compasses, turn them round, and the points will be at the same distance from the eye as the object was when they were first opened. The object being now at the same distance from the eye as the compasses, the lines drawn from the eye to the corners of the object, and the lines drawn from the eye to the corners of the compasses, will be parallel, and the object will be drawn to the same scale as the compasses, and thus it is manifest that the whole arrangement has been accomplished by making the mass *abcd* a measure or unit for ascertaining the size and relative position of the other parts. In *fig. 828*, the detail is filled in, and brought to a higher state of finish.

## SECT. II.

### PERSPECTIVE.

2405. A perspective delineation is the linear representation of any object or objects, as it or they appear to the eye, and is such a figure of an object as may be supposed to be made by a plane making a section of the body or pyramid of visual rays directed from the eye to the different parts of the object. A delineation so made, being properly coloured and shadowed, will convey a lively idea of the real object, and at the same time indicate its position and distance from the eye of the observer.

2406. DEFINITIONS. — 1. An *original object* or *objects* is or are an object or number of objects proposed to be delineated: for instance, a house, a ship, a man, or all or any of them together. In *fig. 829*, the house *ABCD FHK* is the original object.

Fig. 829.

2. *Original lines* are any lines that are the boundaries of original objects, or of planes in those objects. The lines *AB*, *BC*, *CD* are original lines, being partly the boundaries of the original object *ABCD FHK*.
3. The *ground plane* is that upon which the objects to be drawn are placed, and is

- always considered a boundless level plane. The plane X in the figure is the ground plane, upon which is placed the object ABCDFHK.
4. *The point of view or point of sight* is the fixed place of the eye of the observer, viewing the object or objects to be delineated : E in the figure is such point.
  5. *The station point* is a point on the ground plane, perpendicularly under the point of sight or eye of the observer, and expresses on the plan the station whence the view is taken. S is the station point in the figure, being a point on the ground plane vertically under the eye of the observer at E.
  6. *The plane of delineation or the picture* is the canvas or paper whereon it is intended to draw any object or number of objects. Thus, in the figure, the plane GIKL is the plane of delineation ; but, in the extensive sense of the word, the plane of delineation is considered a boundless plane, however circumscribed may be the delineation made thereon.
  7. *The horizontal line or the horizon* is a line on the plane of delineation in every part level with the eye of the observer or point of view. VZ is the horizontal line on the plane of delineation GIKL. It is supposed to be obtained by the intersection of a plane passing through the eye of the observer, parallel to the ground plane, produced till it touches the plane of delineation.
  8. *The centre of the picture* is a point perpendicularly opposite the eye of the observer, or point of view, and is consequently always somewhere in the horizontal line. O in the horizontal line VZ is the centre of the picture, being perpendicularly opposite to the eye at E.
  9. *The vertical line* is a line drawn through the centre of the picture perpendicular to the horizon. In the figure PR is the vertical line. It is here worthy of notice that the vertical line determines how much of the view lies to the right and how much to the left of the eye of the artist.
  10. *The distance of the picture* is a direct line from the eye to the centre of the picture. EO is the distance of the picture, or plane of delineation, GIKL.
  11. *The ground line* is that where the ground plane intersects the plane of delineation, as GL in the figure.
  12. *An intersecting point* is one made on the plane of delineation, by producing a line in an original object till it touches the plane of delineation. Thus, T is the intersecting point of the original line BA.
  13. *An intersecting line* is one made on the plane of delineation, by producing any plane in an original object till it touches the plane of delineation, or where, if produced, it would touch it. Thus WT is the intersecting line of the original plane ABCDN, being the line, where that plane, if produced, would touch the plane of delineation.
  14. *A vanishing point* is that point on the plane of delineation to which two or more lines will converge, when they are the perspective representations of two or more parallel lines in an original object, whose seat is inclined to the plane of delineation. The point V in the figure is the vanishing point of the line AB, being found by the line EV, drawn from the eye of the spectator parallel to it, and produced till it touches the plane of delineation in the point V. For a similar reason, V is the vanishing point of the line CN ; it is also the vanishing point for any other line parallel to the line CN, as BA ; all parallel lines having the same vanishing point. The point Z is the vanishing point of the line AK, being obtained by a line drawn from the eye parallel to the line AK, and produced till it touches the plane of delineation. The point Z, moreover, is the vanishing point of the original lines DF and NH. And it is to be recollected by the student, that there will be as many different vanishing points of lines in the delineation of an original object as there are different directions of lines in that original object. The point Y is the vanishing point of the parallel original lines DN and FH, being found by the line EY being drawn from the eye parallel to them till it touches the plane of delineation. So also Q is the vanishing point of the line CD. In the process of perspective delineations, as we shall presently see, the plan of the object being drawn, the places of the various vanishing points are found on the ground line, whence they are transferred to the horizontal line by means of perpendiculars raised from them.
  15. *A vanishing line* is one supposed to be made on the picture by a plane passing through the eye of the observer parallel to any original plane produced till it touches the picture. The line VZ is the vanishing line of an horizontal plane, and of all horizontal planes, being found by the intersection of a plane passing horizontally through the eye, or parallel to an horizontal plane. The vertical line YVM is the vanishing line of the original vertical plane, ABCDN being the line where a plane passing the eye of the spectator parallel to that plane would touch the plane of delineation. There will be as many different vanishing lines on the plane of delineation as there are different positions of planes in the object or objects ; and

all parallel planes will have the same vanishing line. Similarly, all lines lying in the same plane will have their vanishing points in the vanishing line of that plane. All planes or lines in an original object which are situated parallel to the plane of delineation can have no vanishing lines or vanishing points on the plane of delineation.

16. A *visual ray* is an imaginary right line, drawn from the eye to any point of observation. EA and EY, &c. are visual rays, being right lines drawn from the eye to the points A and Y. Hence a number of visual rays directed to every part of an object will form a pyramid of rays, whereof the eye is the apex, and the object the base.
17. A *perspective delineation*, then, is the section of a pyramid of rays producing a perspective projection, and is most commonly considered as being made between the object and the eye. But the section of rays may be taken when they are extended beyond the object; in which case such a section is called a *projected* perspective representation of the object.

2407. It will then be seen that a knowledge of perspective is, as Addison has said, a knowledge of "the science by which things are ranged in picture, according to their appearance in their real situation."

2408. The situation of the objects being given with the plan and position of the plane of delineation and the height and distance of the eye of the observer, the delineation of such objects is truly determinable by rule. The mechanical operations necessary for this purpose form the subject of what follows. It is however necessary, before proceeding to lay them before the reader, to premise that he must thoroughly study and understand the preceding definitions before he can proceed with profit to himself, and we recommend a repeated perusal of them until that be effectually accomplished.

2409. Example I. In *fig.* 830, No. 1., we have the plan of the original object

EBADCF, whereof ABCD is a cube, and BCFE a double cube, that is, twice the height of CBAD. GL is the plan of the ground line; S, the station point. Through S draw XY parallel to the plane of delineation GL, and draw SG and SL respectively parallel to the sides EA and AD of the united cubes ABCD and BCFE; and these produced to meet

the plane of delineation will determine the vanishing points (Def. 14.) of the horizontal lines AE and AD, and of all other horizontal lines parallel to them. Draw the line SO perpendicular to GL, which line being the direction of the eye perpendicular to the plane of the picture determines the point thereon to which the eye should be directly opposite to view it when completed, showing also how much of the object is on one side, and how much on the other of the point of view. We have now to draw the visual rays SA, SB, SE, SF, SC, SD, cutting the plane of the picture or delineation in *b*, *x*, *w*, *c*, and *d*; the point A of the nearest cube touching, itself, the picture at that point. The preparation on the plan is now completed.

2410. The picture (No. 2.) or plane of delineation is to be prepared as follows:—First draw the ground line GL, and to such ground line transfer, by dropping verticals, the points *KxbwcA* and *d*. Above, and parallel to GL, at such convenient height as may be necessary to show more or less of the upper surfaces of the cubes or otherwise, as desired, draw the horizontal line VZ; mark on such horizontal line the point O, to which the eye is supposed to be perpendicularly opposite for viewing the delineation when completed. All the other preparations are obtained from the plan, and may be obtained as follows:—First set off on the horizontal line VZ the points V and Z, which are the vanishing points of the sides AE and AD respectively. As A, the nearest angle of the object, touches the plane of delineation, it is manifest that a line vertically drawn from that point will be of the same height as the object itself, that is, as the figures are cubes, equal to AB or AD in the plan No. 1. Take, therefore, AB No. 2. of the height required, and draw the lines BV and AV, also AZ and BZ, which being crossed by verticals carried up from *xbwcd* will determine the points *ke* and *i* at the bottom, and in *f* and *h* at the top, and *pq* and *r* in the part where the cube is double the height. Drawing *hV* it is intersected by the verticals from the visual rays at *c* and *w*, cutting in *g* and *n*. The line KK forms another line of heights, if desired, for finding the height Fg; indeed, by continuing any line BC (No. 1.) to K, intersecting the picture, a line of height may be obtained. The representation of the cube marked A will be understood without difficulty, if what has preceded be well comprehended. As by Definition 15. we have seen that all planes or lines in an original object situated parallel to the plane of delineation have no vanishing lines or points in the plane of delineation, so two of the sides of the cube will be bounded by horizontal and vertical lines, inasmuch as those sides lie parallel to the plane of delineation. The vanishing points for the other lines will of course be found in O, which passes through the picture at right angles to it from S, the station point.

2411. Example II. To find the representation of a quadrangular building, situated inclined to the picture, covered with a single spanned roof, having a gable at each end.

2412. Let the rectangle ABCD (No. 4.) (*fig.* 831.) be the plan of the building, the line EF will be the place of the ridge of the roof extending from end to end. Let the line QL be the place of the plane of delineation, and let S be the station point.

2413. Find O the centre of the picture, also the points Q and L, the vanishing points of the lines AB and AD, and their parallels, by lines drawn from S parallel to such lines, and intersecting the picture. Produce the face of the building AD to I for an intersection with the picture, and draw the visual rays intersecting the ground line of the picture in the points *beaf* and *d*. These need not, however, be drawn beyond the plane of delineation.

2414. Prepare the picture (No. 5.) by drawing the horizontal and ground lines VZ and GR at any distance from each other at pleasure; fix upon the centre of the picture O, and draw the vertical line OO; set off the distances of the vanishing points OV and OZ, equal the distances of the vanishing points OQ and OL in No. 4. Draw the intersecting line IL (No. 5.), and all the visual lines, through the points *beaf* and *d*, taken from their respective places and distances *beaf* and *d* (No. 4.), and proceed as follows:—

2415. On the intersecting line IL (No. 5.) set up the height IK equal to the height of the building BC or HG (Nos. 1. and 2.), and draw the lines KZ and IZ, determining the plane *gmop* for the front of the building. Draw the lines *mV* and *gV*, determining the end of the building *ghim*. It now remains to place the roof, which is readily done, but which, however, requires some circumspection in the process.

2416. Place the height of the roof XD (No. 1.) on the intersecting line at IL (No. 5.), and draw LZ, which will give the height of the roof on the angular line of the building *gm* at *r*; from which spot it may readily be transferred to its proper place in the visual line *ek* by the line *rV*, which cuts the line *ek* in the point *k*, the point required. From the point *k* draw the lines *ki* and *km*, completing the gable end of the building. Draw the ridge of the roof *kZ*, cutting the end visual line, in the point *n*; and lastly, draw the line *no*, completing the whole linear delineation of the building *ghiknop*. It is to be observed, that whatever original plane is produced to the picture to obtain an intersection, such intersection serves only to obtain heights in the direction of that plane; whence they may be transferred to other planes in contact with it, as in the present instance. The intersecting line IL (No. 5.) is the intersecting line of the plane *gmop*; hence any original height set up

thereon can only be transferred throughout the direction of that plane. Thus the height of the roof  $IL$  was transferred by the line  $LZ$  along that plane to its other extremity  $s$ ; but the line  $rs$  is not the place of the ridge of the roof, which lies in the middle of the plane  $ghikm$ , proceeding from the point  $k$ ; but any height on the angular line  $gr$  is easily transferred along that plane by means of its horizontal vanishing point  $V$ , by which means the height of the roof was obtained by the line  $rV$  at  $k$ . If, instead of the plane over the line  $AD$  (No. 4.) being produced for an intersection, the plane of the middle of the house in the direction of the ridge of the roof had been drawn, and the height of the roof had been set up on that line, it would at one application be transferred to its proper place.

2417. Let the line  $FE$  (No. 4.) be produced to  $P$  for an intersection, set off the distance  $OP$  at  $OP$  (No. 5.), and draw the intersecting line  $PR$ . On  $PR$  set up the height of the ridge of the roof equal  $XD$  (No. 1.), and draw the ridge line  $RZ$ , and it determines the exact ridge of the roof between the proper visual lines, and will be found to correspond exactly with the ridge obtained by the former process.

2418. The roof may, however, be found by another process, thus:—The slant lines of the roof have their vanishing points on the picture as well as any other direction of lines in the same object. The line  $km$  (No. 5.) being in the vertical plane  $ghikm$ , will have its vanishing points somewhere in the vanishing line of that plane. (Def. 15.) A vertical line drawn through the horizontal vanishing point  $V$  will be the vanishing line of the plane  $ghikm$ ; therefore the vanishing point of the lines  $km, ki$ , and of all lines parallel to them, will be somewhere in the vertical  $GVXQ$ .

2419. Two lines drawn from the eye parallel to any two lines in an object, finding their vanishing points, will make the same angle at the eye as the lines in the object make with each other; for the two lines in the one instance are respectively parallel to the two lines in the other.

2420. The line  $SQ$  is drawn from the station  $S$  parallel to the line  $AB$  (No. 4.), and a line drawn from the station  $S$ , making the same angle with  $SQ$  as  $ED$  does with  $EC$ , (No. 1.), will find the vanishing point of the line  $ED$ , and this point must be evidently somewhere in a vertical line through the point  $Q$ . To obtain this point in practice, take the distance of the vanishing line it is in, that is, the length from  $S$  to  $Q$  in the compasses, and set off the same in the horizon (No. 5.) from  $V$  to  $W$ . At the point  $W$  make an angle  $VWX$  equal to the inclination of the roof, that is, equal to the angle  $CED$  (No. 1.), and

produce the line till it intersects the vertical line through the vanishing point V in the horizon in the point X. The point X will be the vanishing point of the line of the roof *km* (No. 5.), and of the line *no*, parallel to it. The slant lines of the roof *km* and *no*, already obtained, will, on application of a ruler, be found to tend to the point X, as above stated.

2421. In the same way the line of the roof *ki* (No. 5.) will also have its vanishing point, and in the same vertical line GVQ. It will be found to be as much below the horizontal vanishing point V as the point X is above it. (Def. 14.)

2422. Let the line AB (No. 6.) be the line of the horizon, and CD the vanishing line of a vertical plane, being the gable end of a house, and let the angle ABC be that of inclination, finding the vanishing point of the slant lines of a roof in one direction. Let the line BD be the line, finding the vanishing point of the slant lines in the other direction, having the same inclination to an horizontal line; then the angle ABD will be equal to the angle ABC, and the distance AD equal to the distance AC.

2423. Example III. To find the representation of a quadrangular building situated inclined to the picture, covered with a single hipped roof.

2424. Let the quadrangle GDHK (No. 7.) be the plan of the building; the line MN will represent the ridge of the roof. The former line QL may be the place of the plane of delineation, and it may be viewed from the same station S. The position and direction of the lines of this object being the same as those of the last example, the preparatory lines will also answer for this. We have then only to draw the visual rays MS, NS, CS, PS, and KS, intersecting the picture in the points *m*, *n*, *g*, *p*, and *k*, and to produce the line DG for an intersecting point at R.

2425. Prepare the picture (No. 8.); let the line VZ be the horizon, GR the ground line, O the centre of the picture, and the points *m*, *n*, *g*, *p*, and *k* corresponding with *m*, *n*, *g*, *p* and *k*. (No. 7.) Draw the visual line lines through those points and the intersecting point R, and proceed as follows:—

2426. On the intersecting line RE set up the height RT, equal the height of the object HG (No. 2.), and draw the lines TV and RV, cutting the visual lines of the front of the building in the points *z* and *o*, *y* and *p*, determining the plane *ypoz* for the representation of the plane of the front. From the angular points *z* and *y* draw the lines *zw* and *yx* to their vanishing point Z determining the plane *yzwx* for the end of the building.

2427. On the intersecting line set up the height of the roof TE equal the height NK (No. 3.), and draw EV cutting the angular visual line of the building in the point *e*, from which point draw the line *ez*, cutting the visual line *pa* in the point *a*, the point of direction of the ridge of the roof. Draw the line *aV*, which, cutting the visual lines through the points *m* and *n* in the points *t* and *v*, determines the exact position of the ridge of the roof *tv*, which is the representation of OP (No. 3.), or of the ridge MN (No. 7.); draw the lines *to*, *vz*, and *vw*, which will complete the whole representation required. In No. 8., if the lines *az* and *aw* be drawn, they will form a gable end *yzawx*, of which the point *a* is the point of the gable, and will answer for the direction of the ridge, whether it be a gable end or a hipped roof, for in both cases it lies in the middle of the breadth of the house; wherefore the line *aV* answers as well the edge of a hipped roof as of a gable end.

2428. In examining the plans (Nos. 4. and 7.) of the two buildings, it will be seen that they are placed at right angles to each other, and in contact at the point D, so that the second example might have been easily accomplished from the first, without the aid of another intersection and other preparatory lines, than the additional visual rays from the angles, which the student will have surely no difficulty in carrying through, without the necessity of encumbering these pages with the detail.

2429. Example IV. In fig. 832. No. 1. is the general plan of a church similar to many country churches. ABCD is the main body of it; EFGH its tower; IKLM and MLNO subordinate parts of the building, and *abcd* the porch. No. 2. is its geometrical elevation; the ends and measurements, AB and BC, answering to IM and MO in No. 1., and the points of the roofs D, E, and F. (No. 2.) answering to the lines of the ridges QR, TV, and PL, No. 1. To find the perspective representation of this building on the plane of delineation YZ, the station being at S, the following is, perhaps, the readiest process.

2430. Find the vanishing points Y and Z of the horizontal lines of the building by the lines SY and SZ being drawn from the station parallel to them. O is the centre of the picture. Draw the visual rays from the visible angles of the object in direction to the station S, to intersect the plane of delineation.

2431. When a complicated object, that is, one composed of many parts, is to be drawn, it requires, of course, a great number of visual rays for the precise determination of those parts, and the whole together forms an apparently confused number of lines. The eye, however, which views them properly, does not perceive that confusion; and, if it perplex the student, different coloured inks, or of different shades of depth, may be used to particularise different parts. In the delineation of such an object as the present example, the most important consideration is the choice of a proper intersection; for though any inter-

Fig. 852.

section will do, that should be chosen which unites most parts in its direction with the greatest exactness and the least trouble. In the case under consideration, none seems more eligible than the direction of the roof PLM, which produce to W.

2432. In the picture No. 3., GL is the ground line, GV the height of the horizon, the line VX being then the horizontal line. O in the horizon is then the centre of the picture, from which, place the distances of the horizontal vanishing points OV and OX equal OY and OZ, No. 1. AB (No. 3.) is the intersecting line, and all the visual lines on the plane of delineation are drawn conformably to their intersections on the ground line in the plan. On the intersecting line the height AC is made equal to the height AG of the elevation No. 2.; and the lines Cc and Aa, being drawn in direction to the vanishing point V, determine the height *ac*; being the height of that part of the building on the visual line answering to the ray from the point M in the plan No. 1. Through the points *a* and *c* draw the lines *de* and *bf* to their vanishing point X, determining the plane *bdef*, the representation of the plane AGHC, No. 2.; the visual lines *bd* and *fe* answering to the rays from the points I and O in the plan. Draw the lines *dh* and *bg* tending to their vanishing point V, to the ray from K in the plan completing the plane *bghd*. On the intersection make the height AD equal to the height of the roof NE of the elevation No. 2., and draw Di in direction to V. Through *i* draw the line *kl* to the vanishing point X, touching the visual lines of the roofs in the points *k* and *l*. Draw the lines *km*, *mh*, *kd*, *kc*, *lc* and *le*, which will complete the whole of the structure over the plan IKNO, No. 1.

2433. The height of the roofs of the low buildings is equal to the height of the upright walls of the body of the building, as shown by the line PR in the elevation No. 2.; hence, the line *mo*, and the return line *on*, may be drawn to the visual lines corresponding with the intersections from the angles A and B of the plan. From the angle *g* the line *gs* may also be drawn, which will determine the lines *sr*, *rt*, and *tp* of the porch. Make AE on the intersection equal to the height of the roof BF in the elevation, and draw the line EV determining the ridge of the roof between the two visual lines from the points P and L of the plan. Draw the lines of the gable end *ro* and *rz*, the point *z* being obtained by the line *om* drawn to its vanishing point X, cutting the visual line from the angle D of the plan in the point *z*.

2434. Make AG and AF on the intersection equal to the heights of the tower BO and BM of the elevation, and draw the lines GV and FV cutting the visual line from P in the plan, in the points *a* and *b*; through which points draw the lines *ac* and *ef* to their vanishing point X; and the lines *cd* and *eg* to their vanishing point V; the points *g*, *e*, and *f* being in the proper visual lines from the angles of the tower F, E, and H in the plan. The tower will be completed by drawing the lines *dg*, *de*, *ae*, and *af*.

2435. This example elucidates the general practice of vanishing points, which are as well to be obtained of other positions of lines as horizontal ones. It is not always that the vanishing points of inclined lines are required, but they are often useful, and sometimes absolutely necessary. In the geometrical elevation No. 2. the lines MO, PF, GD, IE are all parallel lines, as also are the lines OV, FR, EH, and DI, and though situated in different, yet they are in parallel planes, and will therefore have a common vanishing point. A line drawn perpendicularly to the horizon through the vanishing point X (*fig. 3.*), as LQ, will be the vanishing line of the plane of the end of the church over the line IO of the plan, also of the end of the body AD, likewise of the side of the tower EH; and a line drawn through the point V (No. 3.) perpendicularly to the horizon, as GM, will be the vanishing line of the planes over the lines (No. 1.) IK, AB, *ab* of the porch, and FE of the tower, and all lines in those planes, or the boundaries of those planes, will have their vanishing points somewhere in those vanishing lines.

2436. To obtain the vanishing points of the inclined lines of the roofs and tower, take the distance of the vanishing point Z from the station S in the compasses, and apply it on the horizon from X to H. At the point H make an angle with the horizontal line equal the angle of the roofs aPc (No. 2.); the curve KI and the distance of it from the centre H being equal to the curve *ac*, and distance of it from its centre P: then is the angle KHI equal to the angle of the roof aPc (No. 2.). Produce the line HK to Q; Q will be the vanishing point of the line *ea* of the tower, also of the parallel lines *ov*, *dk*, and *cl*, which, though obtained by a different process, will all be found, by application of a ruler, to tend truly to that point, as is shown by the dotted lines in the example. Proceeding in the same way with the distance of the vanishing point Y from the station S, we obtain the vanishing point of the same inclination of lines in the other planes of the object. Take the length SY in the compasses, and set it off on the horizon from V to N. At the point N make an angle INT on the horizon equal the angle KHI, that is, equal the angle of inclination of the roof aPc (No. 2.). The line NT produced to M in the vanishing line GM will be the vanishing point of the line *de* of the top of the tower, also of the lines *w3* and *y5* of the porch (the inclination of the roof of the porch being the same as the other roofs of the body of the church), as shown by the dotted lines in the example. The walls of the porch are obtained from the height AP on the intersection, equal the height AT, No. 2., Pm being drawn to the vanishing point V, and *mn* to X, give the lines *n5*, *53*, and *32*. We may observe that the inclined lines *af*, *le*, *kc*, and *vz* have a common vanishing point, which, if required, may be obtained; it will be in the same vanishing line with the point Q, and as much below the horizontal vanishing point X as the point Q is above it, to which point, were it obtained, the lines already drawn will be found exactly to tend. It is seldom absolutely necessary to have both those points; in this instance one only of them, the point Q, is obtained, which answers every end required of both; for, supposing it were left to that vanishing point for finding the inclined lines, the visual lines being drawn, and the heights of the upright walls being found, the line *dk* being drawn in direction to the vanishing point Q determines one side of the gable end at the visual line in the middle; the other is accomplished by joining the points *k* and *c* together. So of the other gable, *cl* being drawn, *le* is also had by joining together the points *l* and *e*.

2437. To complete the whole, draw the line *xq* on the tower from the point *x* to the angle of the tower, in direction to the vanishing point Q; then draw the lines *qh* and *nh* to their proper visual lines and vanishing points V and Q. The putting on of the spire requires some consideration, and in it we must proceed with some thought and care. The base of it is intended to be a regular octagon. If the two external lines in the geometrical elevation of the spire be continued till they touch the sides of the tower, as is done at K and L (No. 2.), and an octagon be there constructed, extending the square of the tower, it will be the base of the spire. Set up the height of the spire BW (No. 2.) on the intersection (No. 3.) at B; also the height of the base line KL at R, and draw the lines BV and RV; the first, cutting the visual line through the centre of the tower in the point O, determines the height of the spire; the other, cutting the tower in the point *u*, determines its base. Through the point *u* draw a line round the tower, and find the points of the octagon in the middle of each face of the tower, to which let lines be drawn from the top O, and the whole will be completed, as shown in the example.

2438. Thus have we gone through the process of finding the representation of rather a complicated object with as little confusion of lines as possible; but one thing succeeding another, and each being required to remain for the student's observance, the whole unavoidably becomes intricate. Indeed, it is not now so perfectly executed but that

dition of the trees to their right and left. Let visual rays be drawn from the trees on both sides to the station S. The angle CSD is the angle of view under which the whole extent is seen, and the rays CS and DS are denominated the extreme visual rays of the view.

2445. Objects may not only be placed too near the eye for comfortably viewing them, but they may be so nearly placed to the eye as to give it pain. The eye only contemplates a small portion at a time; it is only by its celerity and continual motion that it becomes perfectly sensible of a whole and of the many forms whereof it is composed. But when an object, or many objects, widely extended, are placed too near, the traverses of the eye in viewing the whole become painful. Every one must have experienced that this is so, and why so we must leave to others to account for. When the eye is removed to an agreeable distance, the extent of the view to be delineated is at once seen without turning the head to one side or the other, so that all the objects are at once comprehended.

2446. In taking a view, the turning of the head is to be avoided. The view should on no account comprise a greater extent than can be taken by a *coup d'œil*, or than can be viewed by the traverse of the eye alone; and this necessarily confines the extent of that with which we have to deal, and brings the angle of view within certain limits. What the eye can contemplate without trouble it views with pleasure, and beyond a certain extent the eye becomes distracted.

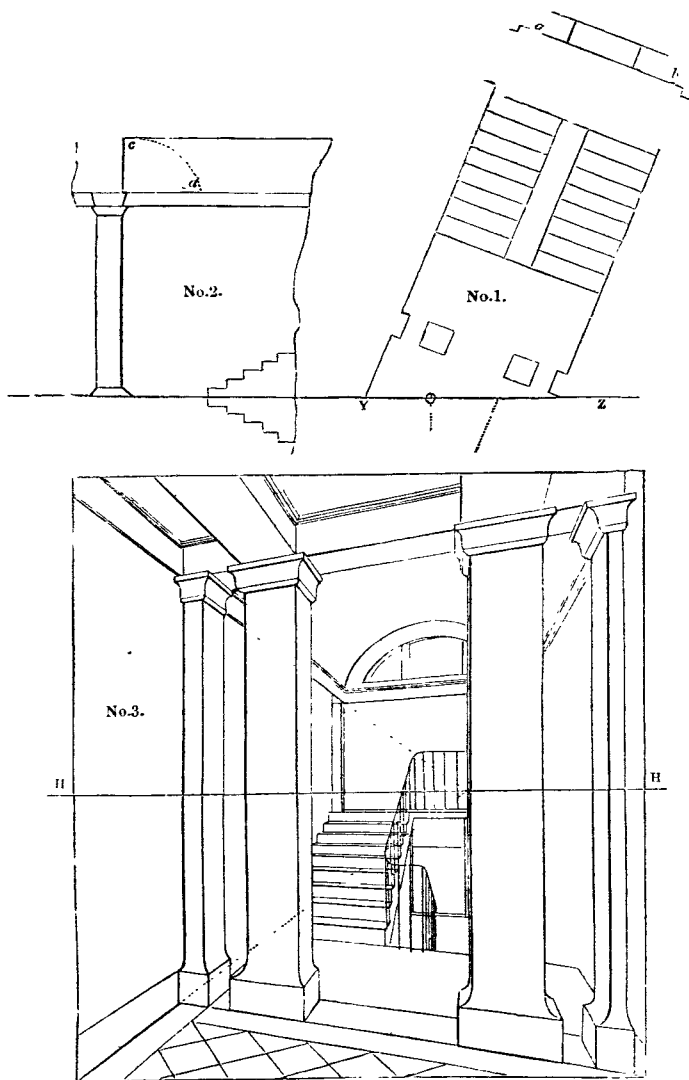

2447. Smallness of object has no relation to the angle of view; a die, or the smallest possible object, may be brought so near the eye as to give pain in looking at it, and a large extent of view may be contemplated with as much ease as a small one, by merely placing the larger one at a greater distance. If the place of the plane of delineation be at FG, then FSG will be the angle of view. If a section of the same visual rays be taken at HI, then HI will be the extent of the picture, and the angle HSI is the angle of view; but the angles FSG and HSI are the same, therefore the eye views both with equal satisfaction: but in this case one must be placed at the distance SO, and the other at the distance SP.

2448. The attempt to select an angle suitable to all the cases that may occur, as the best angle of view, would be as vain as it would be absurd. Different subjects require different treatment. External subjects differ from internal ones; and the last from each other, according to circumstances. Some authors on the subject have laid it down as a rule, that the greatest distance of the eye from the picture should not exceed the width of the picture laterally, which makes the angle of view about 53 degrees; others have insisted that the distance should be less, requiring that the angle of view should not be smaller than 60 degrees; and others allow of a still larger angle. The elder Malton, and his son, to whom we are indebted for all that is valuable in this section, and whose (both of them) experience in the matter was very extended, advise that the angle of view should never exceed from 53 to 60 degrees; the former recommending an angle of 45 degrees as the best, because neither too large nor too small. The elder Malton advises to keep between the one and the other, that is, not to let the angle of view exceed 60 degrees, nor be less than 45, the first being likely to distort the objects, and the last rendering them too tame in the outline. We can add, from our own experience, that the advice is sound; for though, under very particular circumstances, it may be necessary to use a larger angle of view than 60 degrees, such a case does not frequently occur. Much must always be left to the discretion of the artist in respect to points which are to guide the angle of view he adopts. After a little experience, he will find that angle best suited to the circumstances under which his drawing is to exhibit the object or objects.

2449. Example VII. The principles upon which we delineate any of the interior parts of a building are in no wise different from those used for the representation of their external views, for it is of course immaterial whether we represent the external faces of their sides, or those which form their internal faces; the only difficulty which arises in making an internal view being that which arises from the inability, on account of the restricted distance under which they are in reality viewed, of placing the station point at such a distance as to take in a sufficient quantity of the objects to be represented. A person placed in a room can of course only see the whole of one and part of another wall; in short, in every direction he cannot see comfortably more than, as we have above mentioned, forty, or, at the most, fifty, degrees of the objects around him. On this account, and for the purpose of showing more than in reality can be seen, it is customary, and perhaps justifiable, in order to give a more comprehensive view of the interior to be delineated, to place the station point of the spectator out of the room or place, supposing one or more of its sides to be removed. This is, in fact, a delusion, as is every view of an interior possessing any merit that has come under our notice. But for picturesque delineation, it is not only one which is necessary, but one without the practice whereof no satisfactory representation can be given of an interior whose dimensions are not very extended. The section whereon we are now engaged is not supposed to be a treatise on Perspective, but merely a general developement of its principles so as to give the reader such a general knowledge of the subject as may enable

him to pursue it, if he please, from the hints it affords. With this apology for not producing to him a more complicated, though not less useful subject, we proceed.

2450. *Fig. 836.* (No. 1.) represents the plan of a staircase one third the size used for the

*Fig. 836.*

purposes of the delineation ; YZ (No. 1.) is the plane of the picture, O is its centre. From the data, therefore, there will be no difficulty of obtaining the vanishing points of the sides Ya and ab. The diagram is not encumbered with the visual rays necessary for the delineation, which we are to suppose drawn and transferred to their proper places on No. 3., wherein HH is the horizontal line. No. 2. is a longitudinal section of the staircase, wherein are shown the rising and descending steps, and the dotted line cd gives the section of the vaulted ceiling over the staircase. It will be immediately seen that the ends of the steps will be determined by visual lines, notwithstanding the ascent and descent of them, because either is determined by referring to any lines of height, which may be obtained from the plan and section, by which the portions seen of the flights will be immediately found and

transferred to their respective places on the picture. With these observations we leave the diagram for the exercise, on a larger scale than here given, of the ingenuity of the student.

2451. Example VIII. The last perspective example to be submitted is that of a cornice

Fig. 837.

(fig. 837.), wherein the contrivance of the elder Malton is used for finding the places of the modillions and the other parts.

2452. Let EM, FN, GO (No. 1.) represent the angles of a building in perspective, LMNO being the lower horizontal line of the cornice, whose geometrical elevation and profile are shown in No. 2. Make MQ equal to  $mq$  the depth of the cornice, supposing the edge EQ to be in the plane of projection; draw PQRS, &c., the lines of the top of the cornice, to their respective vanishing points. Make QT, QT' in RQ, PQ, produced equal to the perspective projection of the cornice  $qt$ . Then place the depths of the various mouldings along MQ, and fix the lengths of their projections on the lines drawn to the vanishing points through those in EQ, an operation which may be much facilitated by drawing MT, MT', by which, in many places, the points of the mouldings are at once determined, as in the case of the top and bottom of the fillets of the ovolo; and very often, if the drawing is not on a very large scale,  $mt$  and its perspective images MT, MT', &c. will enable the eye to proportion the mouldings. Thus the perspective projections MQT, MQT' of the sections of the cornice by the planes of the sides EN, EL, supposed to be prolonged or extended, may be found; and it is manifest that lines through the points of these sections to the proper vanishing points will give the perspective forms of the cornice mouldings as they would appear.

2453. The lines found will by their intersections supply the mitre MQU; but where the scale is large, it is better to obtain mitre sections at each principal angle of the building as shown by the lines MQU, NRX, &c. The planes of the mitres form, of course, angles of forty-five degrees with the sides of the building itself, consequently the vanishing points of QU, RX, &c. may be found by bisecting perspectively the right angles found, or by drawing on the plan lines parallel to the diagonal lines or mitres from the station point to intersect the picture. If these, indeed, are found in the first place, there would be no necessity to draw the square sections MQT, MQT', inasmuch as lines drawn from the mouldings intersecting the mitre sections to the vanishing points will at once form the perspective representation of the cornice. In practice, this is the usual mode of proceeding, because a skilful draughtsman can pretty well proportion by his eye most mouldings as seen in perspective; but where great accuracy is required, the method of proceeding by square sections is recommended, because, from the great foreshortening of the diagonal line, the smallest inaccuracy of intersection on it will cause very large errors in the mouldings.

When the diagonal sections alone are used, it is clear that the geometrical profile, No. 2., will not be the same as that formed by the oblique section of the cornice: this last must therefore be obtained from a plan and elevation of the mouldings as shown in No. 3.

2454. Instead of finding the square section made by the plane FNGO at the angle OG, it may be drawn on the plane TQM, where it is more readily found by producing the lines whereby the section TQM was obtained; so the lines T'T'', MO'' are set out in perspective equal to the projection of the break of the building ON: moreover by the line T'O'' we may obtain the mouldings of the cornice on the face of the wall GH as produced

**Fig. 837. a.**

is this. Let A (*fig. 837 a.*) be the vanishing point, CDB a segment of a circle whose centre is A; then if CB be bisected in D, AD will be a vanishing line for such bisection; and if CD be bisected, and a ruler applied to join CD, it will, by the application of a square on CD, give the vanishing line for the new bisection.

**Fig. 837. b.**

2945. Our next case is to find the *starting point* of the *sinking* of *liberty*, which may be found here what Engels already has found: a *disproportion* of *social* forces, here the *bourgeoisie* and *proletariat* and *land* where *the* *bourgeoisie* and *proletariat* *struggle* for the *power* of the *land* where *the* *bourgeoisie* *want* of *room*, be done in the present example, is taken through the line *oo*, No. 2., passing through the extreme left

2456.  $\therefore$  Hence that section, if found in perspective at OS, cannot be used for drawing the perspective representation of the pediment cornice, except for the bead or fillet above the corona, which, from the construction of the pediment, will coincide at this mitre, as we may see in No. 2.; whence it may also be seen that the point  $x$  does not coincide with  $z$ .  $X'x$  cannot, therefore, in the perspective representation, be drawn through  $X$ , the point answering to  $z$  in the diagonal section NRX.  $OO'$  in the line OH is to be made in perspective equal to  $mo$ , No. 2., and the whole depth  $oo$ , and those of the several mouldings on the oblique section, being set upon EQ produced, they are to be transferred to  $OO'$  by means of the vanishing points. The distance  $O'I$  is the perspective distance of the projection  $o'$  of the cornice as before, and is most readily obtained from the section  $O'T''$ , which is transferred to the plane  $O'I$ , and will be easily comprehended from the figure; the quantity of projection of each raking moulding of the pediment is equal to that of the same moulding where horizontal. Thus the perspective representation of an oblique section made by a plane passing through  $oo$ , joint through the various points, the modillions, their representations are but if no plan is used, the following

method, invented by the elder Malton, may be adopted:—  
2457. Draw BC the line intersecting the plane of the  
point  $x$  in MQ, and transfer it to the line BC as in No. 3, to A,  $x$ , and transfer A to the line BC as in No. 2. Then set off the proportional widths and intervals of transfer them by means of the same proportioning point by which  $x$  was transferred to 1; and from the points 2, 3, 4, 5, 6, &c. in  $xy$  thus obtained, draw on the perspective of the soffit by the use of the vanishing point the lines representing the tops of the modillions corresponding to 2, 3, 4, &c., No. 2. The cymatium round them and the inner angle of the soffit may be drawn by the eye, or where great accuracy is required, the mitre or diagonal sections may be determined as for the principal mouldings already described. At the backs of the modillions the verticals are to be determined either by means of visual rays from a plan, or through the medium of intersections of the perspective lines of the upper parts of them on the soffit, which is as much as can be requisite for guiding in a general delineation. The same process is to be used for the modillions at the other side.

**Fig. 837. c**

The following is an easy method for drawing vanishing lines in perspective. Let  $AB$  ( $CD$ ) be the perspective representation of two parallel lines in a horizontal plane. It is required to divide the given portion of  $AB$  on one of them so that its parts shall be the perspective representation of equal portions of the equal line (or in any assigned ratio). Draw  $BC$  parallel to  $CD$  and equal to  $AB$ , and divide it into the required number of equal parts in the parts in the desired proportion. Draw  $AC$  and divide it into the same number of equal parts. From  $F$  draw lines to each of the points of subdivision  $pqr$  on  $BC$ , which will cut  $AB$  in the required points of subdivision  $pqr$  on  $AB$ .

### SECT. III.

**SHADOWS.**

2458. **Sciography**, or the doctrine of shadows, is a branch of the science of projection, and some preparation has been made for its introduction here in Sect. VI. Chap. I. (1110, *et. seq.*) on Descriptive Geometry, which, if well understood, will remove all difficulty in comprehending the subject of this section.

2459. The reader will understand that in this work, which is strictly architectural, the only source of light to be considered is the sun, whose rays, owing to his great distance, are apparently parallel and rectilinear. It is moreover to be premised, that such parts of any body as may be immediately opposed to the rays of light are technically said to be *illuminated*.

light, and the remaining parts of such body are said to be *in shade*. But when one body stands on or before another, and intercepts the sun's rays from the latter, which is thereby deprived of the action upon it of the rays of light, the part so deprived of the immediate action of the light is said to be *in shadow*. It seems hardly necessary to observe, that the parts of any body nearest the source of light will be the brightest in appearance, whilst those furthest removed from it will, unless under the action of reflected light, be the darkest.

2460. It has been the practice, in architectural drawings, to represent the shadows of their objects at an angle of forty-five degrees with the horizon, as well on the elevations as on the plans. The practice has this great convenience, namely, that the breadth of the shadow cast will then actually measure the depth of each projecting member which casts it, and the shadowed elevation may be thus made to supply a plan of the external parts of the building. Now, if in the elevation the shadows be cast at an angle of forty-five degrees, it will on a little consideration be manifest, that, being only projections of a more lengthened shadow (for those on the plan are at an angle of forty-five degrees), the actual shadow seen diagonally must be at such an angle as will make its projection equal to forty-five degrees upon the elevation; because all elevations, sections, and plans, being themselves nothing more than projections of the objects they represent, are determined by perpendicular, horizontal, or inclined parallel lines drawn from the points which bound them to the plane of projection, and similarly, a shadow in vertical projection, which forms an angle of forty-five degrees with the horizon, can only be the representation on such projection of an angle, whose measure it is our business now to determine.

2461. In the cube  $ABCDEFGH$  (*fig. 838.*) the line  $BD$ , forming an angle of forty-five degrees with the horizon, is a projection or representation of the diagonal  $AH$  on the vertical plane  $ABD$ ; and our object being to find the actual angle  $AHB$ , whereof the angle  $ADB$  is the projection, we have the following method. Let each side of the cube, for example, = 10. Then (by 907.)  $AD^2 + DH^2 = AH^2$ ,

Fig. 838.

That is,  $10 \times 10 + 10 \times 10 = 200 = AH^2$ , consequently  $AH = 14.142100$ .

As  $BAH$  is a right angle, we have by Trigonometry, using a table of logarithms, —

As $AH (= 14.142100)$ or Ar. Co. Log.	9.8494850
To tangent $45^\circ$	10.0000000
So $AB (= 10.0000000)$ log.	1.0000000

To tangent of angle  $FHB = 35^\circ 16'$  . . . = 9.8494850

The angle  $ABH$  is therefore  $54^\circ 44'$ .

Hence it follows, that when shadows are projected on the plan as well as on the elevation, at an angle of forty-five degrees, the height of the sun which projects them must be  $35^\circ 16'$ .

2462. It is of the utmost importance to the student to recollect this fact, because it will be hereafter seen that it will give him great facility in obviating difficulty where confusion of lines may lead him astray, being, in fact, not only a check, but an assistance in proving the accuracy of his work.

2463. We now proceed to submit to the student a series of examples, containing the most common cases of shadowing, and which, once well understood, will enable him to execute any other case that may be presented to his notice.

2464. In *fig. 839.* we have on the left-hand side of the diagram the common astragal fillet and cavetto occurring in the Tuscan and other pilasters, above in elevation and below in plan. The right-hand part shows the same connected with a wall, whereon a shadow is cast by the several parts.  $LL$  is a line showing the direction of the light in projection at an angle of forty-five degrees. It will on experiment be found, by a continuation of the line, or by one parallel to it, to touch the side of the astragal at  $a$ , whence an horizontal line drawn along it will determine its line of shade. We here again repeat, to prevent misunderstanding, that in the matter we are now attempting to explain we are not dealing with reflected light, nor with the softening off of shadows apparent in convex objects, but are about to

Fig. 839.

determine the mere boundaries of *shade* and *shadow* of those under consideration. The rest must be learned from observation, for the circumstances under which they are seen must constantly vary. This, however, we think, we may safely state, that if the boundaries of shade and shadow only be accurately given in a drawing (however complex), the satisfaction they will afford to the spectator will be sufficient, without further refinement. But it is not to be understood from this that we discountenance the refinement of finish in architectural subjects; all that we mean to say is, that it is not necessary. To return to the diagram: it is manifest that if the boundary of *shade* be at *a* from that point parallel to the direction of the light a line *ab* will determine the boundary of *shadow* on the fillet at *b*, and that from the lower edge of such fillet at *f* a line again parallel to the direction of the light will give at *c* the boundary of the shadow it casts upon the shaft *S*. As, in the foregoing explanation, *a* was the upper boundary of shade, so by producing the horizontal line which it gave to *a* on the right-hand side of the diagram we obtain there a corresponding point whence a line *aa'* parallel to the direction of the light is to be drawn indefinitely; and on the plan a line *aa*, also parallel to the direction of the light, cutting the wall *WW* whereon the shadow is cast at *a*. From the point last found a vertical line from *a*, where the shadow cuts the wall on the plan, cutting *aa'* in *a'*, will determine the point *a'* in the shadow. The point *e*, by a line therefrom parallel to the direction of the light, will determine similarly the situation *e'* by obtaining its relative seat on the diagonal *cd*, which perhaps will be at once seen by taking the extreme point *d* of the projection of the astragal, and therefrom drawing *dd'* parallel to the direction of the light. From the line *dd*, drawn similarly parallel to the direction of the light, and cutting *WW* in *d*, we have the boundary of the shadow on the plan, and from that point a vertical *dd* being drawn, the boundary of shadow of the extreme projection of the astragal is thus obtained. The boundary of shadow of the fillet on the right-hand side at *b*, similarly by means of *bb*, and by the vertical *bb'*, gives the boundary point of the shadow from *b*. The same operation in respect of *cc* gives the boundary of shadow from *c* to *c'* in the latter point. We have not described this process in a strictly mathematical manner, because our desire is rather to lead the student to think for himself a little in conducting it; but we cannot suppose the matter will not be perfectly understood by him even on a simple inspection of the diagram.

2465. In the diagram (*fig. 840.*) is represented a moulding of common occurrence in architectural subjects, and, as before, the right-hand side is the appearance of its shadow on the wall *WW* on the plan. It will be immediately seen that *LL* being the projected representation of the rays of light, the line *aa* determines the boundary of shadow on the ovolo, and that at *b*, the boundary of its shade, is also given by a line touching that point parallel to the rays, or rather projected rays, of light. On the right-hand side of the figure *oo'*, drawn indefinitely parallel to the direction of the light, and determined by a vertical from *a''*, the intersection by *a''a''* with the wall, will give *o'a''*, the line of shadow of *oa'*. The line *aa* determines the shadow on the ovolo, and this continued to *a'* horizontally gives also a like termination to *a''* in the shadow; *b*, the boundary upwards of the ovolo's shade, is represented to the right by *b'*, and to the right on the plan by *b*, whence by a vertical cutting the line *b'b''* in *b''*, the boundary of shadow which *b'* will cast is obtained. *cc* on the plan is in projection the distance of the line of shade *c'* from the wall whereon the shadow is cast, and its place in the shadow is at *c''*, *ee''b''* being the length of horizontal shadow produced by the circumstances.

In *fig. 841.*, which, it will be seen, is a common fillet and cavetto, *LL* is, as before, the direction of the

Fig. 840.

Fig. 841.

light, and *aa* gives the boundary of shadow, as well of the fillet's lower edge as of the lower edge of the cavetto itself. In respect of the right-hand side of the figure, *a'a'* is a line showing in profile the extent of projection of the fillet before the wall line *WW*, and from *a'* a line drawn indefinitely parallel to the direction of the light, and terminated by the intersection of a vertical from *a'* in *a''*, will give the point *a'* in the shadow. So is *bb* found through a vertical from *b* on the wall, by a line drawn parallel to the direction of the light from *b* on the plan. The several points being connected by lines, we gain the boundaries of the shadow, wherein *a'a'''* is represented by *a'a''*.

2466. *Fig. 842.* exhibits a fillet and cyma reversa or ogee, wherein, as before, *LL* is the direction of the light at a similar angle to that used on the plan. From the lower edge of the fillet, parallel to the direction of the light, is obtained the point *a* on the ogee, and from *b* a similarly parallel line gives the boundary of shadow in *c*. A line from *o* in direction of the light, drawn indefinitely, intercepted by a vertical line from *d'*, its projection on the plan in *d* determines *o'd*, the boundary of the shadow of the fillet on the wall *WW*. *cc'''* is the line of profile of the projecting boundary in elevation, of the shade of the ogee before the wall, whereon its shadow is terminated from *c* and *c'''* by a vertical *c''' c''*. *bb'*, the boundary of shade of the ogee itself, is found in shadow by the line *b'b'''* drawn indefinitely parallel to the direction of the light, and terminated by a vertical from *b'*, the point on the wall correspondent to *b* on the plan, the place of the shade's point in the elevation. By the junction of the lines so found, we shall have the outline of the shades and shadows cast. It is here to be observed, that the portion of light *a'b'* which the moulding retains is represented in the shadow by *a'b''*, all the other parts of its curved form being hidden, first by the projection of the fillet, and secondly by the line of shade *bb'*, which acts in the same way as the fillet itself in producing the line *aa'*, for the moment the light is intercepted, whether by a straight or curved profile, shadow must follow the shade of the moulding, whatever it be; and this is by the student to be especially observed.

Fig. 842.

2467. *Fig. 843.* exhibits the mode of obtaining the shadows and shade in the cyma recta. *LL* is the direction of the light, parallel whereto the line *ab* determines the line of horizontal shadow cast by the lower edge of the fillet upon the cyma, and *cd* that of the under part of the cyma itself upon the fillet at *d*. *ce'* is the upper boundary of the shade of the cyma, and *e* the point for determining the shadow of the lower fillet, the points *abcd* corresponding with *abcd* on the plan. *WW* on the right hand is the face of the wall, whereto the lines *ee'*, *dd'*, *cc'*, *bb'*, and *aa'* are drawn parallel to the direction of the light. From *e'd''c'b'a'* vertical being drawn, cutting the indefinite lines *oo'*, *a'a'*, &c. parallel to the direction of the light in *e''*, *d'''*, *c''*, *b''*, and *a''*, we have the form of the shadow in elevation. The part from *b'* to *c'* of the cyma being in light, its shadow will be the curve *c b''*, wherein, if it be required on a large scale, any number of points may be taken to determine its form by means of correspondent points on the plan as for the parts already described.

Fig. 843.

2468. *Fig. 844.* is the plan and elevation of some steps, surrounded by a wall, and *P* in the plan is a square pillar standing in front of them. It will be seen that the line *AB*

corresponds with *ab* on the plan, as do the points *E, F, G, H* with *efgh*, from which verticals determine them in the elevation. The projection of the plinth on the lower step is found by *KI* and a corresponding line and vertical, which, to prevent confusion, is not shown on the plan. The shadow of the square pillar *P* is found in a similar manner by the line *CD* corresponding to *cd* on the plan, the shadows on the steps being also determined by the points *L, M, N, O*, through the medium of verticals from *l, m, n, o*. The left-hand side of the shadow of the pillar is determined in a similar way by the line *pq*, and *QR* in the elevation is given by *qr* in the plan, and is the line representing the back *ps* of the top of the pillar. It will be observed that we have not described any of the preceding diagrams in a strict way, neither shall we do so in those that follow, presuming that the reader has, from the perusal of the section on Descriptive Geometry acquired sufficient knowledge to follow the several lines.

2469. The *fig. 845.* is a sort of skeleton plan and elevation of a modillion cornice, but deprived

Fig. 844.

Fig. 845.

Fig. 846.

of a corona, so as to show the shadows of the modillions, independent of any connection with other parts of the assemblage. *FG, HI*, and *AB* parallel to the direction of the light determine, by means of verticals from *d* and *i*, the points of shadows from the correspondent points *c, l*, the points *D, L*, and *I*, whereof *L* is the point of shadow of *M*.

2470. In *fig. 846.* we approach a little nearer to the form of a modillion cornice. The line *EF* determines the shadow of the corona, and *AB* by means of the lines *cd, Ik*, and the verticals *dD, kK*, the boundary of the side *HL* of the modillions. A line also drawn horizontally from *B* will give the under sides of their shadows. *FG* is a line representing the shadow of the corona.

2471. *Fig. 847.* gives the finished modillion, and the lines *Aa, Bb, Cc, Dd* will determine, by horizontal lines drawn from them, the shadows which we are seeking. The auxiliary lines, to which no letters are attached, cannot fail of being understood; but if difficulty arise in comprehending them, it will be removed by planning the several points, and therefrom drawing on the plan, to meet what may be called the frieze, vertical lines to intercept those from the correspondent points in the elevation, and the operation will be facilitated, perhaps, by projecting the form of the curved lines (as seen in the figure) whereof the modillion is formed.

Fig. 847.

2472. *Fig. 848.* will scarcely require a description. It is a geometrical elevation of the

Fig. 848.

Doric triglyph and frieze, with the usual accessories. AB gives the boundary of shadow on the femora of the triglyph, AC the boundary of shadow on the light sides of the glyphs, and AD of the shadow of the corona on the frieze.

2473. Fig. 849. is a skeleton representation of a three-quarter column, forming part of an arcade. The abacus is the mere block of material Ak. In the plan ab shows the length of the line of shadow AB, and is determined by the vertical bB. In the same way, CD is found by cd and the vertical dD. kG is the representation of kg on the plan, and by a vertical from g the line GH is also determined; H giving also by the horizontal line FH, in which H is already found, the situation of shadow of the point E of the abacus, as also by a vertical from f. LMN are places of the shadow of the column on the impost moulding of the arch, whereof two correspondent points are seen in l and n.

2474. The form of shadow of the console in fig. 850. will be seen on inspection to have been found from the lines aa, cc, dd, &c. on the elevation, corresponding with aa, cc, dd, &c. on the section, all which are parallel to the direction of the light, and sufficiently explain themselves.

2475. Fig. 851. is the elevation and section of a hemispherical niche, wherein are shown the shadows cast thereon by the vertical wall in which it is placed. Through the centre O draw DD at right angles to the direction of the light, and from O draw OA parallel to the direction of the light: A will be found the point in the wall casting the longest shadow. Produce AO indefinitely; and from a, the corresponding point in the section to A on the elevation, draw aa', parallel to it, which will cut the surface of the niche in a'. Draw the horizontal line a' a'' cutting AO produced in a'', and a'' will represent in the shadow the point A in the circumference. Take any other

point B in the edge of the niche, and by means of a line drawn therefrom horizontally we have the correspondent point of B in the section. From B draw in the direction of the light the line Bb'' b', cutting DD on the diameter in b''; transfer the point b''' in the elevation to b in the section, and draw bb' in the direction of the light indefinitely. Then with Bb'' as a radius from b as a centre, describe an arc cutting bb' in b'; and from b' draw the horizontal line b' b'', cutting Bb'' produced in b'', and b'' will be the point in the shadow corresponding to B in the elevation. To avoid the confusion which

Fig. 849.

Fig. 850.

Fig. 851.

would follow the description of the remainder of the operation, we have not encumbered the diagram with more letters of reference; the lines showing, on inspection, similar applications of the process for all parts of the curve. The fact is, that the whole of the shadow may be completed by taking the line DD as the transverse axis of an ellipsis, and finding the semi-conjugate axis Oa by the means above described, for Da"D is a semi-ellipsis in form, inasmuch as it is the projection of a section of a hemisphere. This example is applicable to the shadow of a cylindrical niche with a hemispherical head. The line NN shows the shadow of the portion of the head, and the remainder is obtained by the mere intersection of lines in the direction of the light from different points to the left of N, of which enough has been already given in the previous examples to make the application intelligible.

2476. *Fig. 852.* is the representation of a pediment wherein the section A is that of the

*Fig. 852.*

mouldings of the pediment at its apex. In the section, ab drawn from the projection a of the corona in the direction of the light, determines the point b therein, wherefrom the horizontal line intercepted by the line ab in the elevation, also drawn parallel to the direction of the light, gives the point b in the elevation. A line from b, parallel to the inclined sides of the pediment on the left, will give the shadow of the corona on the tympanum on that side, and similarly the line of shadow from b on the right side. cd determines the line of shadow on the frieze, and B is the section of the shadow of the assemblage of mouldings on the right.

2477. In *fig. 853.* is given the plan, elevation, and section of a square recess, covered with a cylindrical head. The lines AA, BB, CC of the elevation are determined by aa, bb, and cc of the plan; and in the section c'c' is the representation of the line cc of the plan. D, the point at which the direction of the light begins to touch the circular head, is d' in the section.

2478. *Fig. 854.* is the elevation of an arch, below which is its plan and the shadow cast by it on the plane upon which it stands. AA is shown by aa on the plan, the corresponding points in the rear of the arch being a' a', and a'' a'' the points in the shadow. In a similar way, by BB corresponding with bb' on the plan the points b'' b'' are obtained in the shadow.

2479. *Fig. 855.* is the plan and elevation of the upper part of a house,

*Fig. 853.*

*Fig. 854.*

wherein the upper story is occupied by an attic in the centre, against which, on each flank, the sloping roof is terminated. *aa* on the plan in the direction of the light, produced to intersect the hip at *b*, gives, by a vertical to *B* on the elevation, the direction *BB* of the shadow thereon; and *BB* cut by *AA* in the direction of the light, the length *BA* of the line of shadow, which may, by letting fall the vertical *Aa*, determine the length *aa* on the plan. The line of shadow *ac* is determined by letting fall a vertical from *C*, where the line of shadow is intercepted by the hip of the roof; and from *c* the shadow will be found on trial to return as shown in the diagram. *E* and *D* on the elevation are found, as seen in previous examples, in *ee*, and *d* on the plan, and their shadows at *e'e'* and *d'*.

FIG. 855.

2480. What is called an attic base is given in plan and elevation by *fig. 856*. The method of obtaining the shadows thereof in plan and elevation is now to be explained. It is an example which constantly occurs in architectural subjects, and should be well studied and understood. The operations requisite for obtaining a representation of the lines of shadow of the different mouldings in this example depend upon the principles developed in the preceding subsections. The lower portion of the figure exhibits the plan, and the middle portion the elevation of the attic base in question. The uppermost portion of it presents three sections of the mouldings of the base in question cut in three different places parallel to the direction of the light. This last portion of the figure is not absolutely necessary, inasmuch as the profiles in question might have been obtained upon the elevation; but we have preferred keeping it separate to prevent a confusion of subsidiary lines. There is moreover another advantage in thus separating the parts from each other, namely, that of immediately and more distinctly seeing the lines at each selected place, in which the rays of light separate the parts actually in light from those in shadow; and where the student is likely to meet with matters of perplexity, nothing should be left untried to save his time, and, what is often more important, his patience. The mode to be adopted is as follows:—

FIG. 856.

Make on the plan any number of sections *a'a'a'a'*, *b'b'b'b'* in the direction of the light, and draw on the elevation the corresponding sections *aaaa*, *bbbb*. *LL* being the direction of the light, draw parallel thereto tangents to the curves of the convex mouldings, and the boundaries of their shades will be obtained, as will also those of their shadows, by continuing them from such boundaries till they cut the other parts in each section, as will be more especially seen at *cc*. It will be recollected that in our first mention of the projected representation of the line of light and shadow we found that it was an angle of  $54^{\circ} 44'$  of the diagonal of a cube. This angle is set out in *xyz* on the plan. We have therefore another mode of finding the boundaries of shade and shadow on the moulding, by developing the sections *a'a'a'a'*, *b'b'b'b'*, &c., as at *A*, *B*, and *C*, and drawing tangents *yz* to the convex mouldings for

boundaries of shade thereon, and continuing them, or otherwise, for the other parts, as shown in the diagram.

2481. In *fig. 857.*, which represents the capital of a column, a similar method is used to that last mentioned for obtaining the shades and shadows, by means of *a'a'a'a'* and *b'b'b'b'*, which are shown on the elevation by *aaaa* and *bbbb*. We apprehend this will be understood by little more than inspection of it.

It is obvious that the means here adopted for obtaining the lines of shadow are precisely similar to those used in the preceding example. In this, however, the sections of the capital parallel to the direction of the light are made on the elevation, and it will be seen that many of them are not required to obtain an accurate boundary of the lines of shadow sought; for after having obtained those points from which the longest shadow falls, and on the other side those where the line of shadow commences, a curve line of an elliptical nature connects the points found. If the drawing to be made be on a large scale, it may then be worth the architect's while to increase the number of points wherefrom the shadow is to be projected, so as to produce the greatest possible accuracy in the representation.

2482. The shadows of an Ionic capital are given in *fig. 858.* The shadow of the volute on the column is obtained by any number of lines *AA*, *BB*, *CC*, &c. from its different

Fig. 857.

Fig. 858.

parts and verticals from their corresponding ones *aa*, *bb*, *cc*, &c. on the plan, and similarly the shadow of the capital on the wall. In this example, as in those immediately preceding, the employment of sectional lines parallel to the direction of the light is again manifest. The use of them is most especially seen in the example of the Corinthian capital which follows. As a general rule, it may be hinted to the student of sciography, that in the difficulties that may occur, they will be most expeditiously and clearly resolved by the use of the sectional lines, whereon we have thought it proper so much to dilate.

2483. The Corinthian capital in *fig. 859.* will require little more than inspection to understand the construction of its sciography; and all that we think necessary to particularise are the developed projections *A*, *B*, *C*, *D*, *E*, *F* of the abacus and the leaves, whereon the termination of the shadows at angles of  $54^{\circ} 44'$ , as explained in *fig. 856.*, give their respective depths on the elevation.

There is another method of arriving at the result here exhibited, by drawing sectional lines parallel to the direction of the light through the different parts and leaves of the

Fig. 859.

capital on its elevation, as in *fig. 857.*, and such was the mode we were formerly in the habit of adopting. It however induces such a confusion of lines, that we have long since abandoned it, and have no hesitation in recommending the process here given as the best and most likely to avoid confusion. It is of course unnecessary, in making drawings, to project more than the shadow of one capital, as in a portico, or elsewhere, similar capitals, similarly exposed to the light, will project similar shadows, so that the projection on one serves for the projection on all of them.

2484. For instruction upon the mode in which reflected light acts upon objects in shade and shadow, we must refer the learner to the contemplation of similar objects in relief. The varieties of reflexes are almost infinite; and though general rules might be laid down, they would necessarily be so complicated, that they would rather puzzle than instruct, and under this head we recommend the study of nature, which will be found the best instructress the student can procure.

#### SECT. IV.

##### WORKING DRAWINGS.

2485. Working drawings are those made of the parts at large for executing the works, which could not be well done from drawings on a small scale, wherein the small parts would not be either sufficiently defined, or could not be figured so as to enable the workman to set out his work with accuracy. They are generally in outline, except the sectional parts, which are frequently hatched or shaded to bring the profiles more readily before the eye.

2486. It is obvious that though drawings made to a twelfth or a twenty-fourth part of their real size may well enough supply the wants of the workman where there is no complication in the distribution and arrangement, and in cases where there is a simple treatment of regular forms, of right angles and the like; yet in all cases wherein we have to deal with the minor details of architecture, and in construction, where the variety of forms used is infinite from the variety of the circumstances, nothing short of drawings of the full or at the least of half the size will safely guide the workman.

2487. The art of making working drawings, which must have been well understood at all periods of the practice of architecture, involves a thorough knowledge of projection, or descriptive geometry, and consists in expressing by lines all that occurs for the development of every part of the details of a building, in plan, elevation, and profile, each part

being placed for the use of the workman with clearness and precision. All the rules by which working drawings are wrought are dependent on the matter in this work already communicated to the reader, excepting only those details of the orders, and some other matters, which will be found in Book III. But we shall here, nevertheless, briefly replace before him the leading principles whereon working drawings are to be prepared. And first, he is to recollect that solids are only represented by the faces opposite to the eye; secondly, that the surfaces by which solids are enclosed are of two sorts, that is, rectilinear or curvilinear. Those bodies in which these properties are combined may be divided into three sorts: 1. Those which are bounded by plane surfaces, such as prisms, pyramids, and generally all straight work. 2. Those in which there is a mixture of straight and curved lines, as cylinders, cones, or portions of them, voussoirs of vaulting, and the like; and 3. Those solids wherein a double flexure occurs, as in the sphere, spheroid, and in many cases of voussoirs.

2488. We should, however, unnecessarily use the space allotted to us by further entering on these matters, on which enough has been already said in previous sections. The plain truth is, that working drawings are to be so made for the use of the artificer as to embody on a scale, by which no mistake ought to occur, all the information which this work has already given on construction, and that which follows in the more refined view of architecture as a fine art.

2489. In works whose magnitude is not of the first class, the drawing of every part, both in construction and in those which involve the work as one of art, every portion should be given of the full size whereof it is proposed to be executed. Where the building is large, as also the parts, this may be dispensed with; but then it becomes (the detail being drawn on a smaller but fully intelligible scale) the duty of the architect to see that the drawings he furnishes are faithfully drawn out to the full size by the artificer on proper moulds. Often it is useful, never, indeed, otherwise, to *offer up*, as it is called, small portions of mouldings on the different parts of a building, to ascertain what the effect may be likely to be at the heights fixed for their real places. In these matters he should leave no means untried to satisfy himself of the effect which what he has first planned *in small* is likely to produce when executed.

2490. We have presumed that the architect is so far educated as to have acquired a full knowledge of all that rules can teach, and that, strictly speaking, he has proportioned his work in conformity with them. Still, in real practice, there are constantly so many circumstances which concur in making it almost necessary to depart from established rules, such as surrounding buildings, where it is of importance to give predominance to a part for the purpose of making it a feature, that the expedient of trying a portion of the proposed detail in the place it is actually to occupy, is a matter that we would advise every architect to adopt after he has made and studied the working drawings whereof we treat.

2491. We have not alluded to the matters of carpentry and joinery, in which it is often necessary to give the artificer information by means of working drawings; but the methods of trussing in carpentry, and of framing in joinery, often require working drawings. What has already been exhibited under those heads (2031, *et seq.*) will prevent his being left uninstructed, and will, moreover, have afforded such information as to prepare him, by the exercise of his own ingenuity, for such cases as may not have been specially given in the examples herein contained. We therefore here close our observations under this section by an intimation to the student, that the proper preparation of working drawings for the use of the artificer tests his acquaintance with the theory and practice of the art, and is of the utmost importance to the pocket of the employer from whom he receives a commission, whereof it is his duty as a gentleman never to lose sight.

## BOOK III.

## PRACTICE OF ARCHITECTURE.

## CHAP. I.

## THE PRINCIPAL PARTS OF A BUILDING.

## SECT. I.

## BEAUTY IN ARCHITECTURE.

2492. THE existence of architecture as a fine art is dependent on *expression*, or the faculty of representing, by means of lines, words, or other media, the inventions which the architect conceives suitable to the end proposed. That *end* is twofold; to be useful, and to connect the use with a pleasurable sensation in the spectator of the invention. In eloquence and poetry the end is to instruct, and such is the object of the higher and historical classes of painting; but architecture, though the elder of the arts, cannot claim the rank due to painting and poetry, albeit its end is so much more useful and necessary to mankind. In the sciences the end is utility and instruction, but in them the latter is not of that high moral importance, however useful, which allows them for a moment to come into competition with the great arts of painting, poetry, and eloquence. It will be seen that we here make no allusion to the lower branches of portrait and landscape painting, but to that great moral and religious end which fired the mind of Michael Angelo in the Sistine Chapel, and of Raffaele Sanzio in the Stanze of the Vatican and in the Cartoons. Above the lower branches of painting just mentioned, the art whereof we treat occupies an exalted station. In it though the chief end is to produce an useful result, yet the expression on which it depends, in common with the other great arts, brings each within the scope of those laws which govern generally the fine arts whose object is beauty. Beauty, whatever difference of opinion may exist on the means necessary to produce it, is by all admitted to be the result of every perfection whereof an object is susceptible, such perfections being altogether dependent on the agreeable proportions subsistent between the several parts, and those between the several parts and the whole. The power or faculty of inventing is called *genius*. By it the mind is capable of conceiving and of expressing its conceptions. *Taste*, which is capable of being acquired, is the natural sensation of a mind refined by art. It guides genius in discerning, embracing, and producing beauty. Here we may for a moment pause to inquire what may be considered a standard of taste, and that cannot be better done than in the words used on the subject by Hume (Essay xxiii.): "The great variety of tastes," says that author, "as well as of opinion, which prevails in the world, is too obvious not to have fallen under every one's observation. Men of the most confined knowledge are able to remark a difference of taste in the narrow circle of their acquaintance, even where the persons have been educated under the same government and have early imbibed the same prejudices. But those who can enlarge their view to contemplate distant nations and remote ages are still more surprised at the great inconsistency and contrariety. We are apt to call *barbarous* whatever departs widely from our own taste and apprehension, but soon find the epithet of reproach retorted on us, and the highest arrogance and self-conceit is at last startled on observing an equal assurance on all sides, and scruples, amidst such a contest of sentiment, to pronounce positively in its own favour." True as are the observations of this philosopher in respect of a standard of taste, we shall nevertheless attempt to guide the reader to some notion of a standard of taste in architecture.

2493. There has lately grown into use in the arts a silly pedantic term under the name of *Æsthetics*, founded on the Greek word *ἁισθητικὸς*, one which means having the power of perception by means of the senses; said to be the science whereby the first principles in all the arts are derived, from the effect which certain combinations have on the mind as connected with nature and reason: it is, however, one of the metaphysical and useless additions

to nomenclature in the arts, in which the German writers abound, and in its application to architecture of least value; because in that art form is from construction so limited by necessity, that sentiment can scarcely be said to be further connected with the art than is necessary for keeping the subordinate parts of the same character as the greater ones under which they are combined; and, further, for thereby avoiding incongruities.

2494. It is well known that all art in relation to nature is subject to those laws by which nature herself is governed, and if we were certain that those rules of art which resulted from reason were necessarily and actually connected with sensation, there would be no difficulty in framing a code of laws whereon the principles of any art might be firmly founded. "Principles in art," as well defined by Payne Knight, "are no other than the trains of ideas which arise in the mind of the artist out of a just and adequate consideration of all those local, temporary, or accidental circumstances upon which their propriety or impropriety, their congruity or incongruity, wholly depend." By way of illustrating the observation just made, we will merely allude to that maxim in architecture which inculcates the propriety of placing openings over openings and piers over piers, disallowing, in other words, the placing a pier over an opening without the exhibition of such preparation below as shall satisfy the mind that security has been consulted. There can be no doubt that a departure from the maxim creates an unpleasant sensation in the mind, which would seem to be immediately and intimately connected with the laws of reason; but there is great difficulty in satisfying one's self of the precise manner in which this operates on the mind, without a recurrence to the primitive types in architecture, and thence pursuing the inquiry. But in the other arts the types are found in nature herself, and hence in them no difficulty occurs in the establishment of laws, because we have that same nature whereto reference may be made. We shall have to return to this subject in the section on the Orders of Architecture, to which we must refer the reader, instead of pursuing the subject here.

2495. Throughout nature beauty seems to follow the adoption of forms suitable to the expression of the end. In the human form there is no part, considered in respect to the end for which it was formed by the great Creator, that in the eye of the artist, or rather, in this case the better judge, the anatomist, is not admirably calculated for the function it has to discharge; and without the accurate representation of those parts in discharge of their several functions, no artist by means of mere expression, in the ordinary meaning of that word, can hope for celebrity. This arises from an inadequate representation having the appearance of incompetency to discharge the given functions; or, in other words, they appear unfit to answer the end.

2496. We are thus led to the consideration of *fitness*, which, after all, will be found to be the basis of all *proportion*, if not *proportion* itself. Alison, in his *Essay on Taste*, says, "I apprehend that the beauty of proportion in forms is to be ascribed to this cause," (*fitness*) "and that certain proportions affect us with the emotion of beauty, not from any original capacity in such qualities to excite this emotion, but from their being expressive to us of the fitness of the parts to the end designed." Hogarth, who well understood the subject, concurs with Alison in considering that the emotion of pleasure which proportion affords does not resemble the pleasure of sensation, but rather that feeling of satisfaction arising from means properly adapted to their end. In his *Analysis of Beauty* that great painter places the question in its best and truest light, when, speaking of chairs and tables, or other common objects of furniture, he considers them merely as fitted from their proportions to the end they have to serve. In the same manner, says Alison, "the effect of disproportion seems to me to bear no resemblance to that immediate painful sensation which we feel from any disagreeable sound or smell, but to resemble that kind of dissatisfaction which we feel when means are unfitted to their end. Thus the disproportion of a chair or table does not affect us with a simple sensation of pain, but with a very observable emotion of dissatisfaction or discontent, from the unsuitableness of their construction for the purposes the objects are intended to serve. Of the truth of this every man must judge from his own experience." We cannot refrain from continuing our extracts from this most intelligent author. "The habit," he says, "which we have in a great many familiar cases of immediately conceiving this fitness from the mere appearance of the form, leads us to imagine, as it is expressed in common language, that we determine proportion by the eye, and this quality of fitness is so immediately expressed by the material form, that we are sensible of little difference between such judgments and a mere determination of sense; yet every man must have observed that in those cases where either the object is not familiar to us or the construction intricate our judgment is by no means speedy, and that we never discover the proportion until we previously discover the principle of the machine or the means by which the end is produced."

2497. The nature of the terms in which we converse shows the dependence of proportion on fitness, for it is the sign of the quality. The natural answer of a person asked why the proportion of any building or machine pleased him, would be, because the object by such proportion was fit or proper for its end. Indeed, proportion is but a synonyme of fitness,

for if the form be well contrived, and the several parts be properly adjusted to their end, we immediately express our opinion that it is well proportioned.

2498. There is, however, between proportion and fitness, a distinction drawn by our author, which must be noticed. "Fitness expresses the relation of the whole of the means to the end; proportion, the proper relation of a part or parts to their end." But the distinction is too refined to be of importance in our consideration; for the due proportion of parts is simply that particular form and dimension which from experience has been found best suited to the object in view. "Proportion," therefore continues Alison, "is to be considered as applicable only to forms composed of parts, and to express the relation of propriety between any part or parts and the end they are destined to serve."

2499. Forms are susceptible of many divisions, and consequently proportions; but these are only subordinate to the great end of the whole. Thus, for instance, in the constantly varying forms of fashion, say in a chair or table, the merely ornamental parts may bear no relation to the general fitness of the form, but they must be so contrived as to avoid unpleasant sensation, and not to interfere with the general fitness. If we do not understand the nature of its fitness, we cannot judge of the proportion properly. "No man," says Alison, "ever presumes to speak of the proportions of a machine of the use of which he is ignorant." When, however, we become acquainted with the use or purpose of a particular class of forms, we at the same time acquire a knowledge which brings under our view and acquaintance a larger circle of agreeable proportions than the rest of the world understand; and those parts which by others are regarded with indifference, we contemplate with pleasure, from our superior knowledge of their fitness for the end designed. The proportions of an object must not in strength be carried beyond what is required for fitness, for in that case they will degenerate into clumsiness, whilst elegance, on the contrary, is the result of the nicest adjustment of proportion.

2500. Fitness cannot exist in any architectural object without *equilibrium* in all the parts as well as the whole. The most complete and perfect notion that can be conceived of *stability*, which is the result of equilibrium, may be derived from the contemplation of an horizontal straight line; whilst, on the contrary, of instability nothing seems more expressive than a vertical straight line. These being, then, assumed as the extremes of stability and instability, by carrying out the gradations between the two extremes, we may, extending in two parts the vertical line, obtain various forms, more or less expressive of stability as they approach or recede from the horizontal line. In *fig. 860*. we have, standing on the same base, the general form of the lofty Gothic spire; the pleasing, solid, and enduring form of the Egyptian pyramid; and that of the flat Grecian pediment: which last, though in its inclination adjusted on different grounds, which have been examined in Book II. Chap. III. subsect. 2027, *et seq.*, is an eminent instance of stability. The spire, from its height and small base, seems to possess but a tottering equilibrium compared with the others.

Fig. 860.

2501. Stability is obviously dependent on the laws of gravitation, on which, under the division of statics, not only the architect, but the painter and sculptor, should bestow considerable attention. We cannot for a moment suppose it will be disputed that at least one of the causes of the beauty of the pyramid is a satisfactory impression on the mind of the state of rest or stability it possesses. Rest, repose, stability, balance, all meaning nearly the same thing, are then the very essential ingredients in fitness; and therefore, in architectural subjects, instability, or the appearance of it, is fatal to beauty. Illustrations of this exist in the famous Asinelli and Garisendi towers at Bologna, and at Pisa in the celebrated leaning Campanile.

2502. It may be objected to what we have written, that fitness alone will not account for the pleasure which arises in the contemplation of what are called the orders of architecture, and Alison seems very much to doubt whether there be not some other cause of beauty. It will, however, be our business to show how the ancients, their inventors, considered principally their fitness; and upon these grounds to show, moreover, how the proportions in ancient examples varied, and may be still further varied, without infringing upon the principles which guided them in the original invention. Payne Knight has well observed, "that the fundamental error of imitators in all the arts is, that they servilely copy the effects which they see produced, instead of supplying and adopting the principles which guided the original artists in producing them; wherefore they disregard all those local, temporary, or accidental circumstances upon which their propriety or impropriety, their congruity or incongruity, wholly depend." "Grecian temples, Gothic abbeys, and feudal castles were all well adapted to their respective uses, circumstances, and situations; the distribution of the parts subservient to the purposes of the whole; and the ornaments and decorations suited to the character of the parts, and to the manners, habits, and employments of the persons who were to occupy them: but the house of an English noble-

man of the 18th or 19th century is neither a Grecian temple, a Gothic abbey, nor a feudal castle; and if the style of distribution or decoration of either be employed in it, such changes and modifications should be admitted as may adapt it to existing circumstances, otherwise the scale of its exactitude becomes that of its incongruity, and the deviation from principle proportioned to the fidelity of imitation." This is but another application of the principle of fitness which we have above considered, the chief foundation of beauty in the art. We have shown how it is dependent on stability as a main source of fitness, and here subjoin some maxims which will lead the student to fitness in his designs, and prevent him from running astray, if he but bring himself to the belief that they are reasonable, and founded upon incontestable grounds, which we can assure him they are.

First. Let that which is the stronger part always bear the weaker.

Second. Let solidity be always real, and not brought to appear so by artifice.

Third. Let nothing be introduced into a composition whose presence is not justified by necessity.

Fourth. Let unity and variety be so used as not to destroy each other.

Fifth. Let nothing be introduced that is not subordinate to the whole.

Sixth. Let symmetry and regularity so reign as to combine with order and solidity.

Seventh. Let the proportions be of the simplest sort.

Eighth. Let him recollect that nothing is beautiful which has not some good and useful end.

If, after having made his design, he will scrupulously test it by these maxims *seriatim*, and will strike out what is discordant with the tenor of them, he will have overcome a few of the difficulties which attend the commencement of his career.

2503. We are not of the same opinion with those who, on a geometrical elevation of a building, draw lines from its apex, which, bounding the principal parts of the outline, find a pyramidal form, and thence infer beauty of general outline. If those who favour such a notion will but reflect for a moment, they must see that this cannot be a test of its effect, inasmuch as the construction of a geometrical elevation of any edifice supposes it to be viewed at an infinite distance, whereas, in fact, it is most generally viewed under angles which would puzzle the most learned architect, without full investigation, to discover the primary lines which they assume to be the causes of its beauty. The obscurations and foreshortenings that take place are at points of view near the building itself; and, however judicious it may be to form the general masses in obedience to such a system, so as to produce an effect in the distance that may be in accordance with the principle, it would be extremely dangerous to lay the principle down as a law. The finest view of St. Paul's is perhaps a little east of Fetter Lane, on the northern side of Fleet Street; but it would puzzle any one to discover its pyramidal form from that point of view.

2504. The beauty of the proportions of architecture in the interiors of buildings is dependent on those which govern the exteriors. Much has been said on proportions of rooms, which, hereafter, we shall have to notice: we mean the proportions of their length to their breadth and height. That these are important, we cannot deny; but whether the beauty of a room is altogether dependent on the due adjustment of these, we have some doubts; that is, under certain limits. We here address ourselves more particularly to that fitness which, in ornamenting a ceiling, for example, requires that the beams which appear below the general surface should invariably fall over piers, and that in this respect corresponding sides should be uniform. In the study of this point, Inigo Jones is the great English master who has left the student the most valuable examples of this branch of the art.

2505. It may, perhaps, be useful to observe generally that the bare proportions of the interiors of apartments depend on the purposes for which they are intended, and according to these we seek immediately for the expression of their fitness. This point, therefore, involves on the part of the architect so general an acquaintance with the most refined habits of his employers, that we should be almost inclined to agree with Vitruvius on the multifarious qualifications necessary to constitute a good one. Certain it is that no instructions he can receive for building a mansion will qualify him without an intimate acquaintance with the habits of the upper classes of society.

2506. We have already stated that it is hopeless to arrive at a fixed standard of taste. That considered worthy of the appellation will not be so considered in another. "The sable Africans," says Knight, quoting from Mungo Park, "view with pity and contempt the marked deformity of the Europeans, whose mouths are compressed, their noses pinched, their cheeks shrunk, their hair rendered lank and flimsy, their bodies lengthened and emaciated, and their skins unnaturally bleached by shade and seclusion, and the baneful influence of a humid climate." In the countries of Europe, where some similarity of taste may be expected, the tyranny of fashion, no less than that of habit and circumstance, has, and always will have, its influence on the arts. Within the short space of even a few months we have seen what is called the *renaissance* style of architecture imported from France, drawing into its vortex all classes of persons, many of them among the higher

ranks, possessed of education to have patronised better taste; and in architecture, and some other arts, no one solves the question of what is really right by saying that there have been errors in the tastes of different ages.

2507. The specimens of Greek sculpture, whose beauty is founded in nature herself, will throughout all time excite the admiration of the world; because in this case, the standard or type being nature, mankind generally may be supposed to be competent judges of the productions of the art. But it is very different in architecture, whose types in every style are, as respects their origin, uncertain; and when we are asked whether there be a real and permanent principle of beauty in the art, though we must immediately reply in the affirmative, we are at the same time constrained to refer it to the quality of fitness. If this were not the case, how could we extend our admiration to the various styles of Egyptian, Grecian, Roman, Gothic, and Italian architecture? These at first appear, compared with each other, so dissimilar, that it seems impossible to assign beauty to one without denying it to the rest. But on examination each will be found so fitted to its end, that such cause alone will be found to be the principal source of the pleasure that an educated mind receives from each style; and that thence it arises, rather than from any certain or definable combinations of forms, lines, or colours that are in themselves gratifying to the mind or agreeable to the organs of sensation. If this be true, what becomes of the doctrine of the German æsthetical school, so vaunted of by self-constituted critics and reviewers, who pass their judgment *ex cathedra* on works they have never seen, and, strange to say, are tolerated for a moment by the public? The truth is, the public rarely give themselves the trouble to judge; and unless led, which is easily done by the few, do not undertake the trouble of judging for themselves. That the Egyptian pyramid, the Grecian and the Roman temple, the early Christian basilica, the Gothic cathedral, the Florentine palace, the Saracenic mosque, the pagoda of the East, are all beautiful objects, we apprehend none will dispute; but there is in none of them a common form or standard by which we can judge of their beauty: the only standard on which we can fall back is the great fitness of them, under their several circumstances, for the end proposed in their erection.

2508. We are thus unavoidably driven to the conclusion that beauty in its application to architecture changes the meaning of the word with every change of its application; for those forms which in one style are strictly beautiful on account of their fitness, applied to another become disgusting and absurd. By way of illustrating this, let us only picture to ourselves a frieze of Grecian triglyphs separating the nave and clerestory of a Gothic cathedral. From what we have been taught to consider the type of the Doric frieze connected with its triglyphs an idea of fitness immediately arises in the mind; but we cannot trace its fitness in a dissimilar situation, neither can we comment on such an incongruity better than in the oft-quoted lines of Horace:—

“ Humano capiti cervicem pictor equinam  
Jungere si velit, et varias inducere plumas  
Undique collatis membris, ut turpius atrum  
Desinet in pisces mulier formosa superne;  
Spectatum admissi risum teneatis amici ? ”

The influence of circumstances in every age has imparted to each style of architecture its peculiar beauty and interest; and until some extraordinary convulsion in society give the impetus to a new one, we are constrained to follow systems which deprive us of other novelty than those of changes which are within the spirit of the universally established laws of the art. Turn to the Gothic churches of the present day.—the little pets of the church commissioners and clergy. What objects of ineffable contempt the best of them are! The fact is, the religious circumstances of the country have so changed that they are wholly unsuitable in style to the Protestant worship. Had, with the scanty means afforded to the architects, such a model as St. Paul's, Covent Garden, been adopted, we might have seen a number of edifices in the country, though

“ Facies non omnibus una  
Nec diversa tamen,”

that might have been an honour to the age in which we live, and suitable to the circumstances of the times.

2509. Unity and harmony in a work necessarily enter into that which is beautiful; and it will not therefore require any argument to show that from a mixture of styles in any building incongruity and unfitness, and consequently a want of unity and harmony, must be the result. Hence we cannot agree with those wise reviewers who advocate the possibility of amalgamating the arch with the severe Grecian style. We leave them to their dreams, and trust that before we give them credence we may have some proof of their practical power in this respect.

2510. Symmetry is that quality which, as its name imports, from one part of an assemblage of parts enables us to arrive at a knowledge of the whole. It is a subordinate, but nevertheless a necessary, ingredient in beauty. It is necessary that parts performing the same office in a building should be strictly similar, or they would not *ex vi termini* be

symmetrical ; so, when relations are strictly established between certain parts, making one the measure of another, a disregard of the symmetry thus induced cannot fail of destroying beauty. But here again we have to say, that for want of attention to the similarity of the parts, or neglect of the established relations on which the whole is founded, they have lost their symmetry, and have thus become *unfit* for their purpose ; so that thus again we return to fitness as the main foundation of beauty.

2511. Colour abstractedly considered has little to do with architectural beauty, which is founded, as is sculpture, on fine form. We are here speaking generally, and are not inclined to assert that the colour of a building in a landscape is unimportant to the general effect of that landscape, or that the colours used on the walls of the interior of a building are unessential considerations ; but we do not hesitate to say that they are of minor consequence in relation to our art. We believe it would be difficult to paint (we mean not in the sense of the artist) the interior of the banqueting room at Whitehall, were it restored to its original destination, and divested of the ruinous accessories which from its original purpose have turned it from a banqueting room into a chapel,—we believe, we say, that it would be difficult to paint it so as to destroy its internal beauty. But as we intend to be short under this head, we shall quote a brochure touching on this subject published by us in 1837.

2512. One of the beauties tending to give effect to the edifices of Greece has been, on the testimony of almost all travellers, the colour of the materials whereof they are composed. Dr. Clarke observes that a warm ochreous tint is diffused over all the buildings of the Acropolis, which he says is peculiar to the ruins of Athens. “Perhaps,” says the author, “to this warm colour, so remarkably characterising the remains of ancient buildings at Athens, Plutarch alluded” (*In Vita Periclis*) “in that beautiful passage cited by Chandler, where he affirmed that the structures of Pericles possessed a peculiar and unparalleled excellence of character ; a certain freshness bloomed upon them and preserved their faces uninjured, as if they possessed a never-fading spirit, and had a soul insensible to age.” It is singular that recent discoveries have incontestably proved that this species of beauty at all events did not originally exist in them, inasmuch as it is now clearly ascertained that it was the practice of the Greeks to paint the whole of the inside and outside of their temples in party colours. It had been some time known that they were in the habit of painting and picking out the ornaments on particular parts of their buildings ; but M. Schaubert, the architect of the King of Greece, found on examination that this fell far short of the extent to which this species of painting was carried, and M. Semper, another German architect, has fully corroborated the fact in his examination of the Temple of Theseus. The practice was doubtless imported into Greece from Egypt, and was not to be easily abandoned, seeing the difficulty of falling away from the habits of a people whence it seems certain the arts of Greece more immediately came. It is by no means uncommon for a person to be fully alive to all the beauties of form, without at the same time having a due feeling or perception of the beauty resulting from harmony in colouring. It is therefore not to be assumed that the Greeks, though given to a practice which we would now discourage, possessed not that taste in other respects which has worthily received the admiration of posterity. The practice of painting the inside and outside of buildings has received the name of *polychromatic* architecture, and we shall here leave it to the consideration of the student as a curious and interesting circumstance, but certainly without a belief that it could add a charm to the stupendous simplicity and beauty of such a building as the Parthenon.

2513. After all that we have said of fitness, it will be expected that in *decoration* it shall form a principal ingredient. By the term decoration we understand the combination of objects and ornaments that the necessity of variety introduces under various forms, to embellish, to enrich, and to explain the subjects whereon they are employed. The art of decoration, so as to add to the beauty of an object, is, in other words, that of carrying out the emotions already produced by the general form and parts of the object itself. By its means the several relations of the whole and the parts to each other are increased by new combinations ; new images are presented to the mind whose effect is variety, one great source of pleasure. From these observations two general rules may be deduced in respect of decoration. *First*, that it must actually be or seem to be necessary. *Second*, that such objects must be employed in it as have relation to the end of the general object of the design. We are not to suppose that all parts of a work are susceptible of ornament. Taste must be our guide in ascertaining where decoration is wanted, as well as the quantity requisite. The absence of it altogether is in many cases a mode of decoration. As in language its richness and the luxuriance of images do not suit all subjects, and simplicity in such cases is the best dress, so in the arts of design many subjects would be rather impoverished than enriched by decoration. We must therefore take into consideration the character of the building to be decorated, and then only apply such ornament as is necessary and suitable to that character. We may judge of its necessity if the absence of it causes a dissatisfaction from the void space left ; of its suitableness, by its developing the character. History has recorded the contempt with which that decorator was treated who

ornamented the senate house with statues of wrestlers, and the gymnasium with statues of senators.

2514. By some the art of architecture itself has been considered nothing more than that of decorating the buildings which protection from the elements induces us to raise.

2515. The objects which architecture admits for decoration result from the desire of producing *variety, analogy, and allegory*. We here follow Quatremère de Quincy. (*Encyc. Method.*) The first seems more general than the others, as being common among all nations that practise building. It is from this source we have such a multitude of cut-work, embroidery, details, compartments, and colours, more or less minute, which are found in every species of architecture. It would be useless for the most philosophical mind to seek for the origin of these objects in any want arising out of the mere construction, or in any political or superstitious custom. Systems of conjecture might be exhausted without arriving one point nearer the truth. Even in the most systematic of the different kinds of architecture, namely, that of the Greeks, we cannot avoid perceiving a great number of forms and details whose origin is derived from the love of variety, and that alone. In a certain point of view, thus considered, an edifice is nothing more than a piece of furniture, a vase, an utensil, the ornaments on which are placed more for the purpose of pleasing the eye than any other. Such, for instance, are the roses of caissons in ceilings and soffites, the leaves round the bell of the Corinthian capital, the Ionic volutes, and many others, besides universally the carving of mouldings themselves. These ornaments, drawn from the store-house of nature, are on that account in themselves beautiful; but it is their transference to architecture, which in the nature of things can have but a problematical and conjectural origin, that seems to indicate a desire to vary the surface. Unless it was the desire of variety that induced them, we know not what could have done so.

2516. It has been well observed by the author we have just quoted, that though the art has been obliged to acknowledge that many of its decorations depend in their application on such forms as necessity imposes, and in the formation of them on chance, caprice, or whatever the love of variety may dictate, yet in the disposition of them there must reign an order and arrangement subordinate to that caprice, and that at this point commences the difference between architecture as an art subservient to laws which are merely dependent on the pleasure imparted to the eye, and those which depend on the mere mechanical disposition of the building considered as a piece of furniture. Architecture, of all the arts, is that which produces the fewest emotions of the minds of the many, because it is the least comprehensible in regard to the causes of its beauty. Its images act indirectly on our senses, and the impressions it seems to make appear reducible chiefly to magnitude, harmony, and variety, which after all are not qualities out of the reach of an architect of the most ordinary mind, and therefore not—at least the first and last—unattainable where economy does not interfere to prevent the result to be attained.

2517. Analogy, the second of the objects by which decoration is admitted into architecture, seems to be resultant from the limited nature of all human inventions in the arts, and the power of being unable to invent except by imitation and alteration of the forms of objects pre-existent. It is most difficult to discard altogether what have been considered types in architecture, and that difficulty has so prevailed as to limit those types to their most probable origin in the case of the orders.

2518. The reader will begin to perceive that our analogy in decoration tends upon trees for columns, the ends of beams for triglyphs, and the like. Whatever truth there may be in this analogy, it is now so established as to guide the rules of decoration that are involved in it; and it must be conceded, that if we are desirous of imitating the peculiar art of any country, we have no hope of success but by following the forms which the construction in such country engenders; and we must admit that, as far as external circumstances can direct us, the architecture of Greece, which, modified, has become that of the whole of Europe, and will become that of America, seems so founded on the nature of things, that, however we may doubt, it would not be prudent to lead the reader away from the consideration, and perhaps from a belief, that such is the truth. Without holding ourselves bound by the analogy of the types of the tree and the cross beam, which appear to have guided the architects of Greece, we can without hesitation assert, that whenever those have been abandoned the art has fallen on the most flagrant vices; witness the horrors of the school of Borromini, where the beams are broken, pediments, which are the gables of roofs, are broken into fantastic forms, and none of the parts seem naturally connected with each other. The works of the school in question seem indeed so broken up, that the study of them would almost convince an impartial and competent judge that the converse of its practice is sufficiently beautiful to establish the truth of the types whereon we have here and before expressed our scepticism. “*Sitôt,*” says De Quincy, “*que le génie décorateur s’est cru libre des entraves de l’analogie, toutes les formes caractéristiques se sont contournées, perverties, et dénaturées, au point qu’il y a entr’elles et celle de la bonne architecture, plus de distance qu’entre celles-ci et les types de la primitive construction.*”

2519. In the decoration of architecture, neither of the other two means employed are

more important than that ocular language which architecture occasionally employs in its ornaments. By its use architecture is almost converted into painting, and an edifice becomes a picture, or a collection of pictures, through the aid of the sculptor. We shall refer to no other building than the Parthenon to prove the assertion. Here the history of the goddess is embodied in the forms of the building, and to the decoration thus introduced the subordinate parts of the sculpture, if it be not heresy so to call them, is kept so under that we are almost inclined to cry out against their not having been principals instead of accessories. This is the true principle upon which buildings should be decorated to impress the mind of the spectator with the notion of beauty, and the principle which, carried out, no matter what the style be, will insure the architect his most ample reward, reputation. The matter that is supplied by allegory for decoration in architecture may be considered under three heads — *attributes, figures, and paintings.*

2520. The first takes in all those foliages, plants, flowers, and fruits, which from their constant use in sacrifices were at last transferred from the altar to the walls of the temple. The garlands, festoons, chaplets, and crowns which we find sculptured on temples seem to have had their origin from the religious ceremonies performed in them; as do the instruments of sacrifice, vases, the heads of the victims, patera, and all the other objects employed in the worship of the ancients. Thus, in architecture, these have become conventional signs, indicating the destination of the buildings to which they are applied. From the particular application of some ornaments on temples we derive in the end a language in the arts of imitation. It was thus that the eagle grasping in his talons the attribute of Jupiter, came to represent eternity and omnipotence; the myrtle and dove of Venus, the passion of love; the lyre and laurel of Apollo, to point to harmony and glory; the spear and helmet of Mars, to represent war. Palms and crowns became the emblems of victory, as did the olive the emblem of peace. In the same way the ears of corn of Ceres, the serpent of Esculapius, the bird of Minerva, and the cock of Mercury were equivalent to the expression of abundance, science, and vigilance. Instruments of the arts, sciences, in short, all objects useful to the end for which an edifice is erected, naturally become signs of that edifice; but applied otherwise become absurd. What, for instance, could be more ridiculous than placing ox skulls and festoons on the frieze of a Protestant church? — and yet this has been done in our own days.

2521. Figures of men and animals come under the second head. The application of these may be seen to their highest perfection in the Parthenon, to which we have already alluded. They may be introduced in low, high, or full relief. In the last case their situation is usually that of a niche. We shall say no more on the subject of figures than that of course they must have relation to the end for which the edifice is erected, and if not in that respect perfectly intelligible are worse than useless.

2522. The walls of Pompeii furnish ancient examples of the decoration obtained by the aid of painting, as do the loggie of the Vatican and the ceilings of the Farnesina modern examples of it. Herein the moderns have far surpassed anything we know of the ancient application of painting. Sculpture, however, seems more naturally allied to architecture than painting, and, except in purely decorative painting on walls and ceilings, the introduction of it seems bounded within narrow limits. The rules as to fitness of the subjects introduced, applicable to the first two heads, are equally so under that of painting.

## SECT. II.

### THE ORDERS.

2523. An order in architecture is a certain assemblage of parts subject to uniform established proportions, regulated by the office that each part has to perform. It may be compared to what organisation is in animal nature. As from the paw of a lion his dimensions may be deduced, so from a triglyph may be found the other parts of an example of the Doric order, and from given parts in other orders the whole configuration may be found. As the genus may be defined as consisting of *essential* and *subservient* parts, the first-named are the column and its entablature, which, as its name imports, is as it were the tabled work standing on the column. The subservient parts are the mouldings and detail into which the essential parts are subdivided, and which we shall hereafter separately consider. The species of orders are five in number, Tuscan, Doric, Ionic, Corinthian, and Composite, each of whose mass and ornaments are suited to its character and the expression it is intended to possess. These are the five orders of architecture, in the proper understanding and application whereof is laid the foundation of architecture as an art. The characters of strength, grace, and elegance, of lightness and of richness, are distinguishing features of the several orders, in which those characters ought to be found not only in the column employed, but should pervade the whole composition, whereof the

column is, as it were, the regulator. The mode of setting up, or, as it is technically termed, profiling an order, will be given in a subsequent part of this section. Here we shall merely observe that the entablature is subdivided into an architrave, which lies immediately upon the column, a frieze lying on the architrave, and a cornice, which is its uppermost subdivision. The height of these subdivisions together, that is, the whole height of the entablature, is one fourth that of the column according to the practice of the ancients, who in all sorts of entablatures seldom varied from that measure either in excess or defect. "Palladio, Seamozzi, Alberti, Barbaro, Cataneo, Delorme, and others," says Sir William Chambers, "of the modern architects, have made their entablatures much lower in the Ionic, Composite, and Corinthian orders than in the Tuscan or Doric. This, on some occasions, may not only be excusable but highly proper; particularly where the intercolumniations are wide, as in a second or third order, in private houses, or inside decorations, where lightness should be preferred to dignity, and where expense, with every impediment to the convenience of the fabric, are carefully to be avoided; but to set entirely aside a proportion which seems to have had the general approbation of the ancient artists is surely presuming too far."

2524. As rules in the fine arts which have obtained almost universal adoption are founded on nature or on reason, we may be pretty certain that they are not altogether empirical, albeit their origin may not be immediately apparent. The grounds on which such rules are founded will, however, in most cases become known by tracing them to first principles, which we shall here endeavour to do in respect of this very important relation of height between the column and its entablature. We were first led into this investigation by the perusal of a work by M. Lebrun, entitled *Théorie de l'Architecture Grecque et Romaine deduite de l'analyse des Monumens antiques*, fol. Paris, 1807; but our results differ very widely from those of Lebrun, as will be seen on reference to that work.

2525. One of the most obvious principles of proportion in respect of loads and supports, and one seemingly founded on nature herself, is, that a support should not be loaded with a greater mass or load than itself; or, in other words, that there should be an equality between weights and supports, or, in the case in point, between the columns and entablature. In respect of the proportion of the voids below the entablature between the columns or supports, a great diversity of practice seems to have prevailed, inasmuch as we find them varying from 1·03 to 2·18, unity being the measure of the supports. Lebrun makes the areas of the supports, weights, and voids equal to one another, and in what may be termed the monumental examples of the Doric order, such as the Parthenon, &c., he seems borne out in the law he endeavours to establish; but in lighter examples, such as the temple (Ionic) of Bacchus at Teos, where the supports are to the voids as 1 : 2·05, and in the temple of Minerva Polias, where the ratio is as 1 : 2·18, he is beyond all question incorrect: indeed there hardly seems a necessity for the limitation of the voids he prescribes, seeing that, without relation separately to the weight and support, stability would be obtained so long as the centre of gravity of the load fell within the external face of the support. If it be admitted that, as in the two examples above mentioned, the voids should be equal to the supports jointly, we have a key to the rule, and instead of being surprised at the apparently strange law of making the entablature one fourth of the height of the column, we shall find that no other than the result assumed can flow from the investigation.

2526. In fig. 861. let AB be the height of the column, and let the distance between the columns be one third of the height of the column = CD. Now if AB be subdivided into four equal parts at *a*, *b*, and *c*, and the horizontal lines *ad*, *be*, and *cf* be drawn; also, if CD be divided horizontally into four equal parts, and lines be drawn perpendicularly upwards intersecting the former ones, the void will be divided into sixteen equal parallelograms, one half whereof are to be the measure of the two whole supports BC and DE; and DE being then made equal to one half of CD, it will be manifest, from inspection, that the two semi-supports will jointly be equal to eight of the parallelograms above mentioned, or one half of the void. We have now to place the entablature or weight AGHI upon the supports or columns, and equal to them in mass. Set up from A to F another row of parallelograms, each equal to those above mentioned, shown on the figure by AFKI. These will not be equal to the supports by two whole parallelograms, being in number only six instead of eight; dividing, therefore, 8, the number in the supports, by 6, the number already obtained, we have 1·333, &c., which is the height to be assigned to AG, so that the weight may exactly equal the supports, thus exceeding one quarter of the height of the support (or column) by  $\frac{333}{1000}$  of such quarter, a coincidence sufficient to corroborate the reason on which the law is founded.

Fig. 861.

2527. From an inspection of the *figs.* 861, 862, 863, it appears that when the void is one third the height of the supports in width, the supports will be 6 diameters in height; when one fourth of their height, they will be 8 diameters high; also that the intercolumniation, called systylos or of two diameters, is constant by the arrangement. When the surface of the columns, as they appear to the eye, is equal to that of the entablature, and the voids are equal to the sum of those surfaces, the height of the entablature will always be one third of that of the columns. Thus, let the diameter of the columns be = 1, their height =  $h$ , their number =  $n$ . Then the surface of the columns is  $nh$ ; that of the entablature the same. As the surface of the voids is double that of the columns, the width of the intercolumniations is double the width of the columns, that is,  $2n$  diameters, which, added to the  $n$  diameters of the columns, gives  $3n$  diameters for length of the entablature; therefore, the surface of this entablature is  $nh$ , and its length being  $3n$ , its height must be  $\frac{nh}{3n} = \frac{h}{3}$  exactly.

Fig. 862.

Fig. 863.

2528. Trying the principle in another manner, let *fig.* 864. be the general form of a tetrastyle temple wherein the columns are assumed at pleasure 8 diameters in height.

Fig. 864.

Fig. 865.

Then  $4 \times 8 = 32$  the areas of the supports; and as to fulfil the conditions the three voids are equal to twice that area, or 64, they must consequently be in the aggregate equal to 8 diameters, for  $\frac{64}{8} = 8$ , and the whole extent will therefore be equal to 12 diameters of a support or column. To obtain the height of the entablature so that its mass may equal that of the supports, as the measures are in diameters, we have only to divide 32, the columns, by 12, the whole extent of the facade, and we obtain two diameters and two thirds of a diameter for the height of the entablature, making it a little more than one quarter of the height of the column, and again nearly agreeing in terms of the diameter with many of the finest examples of antiquity. If a pediment be added, it is evident, the dotted lines AC, CB being bisected in  $a$  and  $b$  respectively, that the triangles AEd, bFB are respectively equal to CDa and DbC, and the loading or weight will not be changed.

2529. Similar results will be observed in *fig.* 865., where the height is ten diameters, the number of columns 6, the whole therefore 180, the supports being 60. Here  $\frac{60}{9} = 3\frac{1}{3}$  diameters will be the height of the entablature. This view of the law is further borne out by an analysis of the rules laid down by Vitruvius, book iii. chap. 2.; — rules which did not emanate from that author, but were the result of the practice of the time wherein he lived, and, within small fractions, strongly corroborative of the soundness of the hypothesis of the voids being equal to twice the supports. Speaking of the five species of temples, after specifying the different intercolumniations, and recommending the eustylos as the most beautiful, he thus directs the formation of temples with that interval between the columns. "The rule for designing them is as follows:—The extent of the front being given, it is, if tetrastylos, to be divided into  $11\frac{1}{2}$  parts, not including the projections of the base and plinth at each end; if hexastylos, into 18 parts; if octastylos, into  $24\frac{1}{2}$  parts. One of either of these parts, according to the case, whether tetrastylos, hexastylos, or octastylos, will be a measure equal to the diameter of one of the columns." . . . . "The heights of the columns will be  $8\frac{1}{2}$  parts. Thus the intercolumniations and the heights of the columns will have proper proportion." In the same chapter he gives directions for setting out aræostyle, diastyle, and systyle temples, which directions it is not here necessary to investigate, and our limits do not indeed permit us so to do. We

will therefore now examine the directions quoted. The tetrastylus is  $11\frac{1}{2}$  parts wide and  $8\frac{1}{2}$  high; the area therefore of the whole front becomes  $11\frac{1}{2} \times 8\frac{1}{2} = 97\frac{3}{4}$ . The four columns are  $4 \times 8\frac{1}{2} = 34$ , or a very little more than one third of the whole area; the remaining two thirds, speaking in round numbers, being given to the intercolumns or voids.

2530. The hexastylus (see *fig. 865.*) is 18 parts long and  $8\frac{1}{2}$  high; the whole area therefore is  $18 \times 8\frac{1}{2} = 153$ . The six columns will be  $6 \times 8\frac{1}{2} = 51$ , or exactly one third of the whole area; the voids or intercolumns occupying the remaining two thirds.

2531. The octastylus is  $24\frac{1}{2}$  parts in extent and  $8\frac{1}{2}$  in height. Then  $24\frac{1}{2} \times 8\frac{1}{2} = 208\frac{1}{4}$ . The eight columns will be  $8 \times 8\frac{1}{2} = 68$ , being a trifle less than one third of the area, and the voids or intercolumns about double, or the remaining two thirds.

The average of the intercolumns in the first case will be  $\frac{11\frac{1}{2}-4}{3} = 2\frac{1}{2}$  diameters.

In the second case - - - - -  $\frac{18-6}{5} = 2\frac{2}{5}$  diameters.

In the third case - - - - -  $\frac{24\frac{1}{2}-8}{7} = 2\frac{37}{100}$  diameters.

A discrepancy between practice and theory, unless extremely wide, must not be allowed to interfere with principles, and we have therefore no hesitation in candidly submitting a synoptical view of some of the most celebrated examples of antiquity in which a comparison is exhibited between the voids and supports; certain it is that in every case the former exceed the latter, and that in the earlier examples of Doric, the ratio between them nearly approached equality. In comparing, however, the supports with the weights, there is every appearance of that part of the theory being strictly true; for in taking a mean of the six examples of the Doric order, the supports are to the weights as 1 : 1·16; in the five of the Ionic order as 1 : 1·05; and in the four of the Corinthian order as 1 : 1·04, a coincidence so remarkable, that it must be attributed to something more than accident, and deserves much more extended consideration than it has hitherto received.

Building.	Order.	Number of Columns.	Supports.	Weights.	Voids.
Temple of Jupiter Nemeus - -	Doric	6	1·00	0·79	1·03
Parthenon - - - - -		8	1·00	1·07	1·04
Temple at Bassæ - - - - -		6	1·00	1·14	1·16

Temple of Theseus at Athens - -		6	1·00	1·13	1·21
Temple of Jupiter Panhellenius - -		6	1·00	1·45	1·36
Temple of Erectheus - - - - -	Ionic	6	1·00	0·89	1·24
Temple of Fortuna Virilis at Rome -		4	1·00	1·15	1·71
Temple on the Ilyssus - - - - -		4	1·00	0·96	1·72
Temple of Bacchus at Teos - - - -		8	1·00	1·35	2·05
Temple of Minerva Polias, Athens -	Corinthian	4	1·00	1·01	2·18
Portico of Septimius Severus - - -		6	1·00	0·93	1·37
Maison Carrée at Nîmes - - - - -		6	1·00	0·93	1·58
Temple at Jackly - - - - -		6	1·00	0·90	1·62
Pantheon Rome - - - - -	-	8	1·00	1·43	1·84

If instead of taking the apparent bulk of a column, that is, as a square pier, we take its real bulk, which is about three quarters ( $\frac{3}{4}$ ) that of a square pier of the same diameter and height; the height of the entablature will be one fourth of the height of the column; for  $\frac{3}{4}$  of  $\frac{4}{3} = \frac{1}{4}$ .

There is a curious fact connected with the hypothesis which has been suggested that requires notice; it is relative to the area of the points of support for the edifice which the arrangement affords. In *fig. 866.* the hatched squares represent the plans of quarter piers of columns in a series of intercolumniations every way, such intercolumniations being of two diameters, or four semidiameters. These, added to the quarter piers, make six semidiameters, whose square 36 is therefore the area to be covered with the weight. The four quarter piers or columns = 4, hence the points of support are  $\frac{4}{36}$  of the area = 0·111. Now in the list (1583.) of ratio is 0·163, differing only 0·057: the following buildings, the mean

S. Sabino - - - - -	0·100		
S. Filippo Neri - - - - -	0·129	Sum = 0·474.	Mean $\frac{0·474}{4} = 0·118$ .

## MOULDINGS.

2532. The subservient parts of an order, called mouldings, and common to all the orders, are eight in number. They are—1. The *ovolo*, *echinus*, or *quarter round*. (*Fig. 867.*) It is formed by a quadrant, or sometimes more of a circle, but in Grecian examples its section is obtained by portions of an ellipse or some other conic section. This latter observation is

Fig. 867.

Fig. 868.

Fig. 870.

Fig. 871.

Fig. 872.

Fig. 873.

Fig. 874.

applicable to all mouldings of Greek examples, and we shall not repeat it in enumerating the rest of them. It is commonly found under the abacus of capitals. The ovolo is also almost always placed between the corona and dentils in the Corinthian cornice: its form gives it the appearance of seeming fitted to support another member. It should be used only in situations above the level of the eye. 2. The *talon*, *ogee*, or *reversed cyma* (fig. 868.) seems also, like the ovolo, a moulding fit for the support of another. 3. The *cyma*, *cyma recta*, or *cymatium* (fig. 869.) seems well contrived for a covering and to shelter other members. The *cyma recta* is only used properly for crowning members, though in Palladio's Doric, and in other examples, it is found occasionally in the bed mouldings under the corona. 4. The *torus* (fig. 870.), like the astragal presently to be mentioned, is shaped like a rope, and seems intended to bind and strengthen the parts to which it is applied; while, 5. The *scotia* or *trochilos* (fig. 871.), placed between the fillets which always accompany the tori, is usually below the eye; its use being to separate the tori, and to contrast and strengthen the effect of other mouldings as well as to impart variety to the profile of the base. 6. The *cavetto*, *mouth*, or *hollow* (fig. 872.) is chiefly used as a crowning moulding, like the *cyma recta*. In bases and capitals it is never used. By workmen it is frequently called a *casement*. 7. The *astragal* (fig. 873.) is nothing more than a small torus, and, like it, seems applied for the purpose of binding and strengthening. The astragal is also known by the names of *bead* and *baguette*. 8. The *fillet*, *listel*, or *annulet* (fig. 874.) is used at all heights and in all situations. Its chief office is the separation of curved mouldings from one another.

2533. Sir William Chambers observes on these different mouldings that their inventors meant to express something by their different figures, and that the destinations above mentioned "may be deduced not only from their figures, but from the practice of the ancients in their most esteemed works; for if we examine the Pantheon, the three columns in the Campo Vaccino, the temple of Jupiter Tonans, the fragments of the frontispiece of Nero, the basilica of Antoninus, the forum of Nerva, the arches of Titus and Septimius Severus, the theatre of Marcellus, and indeed almost every ancient building, either at Rome or in other parts of Italy and France, it will be found that in all their profiles the *cyma* and *cavetto* are constantly used as finishings, and never applied where strength is required. That the ovolo and talon are always employed as supporters to the essential members of the composition, such as the modillions, dentils, and corona; that the chief use of the torus and astragal is to fortify the tops and bottoms of columns, and sometimes of pedestals; . . . "and that the scotia is employed only to separate the members of bases, for which purpose the fillet is likewise used not only in bases but in all kinds of profiles." It is the fitness of these forms for their ends in their several situations that gives them a positive and natural beauty, which is immediately destroyed by their change of position, as primary forms of architecture; and the author just quoted well observes, "that Palladio erred in employing the cavetto under the corona in three of his orders, and in making such frequent use through all his profiles of the *cyma* as a supporting member. Nor has Vignola been more judicious in finishing his Tuscan cornice with an ovolo; a moulding extremely improper for the purpose, and productive of a very disagreeable effect; for it gives a mutilated air to the whole profile, so much the more striking, as it resembles exactly that half of the Ionic cornice which is under the corona."

2534. The simplest method of describing the contours of mouldings is to form them of

quadrants of circles. Those of the ovolo, talon, cyma, and cavetto being equal to their height, and those of the curve parts of the torus, and astragal equal to half their height. Circumstances, however, often justify a variation from the rule; and if that be the case, the ovolo, talon, cyma, and cavetto may be either described from the summits of equilateral triangles, or be composed of portions of the ellipsis, which latter was almost constantly used by the Greeks. By means of it also the scotia may be produced, as well as by quadrants of circles; but the curved part of the torus and astragal is always semicircular in form, and if more projection is wanted it is obtained by the use of straight lines.

#### ORNAMENTS OF MOULDINGS.

2535. In ornamenting the profile of an order, repose requires that some mouldings should be left plain. If all were enriched, confusion instead of variety would result. Except for particular purposes, the square members are rarely carved. There are but few examples in the best age of the art in which the corona is cut; indeed at this moment the only one that occurs to us wherein work is in fine style is that of the three columns in the Campo Vaccino. So where the ovolo above and talon below it are carved, the dentil band between them should be uncut. Scamozzi, in the third chapter of his sixth book, inculcates that ornaments should be neither profuse nor abundant, neither are they to be too sparingly introduced. Thus they will be approved if applied with judgment and discretion. Above all things, they are to be of the most beautiful forms and of the exactest proportions; ornaments in buildings, being like the jewels used for the decoration of princes and princesses and persons of high rank, must be placed only in proper situations. Neither must variety in ornaments be carried to excess. We have to recollect that, being only accessories, they must not obtrude upon but be kept subordinate to the main object. Thus ornaments applied to mouldings should be simple, uniform, and combining not more than two distinct forms in the same enrichment; and when two forms are used on the same moulding they should be cut equally deep, so that an uninterrupted appearance may be preserved. Mouldings of the same form and size on one and the same profile should be similar; and it is moreover a requisite of the greatest importance, so to distribute the centres of the ornaments employed that the centre of one may fall exactly over the centres of those below, of which the columns of the Campo Vaccino form an example for imitation in this respect. Nothing is more offensive than, for example, to see the middle of an egg placed over the edge of a dentil, and in another part of the same moulding to see them come right, centre over centre, and the like negligent and careless distribution. This may always be avoided by making the larger parts regulate the smaller. Thus where there are modillions they must be made to govern the smaller ornaments above and below them, and these smaller ones should always be subdivided with a view to centring with the larger parts. The larger parts are dependent on the axes of the columns and their intercolumniations; but all these must be considered in profiling the order. It will of course be necessary to give the ornaments such forms as may be consistent with the character of the order they enrich. The enrichment of a frieze depends upon the destination of the building, and the ornaments may have relation to the rank, quality, and achievements of the proprietor. We do not agree with Chambers in condemning the introduction of arms, crests, and cyphers, as an unbecoming vanity in the master of the fabric. These may often be so introduced as to indicate the alliances of the family, and thus give a succinct history of its connections. In Gothic architecture we know the practice induced great beauty and variety. We have before observed, in Sect. I. of this Book (2520.), that the instruments and symbols of pagan worship are highly indecorous, not to say ludicrous, on edifices devoted to the Christian religion.

2536. In carving ornaments they must be cut into the solid, and not carved as if they were applied on the solid, because the latter practice alters their figure and proportion. In fact, every moulding should be first cut with its contour plain, and then carved, the most prominent part of the ornament being the actual surface of the moulding before carving, observing that all external and re-entering angles are kept plain, or have only simple leaves with the central filament expressed on or in the angle. In the circular temple of Tivoli the principle of cutting the ornament out of the solid is carried out so far, that the leaves, as usual in most examples of the Corinthian order, instead of being mere appliquéés to the bell of the capital, are actually cut out of it.

2537. The degree of relief which ornaments ought to have is dependent on their distance from the eye and the character of the composition: these matters will also regulate the degree of finish they ought to possess. There are some mouldings whose profile is indicative of bearing weight, as the ovolo and talon, which by being deeply cut, though themselves heavy in character, are thereby susceptible of having great lightness imparted to them, whilst such as the cyma and cavetto should not be ornamented deep in the solid. The imitation from nature of the objects represented should be carefully observed, the result whereof will impart beauty and interest to the work on which such attention is bestowed.

## CHARACTERS OF THE ORDERS.

2538. In the First Book of this work, Sect. XI. (133, *et seq*) we have considered the history of the five orders of architecture; we shall here offer some general observations upon them before proceeding to the detail of each separately. The orders and their several characters and qualities do not merely appear in the five species of columns into which they have been subdivided, but are distributed throughout the edifices to which they are applied, the column itself being the regulator of the whole composition. It is on this account the name of orders has been applied to the differently formed and ornamented supports, as columns, which have received the names of the Doric, Ionic, Corinthian, Tuscan, and Composite orders, whereof the three first are of Grecian origin, and the two last, it is supposed, of Italian or Roman origin. Each of these, by the nature of its proportions, and the character resulting from them, produces a leading quality, to which its dimensions, form, and ornaments correspond. But neither of the orders is so limited as to be confined within the expression of any single quality. Thus the strength indicated in the Doric order is capable of being modified into many shades and degrees of that quality. We may satisfy ourselves of this in an instant by reference to the early compared with the later Doric column of the Greeks. Thus the columns of the temple at Corinth are only four diameters high, while those of the portico of Philip are six and a half.

2539. As the Doric seems the expression of strength, simplicity, and their various modes, so the Ionic, by the rise in height of its shaft and by the slenderness of its mass, as well as by the elegance of its capital, indicates a quality intermediate between the grave solidity of the Doric and the elegant delicacy of the Corinthian. Bounded on one side by strength, and by elegance on the other, in the two orders just named, the excess of elegance in the Corinthian order ends in luxury and richness, whereof the character is imprinted on it.

2540. We cannot here refrain from giving, in the words of the excellent Sir Henry Wotton, a quaint and homely, but most admirable description of these five orders, from his *Elements of Architecture*. "First, the *Tuscan* is a plain massive rural pillar, resembling some sturdy, well-limbed labourer, homely clad, in which kind of comparisons, Vitruvius himself seemeth to take pleasure." (Lib. iv. cap. 1.) . . . "The *Dorique* order is the gravest that hath been received into civil use, preserving, in comparison of those that follow, a more masculine aspect and little trimmer than the *Tuscan* that went before, save a sober garnishment now and then of lions' heads in the cornice, and of triglyphs and metopes always in the frieze." . . . "To discern him will be a piece rather of good heraldry than of architecture, for he is known by his place when he is in company, and by the peculiar ornament of his frieze, before mentioned, when he is alone." . . . "The *Ionic* order doth represent a kind of feminine slenderness; yet, saith Vitruvius, not like a light housewife, but, in a decent dressing, hath much of the *matrone*." . . . "Best known by his trimmings, for the bodie of this *columnne* is perpetually *chaneled*, like a thick-pleighted gowne. The *capitall* dressed on each side, not much unlike women's wires, in a spiral wreathing, which they call the *Ionian voluta*." . . . "The *Corinthian* is a *columnne* lasciviously decked like a courtesan, and therefore in much participating (as all inventions do) of the place where they were first born, *Corinth* having bene, without controversie, one of the wantonest towns in the world." . . . "In short, as plainness did characterise the *Tuscan*, so, much delicacie and varietie the *Corinthian* pillar, besides the height of his rank." . . . "The last is the compounded order, his name being a briefe of his nature: for this pillar is nothing in effect but a medlie, or an amasse of all the precedent ornaments, making a new kinde by stealth, and though the most richly tricked, yet the poorest in this, that he is a borrower of his beautie." Each of the orders, says De Quincy, is, then, in the building to which it is applied, the governing principle of the forms, taste, and character of that system of moral order met with in Grecian architecture which alone seems to have suited the physical order of proportions with each part, so that what is agreeable, ornate, and rich is equally found in the whole as in the parts.

2541. On the two Latin orders we do not think it necessary to say more than that they will be fully described in following pages. The invention of new orders must arise out of other expressions of those qualities which are already sufficiently well and beautifully expressed; hence we consider, with De Quincy, to attempt such a thing would be vain. Chambers thus expresses himself on this subject, without the philosophy of De Quincy, yet with the feelings of a learned and experienced architect: "The ingenuity of man has, hitherto, not been able to produce a sixth order, though large premiums have been offered, and numerous attempts been made, by men of first-rate talents to accomplish it. Such is the fettered human imagination, such the scanty store of its ideas, that Doric, Ionic, and Corinthian have ever floated uppermost, and all that has ever been produced amounts to nothing more than different arrangements and combinations of their parts, with some trifling deviations, scarcely deserving notice; the whole tending generally more to diminish than to increase the beauty of the ancient orders." Again: "The suppression of parts of

the ancient orders, with a view to produce novelty, has of late years been practised among us with full as little success; and though it is not wished to restrain sallies of imagination, nor to discourage genius from attempting to invent, yet it is apprehended that attempts to alter the primary forms invented by the ancients, and established by the concurring approbation of many ages, must ever be attended with dangerous consequences, must always be difficult, and seldom, if ever, successful. It is like coining words, which, whatever may be their value, are at first but ill received, and must have the sanction of time to secure them a current reputation."

2542. In the progress of the five orders, from the Tuscan up to the Composite, taking seven diameters for the height of the Tuscan column, and eleven for that of the Composite, if the entablature be taken of the same absolute height in all, and at the same time in height one quarter of that of the column, we shall have the height of the entablature in terms of the diameter of the column, as follows:—

In the Tuscan order	$\frac{1}{4}$ of 7	$= 1\frac{3}{4}$	entablature diameters high.
In the Doric order	$\frac{1}{4}$ of 8	$= 2$	entablature diameters high.
In the Ionic order	$\frac{1}{4}$ of 9	$= 2\frac{1}{4}$	entablature diameters high.
In the Corinthian order	$\frac{1}{4}$ of 10	$= 2\frac{1}{2}$	entablature diameters high.
In the Composite order	$\frac{1}{4}$ of 11	$= 2\frac{3}{4}$	entablature diameters high.

#### HEIGHT AND DIMINUTION OF COLUMNS.

2543. Vitruvius tells us that the ancients were accustomed to assign to the Tuscan column seven of its diameters for the height; to the Doric, eight; to the Ionic, nine; and to the Corinthian and Composite, ten. Scamozzi, the leader of the moderns, adopts similar proportions. But these are not to be considered as more than an approximation to the limits, nor as relating to the proportions between the heights and diameters of the ancient Doric examples, whereof in our First Book we have examined certain specimens. This work cannot be extended to a representation of the variety under which the orders have appeared in their various examples of each order. The works in which they are contained must be consulted for particulars of detail in this respect. Our intention is to give general information on the subject, and to follow, with few exceptions, in that respect, the precepts of Vignola, as tending to the most generally pleasing results, and as being also those which have been adopted on the Continent for general instruction in the art.

2544. We have already spoken (2524, *et seq.*) of the general proportion of the height of the entablature to that of the column as one fourth, and, without returning to the discussion of the propriety of that proportion, will only here incidentally mention that Scamozzi, Barbaro, Alberti, and Palladio have not assigned so great a height to their entablatures, chiefly, it appears, because they seemed to consider the slenderness of the columns in the more delicate orders unsuited to the reception of heavy burdens. If, however, the reader will bear in recollection what has been said at the beginning of this section relative to the supports and weights, it will directly occur to him that the practice these great masters sanctioned is not founded upon just deductions. Chambers seems to have had a glimpse of this theory, but without any notion of its developement, when he says, "It must be remembered that, though the height of an entablature in a delicate order is made the same as in a massive one, yet it will not, either in reality or in appearance, be equally heavy, for the quantity of matter in the Corinthian cornice A (*fig.* 875.) is considerably less than in the Tuscan cornice B, and the increased number of parts composing the former of these will of course make it appear far lighter than the latter." He was, however, nearer the exact truth where he speaks in a previous passage of the possibility of increasing the intervals between the columns.

2545. The diminution or tapering form given to a column, whereof all the authors find the type, whether truly or not, in that of the trunk of a tree, in the ancient examples, sometimes commences from the foot of the shaft, sometimes from a quarter or one third of its height, in which case the lower part is a perfect cylinder. Though the latter method has been mostly adopted by modern artists, the former seems more to have prevailed among the ancients. Of the method of entasis, that is, of swelling columns as they rise, we have already spoken in the First Book (144.). A curve of diminution, if we may so term it, in which the lower part does not much vary from the cylinder, but never much exceeding its boundary for the height of one third upwards, is the best, and to something like that we now come. Blondel (*Resolution des quatre principaux Problemes d'Architecture*) says, that the best and simplest instrument for the diminution of columns is that invented by Nicomedes for describing the first conchoid, which, applied at the bottom of the shaft, gives, by continued motion, both the swelling and the diminution. Vignola had not strictly anticipated Blondel in this method, which, it is said, was that used for the columns in the Pantheon; but the old master had come so near to it that we shall first describe Vignola's method, and then that proposed by Blondel. Vignola having already spoken of the common practice, says,

Fig. 876.

(Stampani's edit. *Dei cinque Ordini d'Architettura*, Roma, 1770, cap. 7. p. 51.), "In respect of this second mode, it is my own discovery, and will be soon understood by the figure, though not so well known as the first named. The measures of the column having been fixed, namely, the height of the shaft and its upper and lower diameters, from C (fig. 876.), draw an indefinite line through D perpendicular to the axis of the column. From A, the extreme point of the upper semi-diameter, to B, a point in the axis, set off CD the lower semidiameter. Through B from A draw the line ABE, cutting the indefinite line CD in E, and from the point of intersection E and through the axis of the column draw any number of rays, as EBa, whereon, from the axis towards the circumference, setting off the interval CD, any number of points aaa may be found, and through them a curve being drawn gives the swell and diminution of the shaft.

2546. This method is so far defective as to require the curve to be drawn by hand on the application of a flexible ruler through the points found. To remedy the defect, Blondel, who on investigation of the curve found it to be a conchoid, applied the instrument of Nicomedes for the purpose, the description of which instrument here follows. The height of the shaft and the upper and lower diameters of the column having been determined, as also the length (fig. 876.) of the line CDE, take three rulers, FG, ID, and AH, of which let FG and ID be fastened together at right angles in G. From top to bottom let a dovetail groove be cut down the middle of FG, and at E on the ruler ID, whose length from the centre of the groove in FG is the same as that of the point of intersection from the axis of the column, fix a pin. On the ruler AH set off the distance AB equal to the lower semidiameter of the column CD, and at the other end of the ruler cut a slit in length between EB and ED, and its breadth sufficient to admit the pin fixed at E to pass through the slit, and allow the ruler to slide thereon. Now, the middle of the groove in the ruler FG being placed exactly over the axis of the column, the ruler AH in moving along the groove will with its extremity A describe the curve AaaC, which curve is the same as that produced by Vignola's method, except that the operation is performed by the continued motion of the ruler AH. If the rulers be of an indefinite size, and the pins at E and B be made to move along their respective rulers, so as to be able to increase or diminish at pleasure the lengths AB and DE, the instrument will answer for drawing columns of any size.

2547. The diminution of the column as respects quantity is rarely in ancient examples less than one eighth of the lower diameter of the column, nor often more than one sixth, as will be seen in the subjoined examples. One sixth is the diminution recommended by Vitruvius, and followed by Vignola, in all his orders, except the Tuscan. In the following table the first column contains the order; the second, the example; the third, the height of the column in English feet and decimal parts of a foot; the fourth column shows its diameter in similar terms; and the fifth the ratio of diminution. The dimensions are from Perrault, reduced here from French to English feet.

Order.	Examples.	Height of Column in English Feet.	Diameter of Column in English Feet.	Ratio of Diminution.
Doric	Theatre of Marcellus - - - -	22-386	3-198	0-200
—	Coliseum - - - - -	24-384	2-865	0-077

2548. The recommendation of Vitruvius (lib. iii. c. 2.) to give different degrees of diminution to columns of different heights has been combated by Perrault in his notes on the passage; and we are, with Chambers, of opinion that Perrault is right in his judgment, inasmuch as the proper point of view for a column fifty feet high (*fig.* 876. unshaded part) ought not to be at the same distance as for one of fifteen, the point being removed more distant as the column increases in height, and therefore the apparent relation between the upper and lower diameters would appear the same. For supposing A to be a point of view whose respective distance from each of the columns *fg* FG, is equal to the respective heights of each, the triangles *fAg* FAG will be similar; and *Af*, or *Ah*, which is the same, will be to *Ag*, as *AF*, or its equal *AH*, is to *AG*: therefore, if *de* be in reality to be as *DE* is to *BC*, it will likewise be apparently so: for the angle *dAe* will then be to the angle *bAc*, as the angle *DAE* is to the angle *BAC*; and if the real relations differ, the apparent ones will likewise differ. "When, therefore," observes Chambers, "a certain degree of diminution, which by experience is found pleasing, has been fixed upon, there will be no necessity for changing it, whatever be the height of the column, provided the point of view is not limited; but in close places, where the spectator is not at liberty to choose a proper distance for his point of sight, the architect, if he inclines to be scrupulously accurate, may vary; though it is, in reality, a matter of no importance, as the nearness of the object will render the image thereof indistinct, and, consequently, any small alteration imperceptible." Our author afterwards adds: "It must not, however, be imagined that the same general proportions will in all cases succeed. They are chiefly collected from the temples and other public structures of antiquity, and may by us be employed in churches, palaces, and other buildings of magnificence, where majesty and grandeur of manner should be extended to their utmost limits, and where, the composition being generally large, the parts require an extraordinary degree of boldness to make them distinctly perceptible from the proper general points of view."

#### SUBDIVISION OF ENTABLATURES.

2549. We have spoken of the entablature as the fourth part of the height of the column. In general terms, its subdivisions of architrave, frieze, and cornice are obtained by dividing its height into ten equal parts, whereof three are given to the architrave, three to the frieze, and four to the cornice; except in the Roman Doric order, in which the whole height of the entablature is divided into eight parts, of which two are given to the architrave, three to the frieze, and three to the cornice. From these general proportions variations have been made by different masters, but not so great as to call for particular observation. They deviate but little from the examples of antiquity; and the ease with which they may be recollected render them singularly useful.

#### MODE OF MEASURING THE ORDERS.

2550. Several methods have been used for forming the scale of equal parts, by which the orders are measured; but they are all founded on the diameter of the column at the bottom of the shaft; for those that use the module or semi-diameter as the measuring unit (which all have done in the Doric order) must still recur to the diameter itself. The authors have also usually divided it into thirty parts, but all concur in measuring by an unit founded on the diameter. We shall follow the practice of Vignola in describing the orders, that master dividing the diameter into two equal parts, of which each is the unit of the scale for

profiling the order. The *module* for the two first orders, the Tuscan and Doric, is divided into twelve parts or *minutes*; and for the Ionic, Corinthian, and Composite orders into eighteen parts, by which minute fractions are avoided.

2551. For drawing or *profiling*, as it is called, an order, the proper way is to set out the height of the leading parts and their projections, and then proceed to the subdivisions of each. As a general rule, we may mention that it is usual to make projections of cornices nearly or quite equal to their heights.

#### APPLICATION OF THE ORDERS.

2552. The application of the orders among the ancients was exceedingly extensive. Porticoes abounded about their cities; their temples were almost groves of columns, with which also were profusely decorated their theatres, baths, basilicæ, and other public buildings, as were no less the courts, vestibules, and halls of their private dwellings. The moderns have in a great measure imitated their example, and their use has very much exceeded the limits of propriety. The maxim of Horace, "*Nec Deus interit*," has in no case been more violated by architects than in the unnecessary introduction of the orders on the façades of their buildings. The test of fitness being applied to their employment is the best that the young architect can adopt.

### SECT. III.

#### THE TUSCAN ORDER.

2553. The reader, in *fig. 877.*, has before him the geometrical representation of the Tuscan order and its details. A shows the plan of the soffit of the cornice, and B is a plan of the capital. The example is from Vignola's profile, whereon we consider it proper to remark, in conformity with an opinion before expressed (2532, 2533.), that the ovolo which crowns the cornice is an improper moulding for the situation it occupies. The substitution for it of a fillet and *cyma recta* would have been much more suitable, and would have also been more pleasant in effect.

2554. "The Tuscan order," says Chambers, "admits of no ornaments of any kind; on the contrary, it is sometimes customary to represent on the shaft of its column rustic cinctures, as at the Palace Pitti in Florence, that of the Luxembourg in Paris, York Stairs in London, and many other buildings of note. This practice, though frequent, and to be found in the works of many celebrated architects, is not always excusable, and should be indulged with caution, as it hides the natural figure of the column, alters its proportions, and affects the simplicity of the whole composition. There are few examples of these bandages in the

remains of antiquity, and in general it will be advisable to avoid them in all large designs, reserving the rustic work for the intercolumniations, where it may be employed with great propriety, to produce an opposition which will help to render the aspect of the whole composition distinct and striking." Our author proceeds to observe, that "in smaller works, of which the parts being few are easily comprehended, they may be sometimes tolerated, sometimes even recommended, as they serve to diversify the forms, are productive of strong contrasts, and contribute very considerably to the masculine bold aspect of

Fig. 877.

the composition." Le Clerc allows their propriety in the gates of citadels and prisons, and also considers them not out of place for gates to gardens or parks, for grottoes, fountains, and baths. Delorme made abundant use of them in several parts of the Thuilleries, covering them with arms, cyphers, and other enrichments. They are to be found in the detail of the Louvre, with vermiculated rustics. De Chambrai, who banishes the Tuscan order to the country, nevertheless admits that the Tuscan column may be consecrated to the commemoration of great men and their glorious actions, instancing Trajan's column, one of the proudest monuments of Roman splendour, as also the Antonine column.

2555. Having adjusted the size of the module with its subdivisions of twelve parts, so that the paper or other material on which the order is profiled may contain the whole of the order, it always being understood that the representation for practical purposes need not include the whole height of the shaft of the column, whose minutiae of diminution may form the subject of a separate drawing, the first step is to draw a perpendicular line for the axis of the column. Parallel to the base lines are then to be drawn, according to the dimensions (parts of the module) given in the table subjoined; and the beginner, as well as the more practised man, is recommended not to set up these as they are given separately, but in every case to add the succeeding dimensions to those preceding rather than to set them off one by one, which, on a small scale, causes minute errors in reading off from the scale to become in the end large in amount. By the adoption also of such a practice the work corrects itself as it proceeds. As the heights are set up, the projection of each member from the axis of the column is to be set off, and this should be always done on both sides at the same time, by which *gulling* of the paper from the point of the compasses, and errors in other respects, are avoided. The *fig. 878.* is

Fig. 878.

but the detail on a larger scale of the general representation exhibited in that preceding. The measures of each part are given in the following table.

TABLE OF THE PARTS OF THE TUSCAN ORDER.

2556. Vitruvius in this order forms the columns six diameters high, and makes their diminution one quarter of the diameter. He gives to the base and capital each one module in height. No pedestal is given by him. Over the capital he places the architrave of timber in two thicknesses connected together by dovetailed dowels. He however leaves the height unsettled, merely saying that their height should be such as may be suitable to the grandeur of the work where they are used. He directs no frieze, but places over the architrave cantilevers or mutuli, projecting one fourth part of the height of the column, including the base and capital. He fixes no measure for the cornice, neither does he give any directions respecting the intercolumniations of this order. The instructions are not so specific as those which he lays down for the other orders, and there have been various interpretations of the text, which unfortunately cannot in any of the suppositions be tested

on ancient remains. The whole height, according to the measuring unit which we have adopted from Vignola, is 16 modules and 3 parts.

2557. Palladio makes the height of his Tuscan column 6 diameters, and diminishes the shaft one fourth of a diameter. The height of the base and capital are each half a diameter. He provides no pedestal, but, instead thereof, places the base of the column on a zoccolo, or lofty plinth, whose height is equal to the diameter of the column. He leaves the intercolumniation unsettled, merely hinting that as the architraves are of timber, they, the intercolumniations may be wide. The whole height by him assigned to the order is 9 diameters and three quarters of the column. The whole height according to our scale is 19 modules and 6 parts.

2558. Serlio makes the column of the order 5 diameters exclusive of base and capital, each of which are half a diameter in height, and his diminution is one quarter of the diameter. He gives half a diameter to the height of the architrave, and an equal height to the frieze and to the cornice. His pedestal is with a plinth and base, a die, and cymatium, the whole being a third of the height of the column. He gives no rules for the intercolumniations, though in book 4. he inserts a diagram wherein intercolumns appear, merely saying that they are equal to 3 diameters. The total height according to our measure is 19 modules and 3 parts.

2559. Scamozzi makes the shaft of his column 6 diameters, and diminishes it one fourth part of its diameter. The heights of the base and capital are each half a diameter. To the entablature he assigns for height one fourth of the height of the column, including its base and capital, less half its diameter. He places a sort of triglyph in the frieze, which arises from a misconception of the text of Vitruvius. The height of his pedestal is a fourth part of that of the column, with base and capital, less half a diameter. The whole height in our measure is 21 modules and 9 parts.

#### SECT. IV.

##### THE DORIC ORDER.

2560. The Doric order of the moderns is of two sorts: mutular and denticular, the former is represented in *fig. 879*. A is a plan of the sofite of the corona; B, a plan of the

Fig. 879.

capital; and C, a plan of the base. In the frieze the channelled projections are called *triglyphs*, and the spaces between them *metopæ*, which should in breadth be equal to their  
Y y 3

height, which is that of the frieze. The shaft is usually channelled with twenty *flutes*. Over the triglyphs are distributed *mutules* or modillions, and another peculiarity is the introduction of *guttae* or *drops*, which decorate the soffit of the cornice and the feet of the triglyphs.

2561. Daviler, speaking of the two Doric entablatures given by Vignola, admires the elegance of their composition, and scarcely knows which of them to select as the most beautiful. "The first" (or denticular), hereafter immediately subjoined, says Chambers, following that author, "which is entirely antique, is the lightest, and consequently properest for interior decoration or objects intended for near inspection; the other, composed by Vignola himself from various fragments of antiquity, being bolder, and consisting of larger parts, seems better calculated for outside works and places where the point of view is either distant or unlimited. On polygonal plans, however, the mutule cornice must be avoided, because the soffites of the angular mutules would form irregular and very disagreeable figures: neither should it be employed in concaves of small dimensions, for the same reason; nor in places where frequent breaks are requisite, it being extremely difficult, often impossible, to prevent the mutules from penetrating and mutilating each other in various unsightly manners; and wherever this cornice is used on a convex surface, the sides of the mutules must be made parallel, for it would be both disagreeable and unnatural to see them broader, and consequently heavier in front than where they spring out of the mutule band." We have elsewhere observed that there is very great difficulty in distributing the parts of the Doric entablature, on account of the intervals between the centres of the triglyphs, which necessarily confine the composer to intercolumniations divisible by three modules, thus producing spaces which are often too wide or too narrow for his purposes.

Fig. 880.

2562. In *fig. 880.* the entablature of the mutular Doric order is given to a larger scale than that of the preceding figure; and we subjoin, as in the Tuscan order, —

TABLE OF PARTS OF THE ENTABLATURE OF THE MUTULAR DORIC.

Mouldings whereof the Parts are composed.				Heights of Mouldings in Parts of a Module.	Projections from Axis of Column in Parts of a Module.
Cornice A, 18 parts.	Fillet of the corona	-	-	1	34
	Cyma	-	-	3	31
	Fillet	-	-	$\frac{1}{2}$	31
	Cyma reversa	-	-	1	$30\frac{1}{4}$
	Corona	-	-	$3\frac{1}{2}$	30
	Cyma reversa	-	-	1	$29\frac{1}{2}$
	Mutule	-	-	3	$28\frac{1}{2}$
	Drip	-	-	$\frac{1}{2}$	28
	Gutta of the mutule	-	-	$\frac{1}{2}$	26
	Echinus, or quarter round	-	-	2	$13\frac{1}{2}$
	Fillet	-	-	$\frac{1}{2}$	$11\frac{1}{2}$
	Capital of the triglyph	-	-	2	11
Frieze B, 18 parts.	Triglyph	-	-	18	$10\frac{1}{2}$
	Metope	-	-	18	10
Architrave C, 12 parts.	Listel	-	-	2	12
	Capital of the guttæ	-	-	$\frac{1}{2}$	$11\frac{1}{2}$
	Guttæ	-	-	$1\frac{1}{2}$	$11\frac{1}{2}$
	First fascia	-	-	6	$10\frac{1}{2}$
	Second fascia	-	-	4	10

D is the plan of a triglyph to double the scale.  
E is the plan of the round or square guttæ.  
F is the elevation of the triglyph and its guttæ.

2563. To obviate the difficulties mentioned in 2561. relative to the triglyphs, they have often been omitted and the entablature left plain, as in the Coliseum at Rome, the colonnades of St. Peter's of the Vatican, and in many other buildings. This, says Chambers, is an easy expedient; but as it robs the order of its principal characteristic distinction, the remedy is a desperate one, and should only be employed as a last resource.

2564. The Doric order was used by the ancients in temples dedicated to Minerva, to Mars, and to Hercules. In modern buildings, Serlio (lib. iv. c. 6.) recommends it in churches dedicated to saints remarkable by their suffering for the Christian faith. Le Clerc suggests its use for military buildings. "It may," says Chambers, "be employed in the houses of generals, or other martial men, in mausoleums erected to their memory, or in triumphal bridges and arches built to celebrate their victories."

2665. As the difference between the mutular and denticular Doric lies entirely in the entablature, we give in the following table the whole of the details of the order,

Fig. 881.

observing, that from the capitals downwards, the measures assigned to them are the same for each. Fig. 881. represents the entablature of the denticular Doric and its parts,

which, with those of the capital, base, and pedestal, are in *fig. 882.* given to a larger

Fig. 882.

scale, as we have before represented the parts of the Tuscan order. The general table is subjoined : —

Members composing the Order.				Heights in Parts of a Module.	Projections in Parts of a Module from Axis of Column.

	First plinth	-	-	-	4	21 $\frac{1}{2}$

2566. Vitruvius, with more clearness than in the others, describes the Doric order (book iv. chap. iii.). In order to set out its proportions, he tells us, though not giving a direct rule, that its pedestal is composed of three parts, the cymatium or cornice, the die, and the base; and that the base and cimatium are composed of many mouldings, whose individual proportions, however, he does not give. He assigns no particular base to the Doric order; but, nevertheless, places under half a diameter in height the attic base, whose members are the plinth, small fillet, scotia, and the upper torus with its superior and inferior fillets, together with the apophyge of the column. He gives to the projection of the base a fifth part of the diameter of the column. The height of the shaft he makes of 6 diameters, and its diminution a sixth part of the diameter. The capital's height he makes equal to half a diameter, and divides it into three parts, one for the abacus and its cymatium, another for the echinus and its fillets, the third for the hypotrachelium. To the architrave he assigns the height of one half diameter of the column, and to the frieze 50 parts of the module (semidiameter divided into 30 parts), including the fascia, forming the capital of the triglyphs. His cornice consists of 30 parts of the module, and its projection 40. The whole height which he gives to the order is, in the measure here adopted, 17 modules and 20 parts.

2567. Palladio makes the Doric pedestal rather less than 2 $\frac{1}{2}$  diameters of the column, dividing it into three parts, the base, die, and cymatium. To the die he assigns nearly a diameter and one third of the column. To the cymatium a little more than one third of the diameter. He uses the attic base to the order, but, for the sake of carrying off the water, turns the plinth into an inverted cavetto (*guscio*), ending in the projection of the

cymatium of the pedestal. To the shaft of the column he assigns various proportions, directing that if accompanied with pilasters, it should be of the height of  $8\frac{1}{2}$  diameters, and if entirely isolated, 7 or at most 8 diameters high. He cuts the shaft into 24 flutes, and diminishes it the tenth part of its diameter. The height of his capital is half a diameter, and, like the annotators on Vitruvius, he decorates the neck or frieze, as they both call it, with roses, adding, however, other flowers, and making its projection a little more than a fifth part of the diameter. To the architrave, frieze, and cornice he gives a little more than one fourth part of the height of the column, so that the whole height of his order is in our measure 24 modules and a fraction above  $2\frac{1}{2}$  parts.

2568. Serlio makes the height of the pedestal of his column a little less than 3 diameters, with its base, die, and cymatium. The height of the die is set up equal to the diagonal of a square, formed on the plinth of the column. The height of the cymatium, according to the strict text of Serlio, should not be less than that of the base; but he altogether omits any mention of its projection. His base is the attic base, to which he assigns a projection of a quarter of a diameter. The column is 6 diameters high, and has 20 flutes. His capital differs only from that of Vitruvius in its projection, which is rather more. The architrave and frieze do not much differ from those already described. The projection given to the cornice is equal to its height. The whole height in our measures amounts to 23 modules and 5 parts.

2569. The Doric order as described by Seamozzi is not very dissimilar to those already described. The pedestal is by him made 2 diameters and a little more than a quarter, with a base, die, and cymatium, and the projection barely a quarter of the diameter of the column, to which he gives the attic base. His column is  $7\frac{1}{2}$  diameters high, and the diminution a fifth part of the diameter. There are 26 flutes on the shaft, separated from each other by fillets, whose width is one third of the flute. This author gives three different sorts of capitals for the order: the first has three annulets; the second has only the lower annulet, the two upper ones being changed to an astragal; the third, instead of the two lower annulets, has a cyma reversa. Lastly, above the corona he places a cyma reversa, and in the other parts does not vary much from the preceding authors, especially in the frieze and architrave, except that in the last he uses two fasciæ. To the cornice he assigns the projection of five sixths of a diameter of the column. His whole entablature is a little less than one fourth the height of the column, including base and capital. The whole height of the order in our measures is 23 modules and 8 parts.

2570. In *fig. 883.* the profile of the Grecian Doric from the Parthenon at Athens is given. Though very different to those we have already described of this order, the resemblance is still considerable. Its character is altogether sacred and monumental, and its application, if capable of application to modern purposes, can scarcely be made to any edifice whose general character and forms are not of the severest and purest nature. The various absurd situations in which the Grecian Doric has been introduced in this country, has brought it into disrepute; added to which, in this dark climate the closeness of the intercolumniations excludes light, which is so essential to the display of architecture under the cloudy skies with which we are constantly accompanied in high latitudes. The diameter of the columns in the original is 6 feet 2·7 inches.

2571. Lest we may be reproached with neglecting to submit to the student in this place (and the remark equally applies to the following section on the Ionic order) more examples of the Grecian Doric, we would here observe that this work is not to stand in place of a parallel of the orders. Nothing would have been easier than to have placed before him an abundance of examples; but they must be sought elsewhere, inasmuch as the nature of our labours requires general, not special, information in this respect. We have not, however, refrained in the first book (142, *et seq.*) from entering into details respecting the Grecian Doric, which we consider much more valuable to the reader than would be the exhibition of a series of profiles of its principal examples. We have, moreover, at that place, suggested some criteria of their comparative antiquity. We do not think the nice copying of a profile into a modern work any other than a disgraceful exhibition of the want of ability in the man, we cannot call him artist, who adopts it, and shall be much better pleased to leave the student in doubt, so that he may apply himself *pro re natâ* to the matter which calls his genius into play. From what we have said on the orders in Sect. II. of this Book, (2523, *et seq.*), relative to the order, and on mouldings

Fig. 883.

(2532, *et seq.*), it must be quite clear that the variety of every order, keeping to first principles, has not been yet exhausted, neither is it likely to be so.

	Third step or plinth - - - - -	-	-	-	6·90	30·84

2572. The minutiae of the Grecian Doric, as we have just observed, cannot be given in a general work of this nature. In its smaller refinements it requires plates on a much larger scale than this volume allows. The reader, therefore, must be referred to *Stuart's Antiquities of Athens* (original edition), and the publications of the Dilettanti Society, for further information on the subject of the Grecian Doric. All that was here possible was to give a general idea of the order. In the figure, E is the section of the capitals of the inner columns of the temple on a larger scale. DD relate to the principal columns. F is a section of one of the antæ or pilasters to double the scale of the capital. The centre intercolumniation 4 modules  $\frac{55}{100}$  from axis to axis of columns. The principal Grecian Doric examples are — the Parthenon, the temple of Theseus, the propylæa and the portico of the Agora at Athens; the temple of Minerva at Sunium; the temple at Corinth; of Jupiter Nemæus, between Argos and Corinth; temple of Apollo and portico of Philip in the island of Delos; the temple of Jupiter Panhellenius at Egina, and of Apollo Epicurius at Phigalia; the two temples at Selinus; that of Juno Lucina and Concord at Agrigentum; the temple at Egesta, and the three temples at Paestum. (See 142, *et seq.*)

## SECT. V.

## THE IONIC ORDER.

2573. Of the Ionic order there are many extant examples, both Grecian and Roman; and, except the debased later examples of the latter, there is not that wide difference between them that exists between the Grecian and Roman Doric. The Ionic has been considered as deficient in appearance as compared with the other orders, on account of

the irregularity of its capital, which, on the return, presents difficulties in use. These difficulties are not obviated by the practice of the Greeks, who made an angular volute on each extremity of the principal façade, and then returned the face of the capital. With all our respect for Greek art, we think the expedient, though ingenious, a deformity; albeit, in the case of the type being a timber architrave, we must admit that the face of the capital should lie in the direction of the superincumbent beam.

2574. In the example given (*fig. 884.*) we have, as in the examples of the preceding

Fig. 884.

orders, selected the profile of Vignola as the most elegant of the moderns; and the reader will here recollect that in the Ionic, Corinthian, and Composite orders, the module or semi-diameter of the column is divided into 18 parts. In the figure, A is a plan of the soffit of the cornice, and B a plan of the capital. The method of tracing the volute will be given in a subsequent figure: previous to which, as in the orders already given, we subjoin a table, showing the heights and projections of the parts of the order.

The flutes in this order are separated by a listel.

2575. The letters to the leading divisions of the above table refer to the *fig. 885.*, wherein the parts are drawn to a larger scale, and wherein I is the eye of the volute, presently to be described.

Fig. 885.

2576. Fig. 886. shows the method of drawing the volute, the centre of whose eye, as it is called, is found by the intersection of an horizontal line from E, the bottom of the

Fig. 886.

echinus, with a vertical from D, the extremity of the cyma reversa. On the point of intersection, with a radius equal to one part, describe a circle. Its vertical diameter is called the *catetus*, and forms the diagonal of a square, whose sides are to be bisected, and through the points of bisection (see I, fig. 885.) the axes 1, 3 and 2, 4 are to be drawn, each being divided into 6 equal parts. The points thus found will serve for drawing the exterior part of the volute. Thus, placing the point of the compasses in the point 1, with the radius 1D, the quadrant DA is described. With the radius 2A another quadrant may be described, and so on. Similarly, the subdivisions below the points used for the outer lines of the volute serve for the inner lines. The total height of the volute is 16 parts of a module, whereof 9 are above the horizontal from E, and 7 below it.

2577. Vitruvius, according to some authors, has not given any fixed measures to the pedestal of this order. Daniel Barbaro, however, his commentator, seems to think otherwise; and, on this head, we shall therefore follow him. The height of the pedestal is made nearly a third part (including its base and cymatium) of the height of the column. To the base of the column he assigns half a diameter, and to the shaft itself nearly 8 diameters, its surface being cut into 24 flutes, separated by fillets from each other. His method of describing the volute is not now thoroughly understood; and it is, perhaps, of little importance to trouble ourselves to decypher his directions, seeing that the mode of forming it is derived from mathematical principles, as well understood now as in the days of the author. The architrave he leaves without any fixed dimensions, merely saying that it must be larger or smaller according to the height of the columns. He prescribes, however, that the architrave, frieze, and cornice should together be somewhat less than a sixth part of the height of the column, with its base and capital. The total height he makes the order, according to our measures, is 25 modules and nearly 9 parts.

2578. Palladio gives to the pedestal 2 diameters and nearly two thirds of the height of the column. He adopts the attic, though without rejecting the Ionic base, and makes it half a diameter high, adding to it a small bead, which he comprises in the height of the shaft, which he makes 8 diameters in height. To the architrave, frieze, and cornice, taken together, he assigns a little less than one fifth of the height of the column, including its base and capital, and makes the projection of the cornice equal to its height. The total height of the order, in our measures, is, according to him, 27 modules and nearly 8 parts.

2579. Serlio, in this order more than any of the others, varies from Vitruvius. To the pedestal he gives, including base, die, and cymatium, a little more than a third part of the height of the column, with its base and capital. To the shaft of the column he gives 7 diameters, and diminishes it a sixth part of its diameter. His capital is that of Vitruvius, as far as we can understand that master. His mode of constructing the volute differs from other authors. His directions are, that having found the *catetus*, which passes through the centre of the eye, it must be divided into eight parts, from the abacus downwards, one whereof is to be the size of the eye of the volute, four remain above the eye, and three below that part comprised below the eye. The *catetus* is then divided into six parts, properly numbered by figures from 1 to 6. With one point of the compasses in 1, and the other extended to the fillet of the volute, he describes a semicircle, and so on with semicircles consecutively from 2 to 6, which will ultimately fall into the eye of the volute. We cannot speak in high terms of Serlio's method, and therefore have thought it unnecessary to accompany the description with a figure. It is rather a clumsy method, and we fear, if exhibited in a figure, would not satisfy our readers of its elegance. The height of his architrave, frieze, and cornice together is a little less than a fourth part of the height of the column, including the base and capital. The whole height of his order, in our measures, is 25 modules and 6 parts.

2580. Scamozzi directs that the pedestal shall be with its base and cornice two diameters and a half of the column. He uses the attic base, and, like Palladio, gives an astragal above the upper torus. To the shaft of the column he assigns a height of little less than 8 diameters, and makes its diminution a sixth part of the diameter. He adopts the angular capital, something like the example of that in the temple of Fortuna Virilis. The height of his architrave, frieze, and cornice is a little less than a fifth part of the height of the column, with its base and capital. The total height of his order, in our measures, is 26 modules.

2581. The principal examples of the Grecian Ionic are in the temples of Minerva Polias, of Eretheus, and the aqueduct of Hadrian, at Athens; in the temple of Minerva Polias at Priene; of Bacchus at

Fig. 887

Tees; of Apollo Didymæus at Miletus; and of the small temple on the Ilyssus, near Athens, whereof in *fig. 887.* the profile is given, and below, a table of the heights and projections of the parts. It is to be observed, that in the Grecian Ionic volute the fillet of the spiral is continued along the face of the abacus, whilst in the Roman examples it rises from behind the ovolo. Some of the Athenian examples exhibit a neck below the echinus, decorated with flowers and plants. The entablatures of the early Ionic are usually very simple. The architrave has often only one fascia, the frieze is generally plain, and the cornice is composed of few parts. In Book I. Chap. II. (153, *et seq.*) we have already examined the parts of the Grecian Ionic, and thereto refer the reader.

The height from the top of the echinus to the centre of the eye of the volute is 15·72 parts.

Total projection of the volute from axis of column, 27·90.

The flutes are elliptical on the plan (see *fig. 887.*), and the distance between axes of columns, 6 modules 3·24 parts.

SECT. VI.

THE CORINTHIAN ORDER.

2582. For the Corinthian order, we must seek examples rather in Rome than in any part of Greece. The portico at Athens, and the arch of Hadrian at Athens, do not furnish us with specimens of art comparable with the three columns in the Campo Vaccino, belonging, as is generally supposed, to the temple of Jupiter Stator. Those in the temple near Mylassa, and the Incantata, as it is called, at Salonica, do not satisfy the artist, as compared with the examples in the remains of the temple of Mars Ultor at Rome, the temple of Vesta at Tivoli, and others, for which the reader may refer to Desgodetz.

2583. The reader is again here reminded that the module or semidiameter is to be

Fig. 888.

divided into eighteen parts. In *fig. 888.* is a representation of the Corinthian order, whose measures are given in the following table :—

Fig. 889

2584. *Fig. 889.* shows the details of the entablature, &c. and also the profile and front of the Corinthian modillion to a larger scale. On the profile is shown the caisson or sunk panel on the soffit of the corona. The height is six parts, and the projection sixteen. As seen in the figure, a distance equal to three parts and a half is taken for the height of the smaller volute, and on this distance a scale of sixteen equal parts is made; the figure shows the dimensions to be given to the small squares, whose angles serve as centres to describe the curves. Having drawn the line *AB*, it is divided into four equal parts by lines perpendicular to it, which, meeting vertical lines from *A* and *B*, give the points, which serve as centres for striking the curve of the modillions. The acanthus leaf which supports it, as well as the curves which form the profile of the roses in the caisson, are also struck by compasses.

2285. In *fig. 890.*, which exhibits the method of drawing the Corinthian capital, one half of the plan shows the capital in plan, and the other half of it laid down diagonally. Having drawn the axis of the plan correspondent to the axis of the elevation of the capital, with a radius equal to two modules, describe a circle, which divide into sixteen equal parts. Their lines of division will each correspond to the centre of each leaf. The vase of the capital is determined by a circle whose radius is  $14\frac{1}{2}$  parts. The figure shows the circles which bound the leaves upwards on the vase.

2586. The elevation shows the heights whereon are carried the projections of the plan.

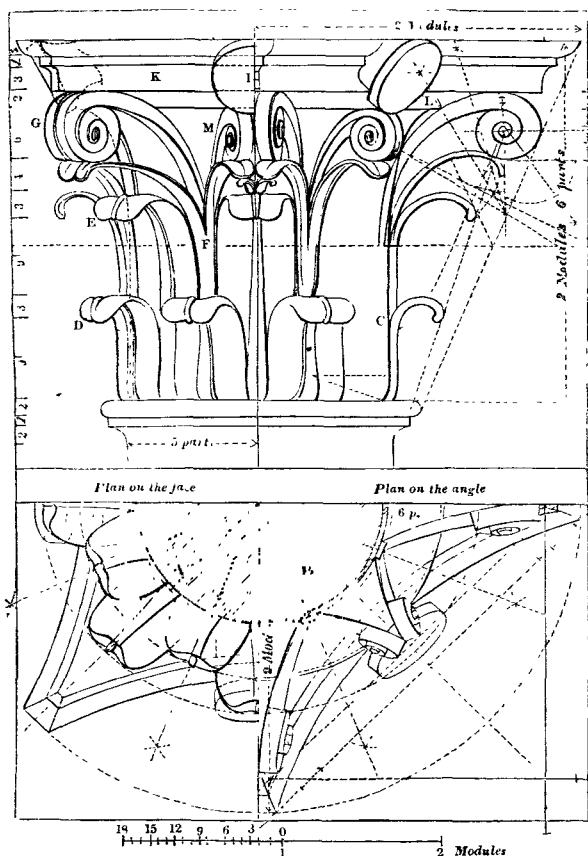

Fig. 890.

Above the leaves come the sixteen volutes, whereof the eight larger ones support the four angles of the abacus, and the eight smaller ones support the flowers which decorate the middle of the abacus. The volutes seen in profile may be drawn geometrically with the compasses, but they are always more agreeable and easy when drawn by the eye with a hand which feels the contours.

The different parts of the capital are as follow: A, plan of the leaves and abacus; B, plan of the larger and smaller volutes; C, the vase or body of the capital; D, the first tier of leaves; E, the second tier of leaves; F, the cauliculus; G, the larger volute; H, the smaller volute; I, the flower; K, the abacus; L, the lip of the vase.

2587. Vitruvius is scanty in the information he gives on the Corinthian order, and what he says respecting it relates more to the origin of the capital and the like than to the proportions of the detail. He makes the capital only 1 diameter high, and then forms upon the plan a diagonal 2 diameters long, by means whereof the four faces are equal according to the length of the arc, whose curve will be the ninth part in length and its height the seventh part of the capital. He forms the order with a pedestal, with base and cornice, as Daniel Barbaro would have it. The whole height given to it in our measures is about 27 modules and 2 parts.

2588. Palladio uses the pedestal with its ordinary subdivisions, making it between a third and fourth part of the height of the column, including its base and capital. To the base he gives 1 module, the shaft of the column a little less than 8 diameters, and places twenty-four flutes upon it, which two thirds downwards are channelled, and on the other or lower third neatly fitted with convex pieces of segments of cylinders called *cablings*. He makes the capital 1 diameter and a sixth in height, giving it two tiers of leaves, caulicoli, and abacus. To the architrave, frieze, and cornice he assigns a little less

than a fifth part of the column, including the base and capital. The whole height given to the order by this author is about 27 modules and 10 parts of our measures.

2589. Serlio makes his pedestal pretty nearly as the rest. To the base of the column he assigns half a diameter for the height, when that is about level with the eye, but when much above it he directs all the members to be increased in height accordingly, as where one order is placed above another, he recommends the number of parts to be diminished. To the shaft of the column he gives a little more than 7 diameters, and to the capital the same height as that given by Vitruvius, whom, nevertheless, he considers in error, or rather that some error has crept into the text, and that the abacus ought not to be included in the height. The height of the architrave, frieze, and cornice he makes a little less than a fourth part of the column, including its base and capital. The whole of the order, according to him, is 28 modules and a little more than 1 part of our measures.

2590. Scamozzi gives to the pedestal of this order the height of 3 diameters and one third, composing it with the usual parts of base, die, and cornice; to the base of the column the same height and mouldings as Palladio. To the shaft of the column he assigns the height of 8 diameters and one third, and diminishes it on each side an eighth part of its thickness at bottom. The capital is of the same height as that by Palladio. The architrave, frieze, and cornice he directs to be a little less than a fifth part of the height of the column. By our measures the whole height of his order is 30 modules and 20 parts.

## SECT. VII.

### THE COMPOSITE ORDER.

2591. The Composite order, as its name imports, is a compound of others, the Corinthian and Ionic, and was received into the regular number of orders by the Romans. Philander, in his notes on Vitruvius, has described its proportions and character. Its capital consists, like the Corinthian, of two ranges of acanthus leaves distributed over the surface of a vase, but instead of the stalks or branches, the shoots appear small and as though flowering, adhering to the vase and rounding with the capital towards its middle. A fillet terminates the vase upwards, and over the fillet an astragal is placed, and above that an echinus, from which the volutes roll themselves to meet the tops of the upper tier of leaves, on which they seem to rest. A large acanthus leaf is bent above the volutes, for the apparent purpose of sustaining the corner of the abacus, which is dissimilar to that of the Corinthian order, inasmuch as the flower is not supported by a stalk seemingly fixed on the middle of each face of the abacus. The principal examples of

Fig. 891.

the order are at Rome, in the temple of Bacchus, the arches of Septimius Severus, of the Goldsmiths, and of Titus; also in the baths of Dioclesian.

2592. Fig. 891. (see preceding page) is a representation of Vignola's profile of the order. Its measures are subjoined in the following table: —

2593. The flutes in this order are separated by a fillet between them, and are, when used, twenty-four in number.

Fig. 592.

2594. *Fig. 892.* (see preceding page) shows the parts of the entablature, base, and pedestal to a larger scale, and *fig. 893.* gives, similarly, a more intelligible, because larger, represent-

Fig. 893.

ation of the mode of setting up the capital, which, as we have already observed, has only eight volutes. In this figure A is the plan, as viewed frontwise; B, that of the capital, viewed diagonally; C, the vase or body of the capital; D, the first tier of leaves; E, the second tier of the same; F, the volutes; G, the flower; H, the abacus.

2595. Vitruvius has not given any instructions on this order; we are therefore obliged to begin our parallel, as in the other orders, with —

2596. Palladio, whose examples of it are light and much decorated. To the pedestal's height this master assigns 3 diameters and three eighths of the column, adding to it a lower plinth of the height of half a diameter. He makes the base of the column half a diameter in height, and assigns to the shaft 8 diameters and a little more than one fourth, and cuts on it twenty-four flutes. The height of this capital is 1 diameter and a sixth, his volutes being very similar to those he prescribes for his Ionic. The architrave, frieze, and cornice he makes a little less than a fifth part of the height of the column. The whole height of his profile in our measures is 30 modules and 12 parts.

2597. Serlio seems to have founded his profile of this order upon the example in the Coliseum at Rome. He makes the height of the pedestal a little less than 4 diameters of the column. To the shaft of the column he assigns 8 diameters and a half. To the height of the capital he gives 1 diameter, differing therein from his profile of the Corinthian order in the disposition of the volutes and leaves. His entablature, which is a little less in height than one fourth of the column, he divides into three equal parts for the

architrave, frieze, and cornice. The total height of his profile in our measures is 32 modules and 9 parts, being much higher than that of Palladio.

2598. Scamozzi's profile greatly resembles that of Palladio. His pedestal is 3 diameters, and the base of his column half a diameter in height. The shaft of his column, without base or capital, is 8 diameters and one twelfth high, and the capital 1 diameter and a sixth. The entablature is one fifth part of the column in height, and the whole of the profile in our measures is nearly 29 modules and 7 parts.

## SECT. VIII.

## PEDESTALS.

2599. We think it necessary to devote a small portion of this chapter to the consideration of pedestals, on account of the great difference which exists in the examples of the orders, and this we shall place in a tabular form, previous to the general remarks it will be necessary to make.

TABLE SHOWING THE HEIGHT OF PEDESTALS IN ANCIENT AND MODERN WORKS.

				Plinth in Minutes.	Mouldings above Plinth in Minutes.	Die in Minutes.	Cornice in Minutes.	Total Height in Minutes.
Doric	Palladio	-	-	26	14	80	20	140
	Scamozzi	-	-	30	15	68½	22½	136¼
Ionic	Temple of Fortuna Virilis	-	-	44	19¾	93¾	23¼	180¾
	Coliseum	-	-	33¼	9½	81½	17	141½
	Palladio	-	-	28¾	14¾	97¾	21½	162½
	Scamozzi	-	-	30	15	82½	22½	150
Corinthian	Arch of Constantine	-	-	17½	29	153	29½	228
	Coliseum	-	-	23	11½	78	19¼	131¾
	Palladio	-	-	23½	14½	93	19	150
	Scamozzi	-	-	30	15	132½	22½	200
Composite	Arch of Titus	-	-	55	30	141	29	255
	Arch of the Goldsmiths	-	-	46	25¼	144½	25¼	241
	Arch of Septimius Severus	-	-	30	30⅝	140½	29⅝	182⅝
	Palladio	-	-	33	17	133	17	200
	Scamozzi	-	-	30	15	112½	22½	180

2600. The minutes used in the above table are each equal to one sixtieth of the diameter of the shaft.

2601. Whether the pedestal is to be considered a component part of an order is of little importance. There are so many cases that arise in designing a building, in which it cannot be dispensed with, that we think it useful to connect it with the column and entablature, and have consequently done so in the examples already given of the several orders. Vitruvius, in the Doric, Corinthian, and Tuscan orders, makes no mention of pedestals, and in the Ionic order he seems to consider them rather as a necessary part in the construction of a temple than as belonging to the order itself.

2602. A pedestal consists properly of three parts, the base, the die, and the cornice. "Some authors," says Chambers, "are very averse to pedestals, and compare a column raised on a pedestal to a man mounted on stilts, imagining they were first introduced merely through necessity, and for want of columns of a sufficient length. "It is indeed true," he continues, "that the ancients often made use of artifices to lengthen their columns, as appears by some that are in the baptistery of Constantine at Rome; the shafts of which, being too short for the building, were lengthened and joined to their bases by an undulated sweep, adorned with acanthus leaves; and the same expedient has been made use of in some fragments which were discovered a few years ago at Nismes, contiguous to the temple of Diana. Nevertheless, it doth not seem proper to comprehend pedestals in

the number of these artifices, since there are many occasions on which they are evidently necessary, and some in which the order, were it not so raised, would lose much of its beautiful appearance. Thus, within our churches, if the columns supporting the vault were placed immediately on the ground, the seats would hide their bases and a good part of their shafts; and in the theatres of the ancients, if the columns of the scene had been placed immediately on the stage, the actors would have hid a considerable part of them from the audience; for which reason it was usual to raise them on very high pedestals, as was likewise necessary in their triumphal arches; and in most of their temples the columns were placed on a basement or continued pedestal (*stylobata*), that so the whole might be exposed to view, notwithstanding the crowds of people with which these places were frequently surrounded. And the same reason will authorise the same practice in our churches, theatres, courts of justice, or other public buildings where crowds frequently assemble. In interior decorations, where, generally speaking, grandeur of style is not to be aimed at, a pedestal diminishes the parts of the order, which otherwise might appear too clumsy; and has the farther advantage of placing the columns in a more favourable view, by raising their base nearer to the level of the spectator's eye. And in a second order of arcades there is no avoiding pedestals, as without them it is impossible to give the arches any tolerable proportion. Sometimes, too, the situation makes it necessary to employ pedestals, an instance of which there is in the Luxembourg at Paris; where, the body of the building standing on higher ground than the wings, the architect was obliged to raise the first order of the wings on a pedestal, to bring it upon a level with that of the body or *corps de logis* of the building, which stands immediately on the pavement."

2603. The dies of pedestals are occasionally decorated with tablets or with sunk panels whose margins are moulded; but, generally speaking, such practices are to be avoided. In very large pedestals the surface may be thus broken, as in single monumental columns, which, at best, are but paltry substitutes for originality. Habit has reconciled us to view with pleasure the Trajan and Antonine columns, the monument of London, and the column of Napoleon in the Place Vendôme at Paris, in each of which the pedestals are ornamented in some way or other, so as to tell in some measure the story of the person in whose honour they were erected, or, as in the basso-relievo of the London column, the event which it records. But care must be taken when inscriptions are used to preserve a rigid adherence to truth, and not to perpetuate a lie, as was the case in the monument just named, against a most worthy portion of the people of the British empire.

2604. As respects the employment of pedestals, we should advise the student, except under very extraordinary circumstances, to avoid the use of them under columns which are placed at a distance from the main walls of an edifice, as, for example, in porches peristyles, or porticoes, — a vice most prevalent in the Elizabethan architecture, or rather the cinque-cento period, which the people of this day are attempting with all its absurdities to revive. Here we must again quote our author, Sir William Chambers, whose excellent work we have used above, and on which we shall continue to draw largely. "With regard," he says, "to the application of pedestals, it must be observed, that when columns are entirely detached, and at a considerable distance from the wall, as when they are employed to form porches, peristyles, or porticoes, they should never be placed on detached pedestals, as they are in some of Scamozzi's designs, in the temple of Scisi (Assisi) mentioned by Palladio, and at Lord Archer's house, now Lowe's hotel, in Covent Garden; for then they indeed may be compared to men mounted on stilts, as they have a very weak and tottering appearance. In compositions of this kind, it is generally best to place the columns immediately on the pavement, which may be either raised on a continued solid basement, or be ascended to by a flight of fronting steps, as at St. Paul's, and at St. George's Bloomsbury; but if it be absolutely necessary to have a fence in the intercolumniations, as in the case of bridges or other buildings on the water, or in a second order, the columns may then, in very large buildings, be raised on a continued plinth, as in the upper order of the western porch of St. Paul's, which in such case will be sufficiently high: and in smaller buildings, wherever it may not be convenient or proper to place the balustrade between the shafts, the columns may be placed on a continued pedestal, as they are in Palladio's designs for Signor Cornaro's house at Piombino, and at the villa Arseri, near Vicenza, another beautiful building of the same master." The same author continues: "The base and cornice of these pedestals must run in a straight line on the outside throughout, but the dies are made no broader than the plinths of the columns, the intervals between them being filled with balusters, which is both really and apparently lighter than if the whole pedestal were a continued solid." The author quoted then proceeds to caution the student against the employment of triangular, circular, and polygonal pedestals, and such as are swelled and have their die in the form of a baluster, or are surrounded by cinctures.

These extravagances were rife in the age of Louis XV., but notwithstanding the zeal of the jobbing upholsterers and decorators of the present day, who are the curse of all architectural art, we hope they will never be permanently revived in this country, though their introduction has already proceeded to a considerable extent.

## SECT. IX.

## INTERCOLUMNIATIONS.

2605. An intercolumniation is the clear distance between two columns measured at the lower diameter of their shafts. This distance must depend principally on the order employed: in the Tuscan, for example, the nature of its composition allows a greater width between columns than would be admissible in the Corinthian order, independent of what has already been stated in Sect. II. (2524, *et seq.*) in respect of supports and loading; and this because of the enrichments of the several orders requiring that they should take their departures (to use a phrase borrowed from another science) from the axes of their respective columns. The ancient names (which are still preserved) of the different intercolumniations are described by Vitruvius in his second and fourth books. They are — the *pycnostyle*, wherein the space between the columns is 1 diameter and a half, as its etymology from *πυκνός* and *στυλος* imports (thick in columns), an intercolumniation used only in the Ionic and Corinthian orders; the *systyle* (*συστυλος*, with columns a little more apart), wherein the interval between the columns is a little greater; the *eustyle* (*ευστυλος*, or well-contrived interval), wherein the intercolumniation is of 2 diameters and a quarter; the *diastyle* (*διαστυλος*, with a more extended interval between the columns), having an intercolumniation of 3 diameters; and the *araostyle* (*αραιστυλος*, with few columns), wherein the interval is 4 diameters. In the Doric order the triglyphs necessarily regulate the intercolumniations, inasmuch as the triglyph should fall over the axis of the column; hence the intercolumniations in this order are either systyle monotriglyph (that is, with a single triglyph in the intercolumniation), or  $1\frac{1}{2}$  diameter; diastyle, or of  $2\frac{3}{4}$  diameters; or araostyle, which will make the interval 4 diameters, as will be immediately understood on reference to *fig. 894.*; wherein A is the systyle monotriglyph intercolumniation of 3 modules; B, that of the diastyle, or 6 modules; and C, the araostyle, or of 8 modules. The intercolumniation marked D serves for the application of coupled columns, wherein the rule seems necessarily to be that the space between the columns may be increased, so that the requisite number of supports according to the order and intercolumniation is preserved.

Fig. 894.

Fig. 895.

2606. The intervals of the Tuscan order are indicated in *fig. 895.*, wherein A shows the intercolumniation called eustyle of  $4\frac{1}{4}$  modules; B, the diastyle of 6 modules; and C, the araostyle of 8. D, of 1 module, is the space of coupled columns.

The intercolumniations in this order are scarcely susceptible of rules other than those we have indicated in our previous discussion on the orders generally in Sect. II. (2523, *et seq.*), wherein we have entered on the subject at such length that we refrain from saying more in this place. We may, however, observe, that the application of the principles there mentioned are so intimately connected with this section, that the separation of one from the other would destroy all our scheme for keeping the student in the right path. Hereafter the principles in question will be applied to and tested on arcades.

2607. In *fig. 896.*, of Ionic intercolumniations, A is the eustyle arrangement; B, that of the diastyle; C, that of the aræostyle; and D, that of coupled columns.

2608. *Fig. 897.* is a similar application of the intercolumniations to the Corinthian order, wherein also A exhibits the eustyle; B, the diastyle; and C, the aræostyle intervals: D also showing the space used of 1 module for coupled columns.

2609. Sir William Chambers, for whose observations we have much respect,—and, indeed, to whose valuable labours we acknowledge ourselves much indebted,—seems to have had a distant glimpse of the doctrine of equal weights and supports, but knew not exactly how to justify his notions on the subject. He therefore avoids the main question by attributing the pycnostyle intercolumniation rather to necessity than choice; observing, that “as the architraves were composed of single stones or blocks of marble, extending from the axis of one column to that of another, it would have been difficult to find blocks of a sufficient length for diastyle intervals in large buildings.” But this is a reason altogether unsatisfactory, inasmuch as we know that they were sufficiently

Fig. 896.

Fig. 897.

masters of masonry to have conquered any such difficulty. We are much more inclined to agree with him when he says (always, however, reverting to the principle of equal supports and weights), “With regard to the aræostyle and Tuscan intercolumniations, they are by much too wide either for beauty or strength, and can only be used in structures where the architraves are of wood, and where convenience and economy take place of all other considerations: nor is the diastyle sufficiently solid in large compositions.” These considerations, however, may be always safely referred to the doctrines laid down in Section II. of this Chapter, already alluded to; and, indeed, that reference is justified by the instructions of Vitruvius in the second chapter of his third book, wherein he directs that the thickness of the column should be augmented in an enlarged intercolumniation: as, for example, supposing the diameter of a column in the pycnostyle species to be taken one tenth of the height, it should in an aræostyle be one eighth; arguing, that if in an aræostyle the thickness of the columns exceed not a ninth or tenth part of their height, they appear too slender, and in the pycnostyle species the column at one eighth of its height is clumsy and unpleasant in appearance. Upon this passage Chambers observes, “that the intention of Vitruvius was good, but the means by which he attempts to compass it insufficient. His design was to strengthen the supports in proportion as the intervals between them were enlarged; yet according to the method proposed by him this cannot be effected, since one necessary consequence of augmenting the diameter of the column is enlarging the intercolumniation proportionably. Palladio and Scamozzi have however admitted this precept as literally just, and by their manner of applying it have been guilty of very considerable absurdity.” We are not at all inclined to admit the truth of the opinion of Chambers; for, again reverting to the doctrine of the supports and loading, which was unknown to him, it is to be remembered that increase in the space of the intercolumniation immediately involves increase of weight in the load or entablature, and therefore seems to demand increase of diameter to the supports. Palladio and Scamozzi were not therefore guilty of the absurdity laid to their charge.

2610. Among the other reasons for our adopting the practice of Vignola is that he has observed so much uniformity in his intercolumniations, except of the Doric order, wherein the triglyphs prevent it, aware as we are that the practice has by many able writers been much condemned. Chambers even says that his practice in this respect is “preferable to any other, as it answers perfectly the intention of Vitruvius, preserves the character of each order, and maintains in all of them an equal degree of real solidity.”

2611. With the exception of the Doric order, wherein the most perfect arrangement of the detail results from the interval produced by the ditriglyph, there can be no doubt that, abstractedly considered, the diastyle and eustyle intercolumniations are very convenient in use, and may be employed on most occasions, except, as just mentioned, in the Doric order.

2612. In setting out the intervals between columns especial care must be taken that the centres of modillions, dentils, and other ornaments in the entablature fall over the axes of the columns. It is on this account that Vignola gives about two diameters and a third to the intervals in all the orders except the Doric, instead of two diameters and a quarter, as required by Vitruvius; an alteration which removes the difficulty and greatly simplifies the rules.

2613. Cases from many circumstances often occur where greater intercolumniations than the eustyle and diastyle are too narrow for use, and the moderns, headed by Perrault, have adopted an interval which that master has called *aræostyle*. This disposition is obtained without infringing on the law of weights and supports, to which we have already so often alluded. In it the columns are *coupled*, as shown in the preceding figures, the interval being formed by two systyle intercolumniations, the column separating them being, as Chambers observes, "approached towards one of those at the extremities, sufficient room being only left between them for the projection of the capitals, so that the great space is  $3\frac{1}{2}$  diameters wide, and the small one only half a diameter." One of the finest examples of this practice is to be seen in the façade of the Louvre, (see *fig.* 176.) which in many respects must be considered as the finest of modern buildings. The objections of Blondel to the practice are not without some weight, but the principal one is the extra expense incurred by it; for certain it is that it requires nearly double the number of columns wanted in the diastyle, besides which it cannot be denied that it causes considerable irregularities in the entablatures of the Doric, Corinthian, and Composite orders, which, however, are not apparent in the other two. It is, nevertheless, so useful in cases of difficulty which constantly arise, that we should be sorry to exclude the practice altogether, though we cannot recommend it for unlimited adoption.

2614. A great many expedients have been employed to obviate the irregularity of the modillions in the Corinthian and Composite orders, arising from the grouping of columns. We, on this head, agree with Chambers, whose instructions we subjoin in his own words: "The simplest and best manner of proceeding is to observe a regular distribution in the entablature, without any alteration in its measures, beginning at the two extremities of the building, by which method the modillions will answer to the middle of every other column, and be so near the middle of the intermediate ones, that the difference will not easily be perceivable. The only inconvenience arising from this practice is, that the three central intercolumniations of the composition will be broader by one third of a module than is necessary for eleven modillions: but this is a very trifling difference, easily divided and rendered imperceptible if the extent be anything considerable." In the Doric order, the grouping of columns is not so easily managed, and therein our author recommends the expedient employed by Palladio, in the Palazzo Chiericato, and in the Basilica at Vicenza. In the last-named, the coupled columns are only 21 minutes apart, thus making the space between the axes 2 modules and 21 minutes, that is, 6 minutes beyond the breadth of a regular metope, and 2 half-triglyphs. To conceal the excess, the triglyphs are 31 minutes broad, and their centres are carried 1 minute within the axis of the column, and the metope is 3 minutes broader than the others. These small differences are not perceptible without a very critical and close examination of the distribution. In this arrangement the attic base of Palladio should be employed, because of its small projection, and the larger intercolumniation must be *aræostyle*.

2615. Intercolumniations should be preserved of equal width in all peristyles, galleries, porticoes, and the like; but in loggias or porches, the middle interval may be wider than the others by a triglyph, a modillion or two, and a few dentils, that is, if there be no coupled columns at the angles nor groupings with pilasters, in which cases all the other intervals should be of the same dimensions. It has been observed by Blondel, that on occasions where several rows of columns are used, as, for instance, in the curved colonnades of the piazza of St. Peter's, the columns ought as much as possible to be in straight lines, because otherwise the arrangement can only be understood by viewing it from the centre of the figure employed. The observation is well worth the student's consideration, for the resulting effect of a departure from this rule, as Chambers has properly observed, is "nothing but confusion to the spectator's eye from every point of view." The same author condemns, and with justice, though in a smaller degree, the use of "engaged pilasters or half columns placed behind the detached columns of single, circular, oval, or polygonal peristyles, as may be seen in those of Burlington House. Wherefore," he says, "in buildings of that kind, it will perhaps be best to decorate the back wall of the peristyle with windows or niches only." We can hardly suppose it here necessary to caution the student against the use of intercolumniations without reference to the absolute

size of them : they must not be less than three feet even in small buildings, because, as Sir William Chambers seriously says, "there is not room for a *fat* person to pass between them."

2616. Before leaving the subject which has furnished the preceding remarks on intercolumniations, we most earnestly recommend to the student the re-perusal of Section II. of this Book. The intervals between the columns have, in this section, been considered more with regard to the laws resulting from the distribution of the subordinate parts, than with relation to the weights and supports, which seem to have regulated the ancient practice : but this distribution should not prevent the application generally of the principle, which may without difficulty, as we know from our own experience, be so brought to bear upon it as to produce the most satisfactory results. We may be perhaps accused of bringing a fine art under mechanical laws, and reducing refinement to rules. We regret that we cannot bind the professor by more stringent regulations. It is certain that, having in this respect carried the point to its utmost limit, there will still be ample opportunity left for him to snatch that grace, beyond the reach of art, with the neglect whereof the critics are wont so much to taunt the artist in every branch.

## SECT. X.

### ARCADES AND ARCHES.

2617. An arcade, or series of arches, is perhaps one of the most beautiful objects attached to the buildings of a city which architecture affords. The utility, moreover, of arcades in some climates, for shelter from rain and heat, is obvious ; but in this dark climate, the inconveniences resulting from the obstruction to light which they offer, seems to preclude their use in the cities of England. About public buildings, however, where the want of light is of no importance to the lower story, as in theatres, courts of law, churches, and places of public amusement, and in large country seats, their introduction is often the source of great beauty, when fitly placed.

2618. In a previous section (2524.) we have spoken of Lebrun's theory of an equality between the weights and supports in decorative architecture : we shall here return to the subject, as applied to arcades, though the analogy is not, perhaps, strictly in point, because of the dissimilarity of an arch to a straight lintel. In *fig. 898.* the hatched part AEMFDCOB is the load, and ABGH, CDIK the supports. The line GK is divided into six parts, which serve as a scale to the diagram, the opening HI being four of them, the height BH six, NO two, and OM one. From the exact quadrature of the circle being unknown, it is impossible to measure with strict accuracy the surface BOC, which is necessary for finding by subtraction the surface AEMFDCOB ; but using the common method, we have

Fig. 898.

$$AD \times AE - \frac{BC^2 \times 7854}{2} = \text{to that surface ; or, in figures,}$$

$$6 \times 3 - \frac{4 \times 4 \times 7854}{2} = 11 \cdot 72.$$

Now the supports will be  $IK \times IC \times 2$  (the two piers) = the piers ; or, in figures,

$$1 \times 6 \times 2 = 12 \cdot 00.$$

That is, in the diagram the load is very nearly equal to the supports, and would have been found quite so, if we could have more accurately measured the circle, or had with greater nicety constructed it. But we have here, where strict mathematical precision is not our object, a sufficient ground for the observations which follow, and which, if not founded on something more than speculation, form a series of very singular accidents. We have chosen to illustrate the matter by an investigation of the examples of arcades by Vignola, because we have thought his orders and arcades of a higher finish than those of any other master ; but testing the hypothesis, which we intend to carry out by examples from Palladio, Scamozzi, and the other great masters of our art, not contemplated by Lebrun, the small differences, instead of throwing a doubt upon, seem to confirm it.

2619. In *fig. 898.* we will now carry, therefore, the consideration of the weights and supports a step further than Lebrun, by comparing them with the void space they surround, that is, the opening HBOCI ; and here we have the rectangle HBCI = HB  $\times$  HI, that is,  $6 \times 4 = 24$ , and the semicircle BOC equal, as above, to  $\frac{4 \times 4 \times 7854}{2} = 6 \cdot 28$ . Then  $24 + 6 \cdot 28 = 30 \cdot 28$  is the area of the whole void, and the weight and support being  $11 \cdot 72 +$

12=23.72, are a little more than two thirds the areas of the whole void ; a proportion which, if we are to rely on the approval of ages in its application, will be found near the limits of what is beautiful.

2620. We shall now refer to the examples of Vignola alluded to ; but to save the repetition of figures in their numbers, as referred to, each case is supposed in what immediately follows as unconnected with the entablatures which they exhibit, it being our intention to take those into separate consideration.

Fig. 899.

Fig. 900.

2621. Suppose the Tuscan example (*fig. 899.*) without an entablature, we have the

$$\begin{array}{rcl}
 \text{Supports, } 9.75 \times 3 & = & 29.25 \\
 \text{The whole of rectangle above them, } 4.25 \times 9.5 & = & 40.375 \\
 \text{Less semi-arch, } \frac{6.5 \times 6.5 \times 7854}{2} & = & 16.6 \\
 \hline
 & & 23.775 \\
 & & \text{53.025 solid parts.}
 \end{array}$$

The area of the void is  $16.6 + 9.75 \times 6.5 = 79.97$ , whereof 53.025, the portion of solid parts, is not widely different from two thirds.

In Vignola's Doric example, (*fig. 900.*), again without the entablature, we have

$$\begin{array}{rcl}
 \text{Supports, } 10.5 \times 3 & = & 31.50 \\
 \text{The whole rectangle above them, } 5.5 \times 10.0 & = & 55.00 \\
 \text{Less semi-arch, } \frac{7 \times 7 \times 7854}{2} & = & 19.24 \\
 \hline
 & & 35.76 \\
 & & \text{67.26 solid parts.}
 \end{array}$$

The area of the void is  $19.24 + 10.5 \times 7 = 92.74$ , whereof 67.26, the portion of solid parts, is not much different from two-thirds.

In the Ionic example (*fig. 901.*), still without considering the entablature, the following will result : —

$$\begin{array}{rcl}
 \text{Supports, } 12.64 \times 2.66 & = & 33.61 \\
 \text{The whole rectangle above them, } 10.88 \times 5.2 & = & 56.57 \\
 \text{Less semi-arch, } \frac{6.4 \times 6.4 \times 7854}{2} & = & 16.08 \\
 \hline
 & & 40.49 \\
 & & \text{74.10 solid parts.}
 \end{array}$$

The area of the void is  $16.08 + 12.64 \times 7.1 = 105.82$ , whereof 74.10, the portion of solid parts, differs little in amount from two thirds of the void.

Fig. 901.

Fig. 902.

In the Corinthian example (*fig. 902.*), not taking into consideration the entablature, the following is the result :—

$$\begin{array}{rcl}
 \text{Supports, } 14 \cdot 11 \times 3 \cdot 55 & = & 50 \cdot 09 \\
 \text{The whole rectangle above them, } 11 \cdot 33 \times 5 \cdot 88 & = & 66 \cdot 62 \\
 \text{Less semi-arch, } \frac{7 \cdot 76 \times 7 \cdot 76 \times 7854}{2} & = & 23 \cdot 65 \\
 & = & 32 \cdot 97 \\
 & = & 83 \cdot 06 \text{ solid parts.}
 \end{array}$$

The area of the void is  $23 \cdot 65 + 14 \cdot 11 \times 7 \cdot 76 = 133 \cdot 15$ , whereof  $83 \cdot 06$ , the portion of solid parts, is somewhat less than two thirds of the void.

2622. The result which flows from the above examination seems to be that, without respect to the entablature, the ratio of the solid part to that of the void is about  $\cdot 666$ . Bearing this in mind, we shall next investigate the ratio of the supports and weights, considering the entablature above the arcade as a part of the composition; and still following Vignola, whose examples, as we have above stated, do not so much differ from those of other masters as to make it necessary to examine those of each, we will begin with that architect's Tuscan arcade, without pedestals, exhibited in *fig. 899.* on the preceding page. In this example, from centre to centre of pier,

$$\begin{array}{rcl}
 \text{The whole area, in round numbers, } 17 \cdot 5 \times 9 \cdot 5 & - & - & = 166 \cdot 2 \\
 \text{Area of semi-arch, } \frac{6 \cdot 5 \times 6 \cdot 5 \times 7854}{2} & - & - & = 16 \cdot 6 \\
 \text{Rectangle under it, } 9 \cdot 75 \times 6 \cdot 5 & - & - & = 63 \cdot 3 \\
 \text{Total void, therefore,} & & & = 79 \cdot 9
 \end{array}$$

$$\begin{array}{rcl}
 \text{Entablature, } 9 \cdot 5 \times 3 \cdot 5 & - & - & = 33 \cdot 2 \\
 \text{Leaves for the supporting parts} & - & - & = 53 \cdot 1
 \end{array}$$

In this example, therefore, the supporting parts are 53, those supported 33, and the voids 79. The ratio between the solid and void parts =  $\cdot 9$ , and the ratio of the supports to the weights is  $\frac{53}{33} = \cdot 62$ .

The distance between the axes of the columns is 9 modules and 6 parts; the height of the semi-arch, 3 modules and 3 parts; and between the crown of it and the under side of the architrave is 1 module; the whole height, including entablature, being 17 modules and a half.

2623. Following the same general method, we submit the Doric arcade (*fig.* 900.) without pedestal. Measuring, as before, from centre to centre of piers,

The whole area, in round numbers, $20 \cdot 2 \times 10$	-	-	-	= 202·0
Area of semi-arch $\frac{7 \times 7 \times 7854}{2}$	-	-	-	= 19·2
Rectangle under it, $10 \cdot 5 \times 7$	-	-	-	= 73·5
Total void, therefore, =				92·7
				109·3
Entablature, $10 \times 4 \cdot 2$	-	-	-	42·0
				67·3
Leaves for the supporting parts	-	-	-	

In this example, therefore, the supporting parts are 67, those supported 42, and the voids 92. The ratio between the solid and void parts is ·85, and the ratio of the supports to the weights is  $\frac{42}{67} = \cdot 63$ .

The distance between the axes of the columns is 10 modules, the height of the semi-arch is 3 modules and 6 parts, and between the crown of it and the underside of the architrave is 2 modules; the whole height, including the entablature, being 20 modules  $3\frac{1}{2}$  parts.

2624. The Ionic arcade, without pedestal, is shown in *fig.* 901. The measurements, as above, from centre to centre of pier,

The whole area, $22 \cdot 64 \times 10 \cdot 88$ in round numbers	-	-	-	= 246·3
Area of semi-arch, $\frac{6 \cdot 4 \times 6 \cdot 4 \times 7854}{2}$	-	-	-	= 16 1
Rectangle under it, $12 \cdot 64 \times 7 \cdot 1$	-	-	-	= 89·7
Total void, therefore, =				105·8
				140·5
Entablature, $10 \cdot 88 \times 4 \cdot 8$	-	-	-	52·2
				88·3
Leaves for the supporting parts	-	-	-	

Hence, in the example, the supporting parts are 88, those supported 52, and the voids 105; so that the ratio of the voids to the solids, in this order, is ·8, and the ratio of the supports to the weights does not materially differ from the other orders, being  $\frac{52}{88} = \cdot 6$ .

The distance between the axes of the columns is 10 modules 16 parts, the height of the semi-arch is  $3\frac{1}{2}$  modules 3 parts, and between the crown of it and the under side of the architrave is 2 modules; the whole height, including the entablature, being 22 modules  $13\frac{1}{2}$  parts.

2625. *Fig.* 902. represents the Corinthian arcade without pedestal. The measurement, as before, is from centre to centre of pier.

The whole area, $25 \cdot 2 \times 11 \cdot 33$ , in round numbers	-	-	-	= 288·5
Area of semi-arch, $\frac{7 \cdot 76 \times 7 \cdot 76 \times 7854}{2}$	=	23·6		
Rectangle under it, $14 \cdot 11 \times 7 \cdot 76$	=	109·5		
Total voids, therefore,				133·1
				155·4
Entablature, $10 \cdot 36 \times 5 \cdot 6$	-	-	-	58·0
				97·4
Leaves for the supporting parts	-	-	-	

In the Corinthian example, therefore, the supporting parts are 97, those supported 58, and the voids 133. The ratio between the solid and void parts = ·8, and the ratio of the supports to the weights  $\frac{58}{97} = \cdot 59$ . The distance between the axes of the columns is 11 modules and 6 parts, the height of the semi-arch is 3 modules 16 parts, and between the crown of it and the under side of the architrave is 2 modules  $3\frac{1}{2}$  parts; the whole height, including the entablature, being 25 modules  $3\frac{1}{2}$  parts.

2626. The laws laid down by Chambers for regulating arcades are as follow: — "The void or aperture of arches should never be much more in height nor much less than double their width; the breadth of the pier should seldom exceed two thirds, nor be less than one third of the width of the arch, according to the character of the composition, and the angular piers should be broader than the rest by one half, one third, or one fourth." . . . "The height of the impost should not be more than one seventh, nor need it ever be less than one ninth of the width of the aperture, and the archivolt must not be more than one eighth nor less than one tenth thereof. The breadth of the console or mask, which serves as a key to the arch, should at the bottom be equal to that of the archivolt, and its sides must be drawn from the centre of the arch. The length thereof ought not to be less than one and a half of its bottom breadth, nor more than double."

2627. The ratios that have been deduced by comparing the void and solid parts, if there be any reason in the considerations had, show that this law of making arches in arcades of the height of 2 diameters is not empirical, the following being the results of the use of the ratios in the arcade without, and that with pedestal, of which we shall presently treat. Thus in the

	13·5 height 6·5 width	Diameters. = 2·0; with pedestals,	17·5 9·5 = 1·84
Tuscan arcade without pedestal,	$\frac{14·0}{7}$	= 2·0	— $\frac{20·0}{10·0} = 2·00$
Doric arcade without pedestal,	$\frac{15·83}{7·10}$	= 2·2	— $\frac{22·0}{11·0} = 2·00$
Ionic arcade without pedestal,	$\frac{18·00}{7·76}$	= 2·3	— $\frac{25·0}{12·0} = 2·08$
Corinthian arcade without pedestal,			

2628. In the examples of the arcades with pedestals, we shall again repeat the process by which the results are obtained, first merely stating them in round numbers. Fig. 903. is a

Fig. 903.

Tuscan arcade from Vignola's example, as will be the following ones. In this the whole area is 306, omitting fractions, the area of the void is 156, that of the entablature 50, and the supports 100. The ratio of the supported part (the entablature), therefore, is  $\frac{50}{100} = \cdot 5$ , and the supports and weights are very nearly equal to the void. The height of the pedestal is almost 3 modules and 8 parts, the opening 9 modules 6 parts, and the width of the whole pier 4 modules and 3 parts.

The detail of the above result is as follows:—

The whole area,  $22·30 \times 13·75$  - - - - - = 306·62

Area of semi-arch,  $\frac{9·5 \times 9·5 \times 7854}{2}$  = 35·43

Below that,  $12·75 \times 9·75$  - = 121·12

Total voids, therefore, = 156·55

Entablature,  $13·75 \times 3·66$  - - - - - = 50·32

Leaves for supporting parts - - - - - 99·75

It will be seen that we have taken the numbers in the preceding paragraph without supplying strictly the decimal parts that arise from the multiplication and subtraction of the several portions compared. The coincidence of the hypothesis with the apparent law is no less remarkable in this example than it will be found in those that follow; and, sceptical as we at first were on the appearances which pointed to it, we cannot, after the examination here and hereafter given, do otherwise than express our conviction that, in carrying out the principles, no unpleasant combination can result.

Fig. 904.

2629. *Fig. 904.* exhibits the Doric arcade, whose whole area from centre to centre of columns is 374. The area of the void is 189, that of the entablature 62, and of the supporting parts 112. The ratio of the entablature to the supports is therefore  $\frac{62}{112} = .55$ , and that of the supports and weights to the voids .9. The height of the pedestal is almost 5 modules and 4 parts, the opening 10 modules, and the width of a pier 4 modules and 9 parts.

As in the preceding example, we think it will be useful to detail the process by which the general results stated have been arrived at. It is curious and interesting to observe the similarity between the cases. It is scarcely possible to believe that accident could have produced it. May not the freemasons of the middle ages have had some laws of this nature which guided their operations? But we will now proceed to the calculation.

The whole area,  $25.4 \times 14.75$  - - - - - = 374.65

Area of semi-arch,  $\frac{10.0 \times 10.0 \times .7854}{2}$  = 39.27

Below that,  $12.75 \times 9.75$  - - - - - = 150.00

Total voids, therefore, - - - - - = 189.27

185.38

Entablature,  $14.75 \times 4.25$  - - - - - = 62.68

Leaves for supporting parts - - - - - 122.70

Herein, as before, the general result in the preceding paragraph has been given in round

numbers, that the mind of the reader may not be distracted from the general proportions. The detail again corroborates the hypothesis, as in the preceding subsection was predicated, and the further we proceed, as will be presently seen, its truth becomes more manifest.

Fig. 905.

2630. The Ionic arcade with a pedestal is shown in *fig. 905*. The whole area is 448 between the axes of the columns; that of the void, 228. The entablature's area is 73, and the supporting parts 146. The ratio, therefore, of the load to the support is  $\frac{73}{146} = .5$ , and supports and weights are very nearly equal to the void. The height of the pedestal is 6 modules, the opening 11 modules, and the width of a pier 4 modules and 12 parts.

Once more returning to the detail on which the above proportions are based, and which in this as in the following example we think it better to supply, observing, as before, that the numbers above stated are given roundly, we shall have in the Ionic arcade,

Whole area, $28.66 \times 15.66$	-	-	-	-	-	= 448.81
Area of semi-arch, $\frac{11 \times 11 \times .7854}{2}$	=	47.01				
Below it, $16.5 \times 11$	-	=	181.50			
Total area of voids, therefore,						= 228.51
						220.30
Entablature, $15.66 \times 4.7$	-	-	-	-	-	= 73.50
Leaves for supporting parts	-	-	-	-	-	146.80

Whence it will be seen that the round numbers first given are shown to be sufficiently accurate for exemplification of the law, and that the further we examine the hypothesis the more closely we find it connected with the theory of weights and loads that has occupied a very considerable portion of this Book, and which we hope may not have had the effect of exhausting the reader's patience. We trust we shall have his pardon for pursuing the course we have taken.

**Fig. 906.**

2631. *Fig. 906.* is an arcade with pedestals of the Corinthian order. Its total area is 528, that of the void 284, the area of the entablature 84, and that of the supporting parts 159. Hence, the ratio of the load to the support is  $\frac{84}{284} = .52$ , and the supports and weight are equal in area to the void within a very small fraction. The height of the pedestal is  $6\frac{1}{2}$  modules, the opening is 12 modules wide, and the width of a pier is 4 modules and 9 parts.

We here close the curious proofs of a law whose existence, we believe, has never been suspected by modern architects. It was clearly unknown to Rondelet, and but for the work of Lebrun already quoted, we might never have been led to the investigation of it. That author himself, as we believe, did not entertain any notion of it.

**In the Corinthian arcade with pedestal we have**

Whole area, $32 \times 16\cdot5$	$= 528\cdot00$
Area of semi-arch, $\frac{12 \times 12 \times \cdot7854}{2}$	$= 56\cdot05$
Below it, $19 \times 12$	$= 228\cdot00$
<b>Total area of voids, therefore,</b>	<b><u><math>= 284\cdot05</math></u></b>
	<b><u><math>243\cdot95</math></u></b>
Entablature, $16\cdot5 \times 5\cdot09$	$= 84\cdot10$
Leaves for supporting parts	<u><math>159\cdot85</math></u>

Thus, again, the law seems to be borne out, and to prove that the assumptions we have been making are not those of empiricism.

2632. In *fig.* 907. are collected the impostos and archivoltos used in the arcades of the different orders.

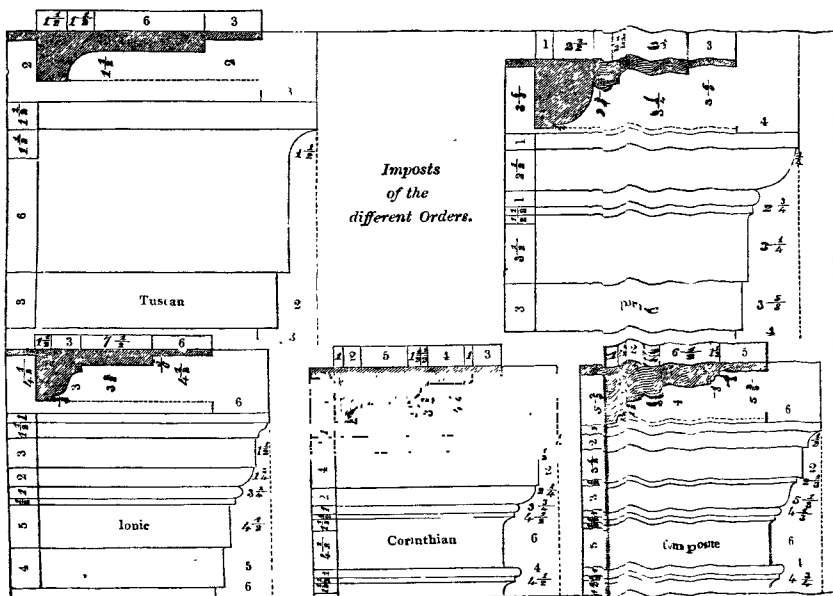

Fig. 907.

2633. We are not of the opinion of Sir William Chambers in respect of the arcades which Vignola has given; that author had not, we think, critically examined their composition, and we confess we do not think his own examples are improvements on those of the master in question; but we are willing to admit that in the example of arcades with pedestals, they would have been much improved by assigning a greater height generally to the plinths of the pedestals, which are, doubtless, much too low, and might be well augmented by adding to them a portion of the dies of the pedestals.

2634. Great as is our admiration of Palladio, we do not think it necessary to say more relative to his arcades, than that he has given only designs of arches with pedestals, and that their height is from one and two thirds to two and a half of their width. His piers are generally  $3\frac{1}{2}$  modules, except in the Composite order, wherein they are  $4\frac{1}{2}$  modules.

2635. Scamozzi makes his Tuscan arch a little less than double its width, increasing the height gradually to the Corinthian arch with pedestals to nearly twice and a half the width. He diminishes his piers as the delicacy of the order increases his Corinthian piers being only  $3\frac{1}{2}$  modules in width. We do not, however, think it necessary to dwell longer on this part of the subject, and shall close it by observing that the impost of the arch should not much vary from half a module in height, and that the width of the archivolt, which should touch the shaft of the column or pilaster in the geometrical elevation, at its springing, is necessarily prescribed by the width of pier. In setting out the column upon it. Where columns are used on piers, their projection must be such that the most prominent member of the impost should be in a line with the axis of the column on the transverse section. In Ionic, Composite, and Corinthian arcades, however, it may project a little beyond the axis of the columns, to avoid the disagreeable mutations which are otherwise rendered necessary in the capitals. Arcades should project not less than their width from the front of the wall which backs them." With regard to their interior decoration," says Chambers, "the portico may either have a flat ceiling or be arched in various manners. Where the ceiling is flat, there may be on the back of the piers, pilasters of the same kind and dimensions with the columns on their fronts; facing which pilasters there must be others like them on the back wall of the portico. Their projection as well as that of those against the back of the piers may be from one sixth to one quarter of their diameter. These pilasters may support a continued entablature, or be interrupted and running across the portico over every two pilasters to form coffers; or the architrave and frieze only may be continued, while the cornice alone is carried across the portico over the pilasters as before, and serves to form compartments in the ceiling, as is done in the vestibule of the Massini palace at Rome, and in the great stable of the King's Arms, near Charing Cross,"—no longer in existence, having been destroyed to make way on its site for the execrable mass of absurdity to which the government who sanctioned it have facetiously

given the name of National Gallery. Chambers thus continues:—"Where the portico is arched, either with a semi-circular or elliptical vault, the backs of the piers and the inner wall of the portico may be decorated with pilasters, as is above described, supporting a regular continued entablature, from a little above which the arch should take its spring, that no part of it may be hid by the projection of the cornice. The vault may be enriched with compartments of various regular figures, such as hexagons, octagons, squares, and the like, of which, and their decorations, several examples are given among the designs for ceilings." Of these we shall hereafter give figures in the proper place. "But when the vault is groined, or composed of flats, circular or domical coves, sustained on pendentives, the pilasters may be as broad as are the columns in front of the piers, but they must rise no higher than the top of the impost, the mouldings of which must finish and serve them instead of a capital, from whence the groins and pendentives are to spring, as also the bands or *arcs-doubleaux* which divide the vault."

2636. In the examples of arcades, we have followed those given by Chambers, as exhibiting a variety which may be instructive to the student, and at the same time afford hints for other combinations. *Fig. 908.* is one of the compositions of Serlio, and is an

Fig. 908.

Fig. 909.

expedient for arching in cases where columns have been provided, as in places where the use of old ones may be imposed on the architect. The larger aperture may be from  $4\frac{1}{2}$  to 5 diameters of the column in width, and in height double that dimension. The smaller opening is not to exceed two thirds of the larger one, its height being determined by that of the columns. Chambers thinks, and we agree with him, that this sort of disposition might be considerably improved by adding an architrave cornice or an entablature to the column, by omitting the rustics and by surrounding the arches with archivolts. It is not to be inferred, because this example is given, that it is inserted as one to be followed except under very peculiar circumstances. Where an arrangement of this kind is adopted, care must be used to secure the angles by artificial means.

2637. *Fig. 909.* is given from the cortile of the castle at Caprarola by Vignola, a structure which in the First Book of this work we have (346.) already mentioned. The height of the arches is somewhat more than twice their width. From the under side of the arch to the top of the cornice is one third of the height of the arch, the breadth of whose pier is equal to that of the arch, and the aperture in the pier about one third of its breadth.

2638. A composition of Bramante, executed in the garden of the Belvedere at Rome, is given at *fig. 910.* The arch in height is somewhat more than twice its width, and the

Fig. 910.

Fig. 911.

breadth of the pier equal to the opening. By dividing the latter into twelve parts we have a measure which seems to have prevailed in the mind of the architect, inasmuch as two of them will measure the parts of the pier supporting the archivolt, four the space for the two columns, two for the intervals between the niche and the columns, and four for the niche. Half the diameter of the arch measures the height of the pedestal; the columns are of the height of ten diameters, and their entablature one quarter of the height of the columns. The impost and archivolt are each equal to half a diameter of the column.

2639. *Fig. 911.* is an example whose employment is not uncommon in the designs of Palladio, and was considered by our great countryman Inigo Jones to be worthy of his imitation. The arch may be taken at about twice its width, and the pier not less than one nor more than two thirds of the width of the aperture.

Fig. 912.

Fig. 913.

2640. The example in *fig. 912.* is from the hand of Vignola, and was executed for one of the Borghese family at Mondragone, near Frascati. In it the arch is a little more in height than twice its width, and the breadth of the pier columns supporting the arch include a little less than the width of the arch itself. We are not quite satisfied in having here produced it as an example, though, compared with the following one, we scarcely know whether we should not on some accounts prefer it.

2641. The last example (*fig. 913.*) is one by that great master, Palladio, from the basilica at Vicenza. From the figure it is impossible to judge of its beauty in execution, neither can any imitation of it, unless under circumstances in every respect similar, produce the sensation with which the building itself acts on the spectator; yet in the figure it appears meagre and nothing worth. We can therefore easily account for the conduct of the critics, as they are called, who, never having seen this master's works, indulge in ignorant speculations of the pictorial effects which his compositions produce. Though not entirely agreeing with Chambers in his concluding observations on arcades and arches, we may safely transfer them to these pages. "The most beautiful proportion," he observes, "for compositions of this kind is, that the aperture of the arch be in height twice its width; that the breadth of the pier do not exceed that of the arch, nor be much less; that the small order be in height two thirds of the large columns, which height being divided into nine parts, eight of them must be for the height of the column, and the ninth for the height of the architrave cornice, two fifths of which should be for the architrave and three for the cornice. The breadth of the archivolt should be equal to the superior diameter of the small columns, and the keystone at its bottom must never exceed the same breadth."

## SECT. XI.

### ORDERS ABOVE ORDERS.

2642. Vitruvius, in the fifth chapter of his book "On the Forum and Basilica," in both which species of buildings it is well known that orders above orders were employed, thus instructs his readers:—"The upper columns are to be made one fourth less than those below" (*quarta parte minores quam inferiores sunt constituende*), "and that because the latter, being loaded with a weight, ought to be the stronger; because, also, we should follow the practice of nature, which in straight-growing trees, like the fir, cypress, and pine, makes the thickness at the root greater than it is at top, and preserves a gradual diminution throughout their height. Thus, following the example of nature, it is rightly ordered that bodies which are uppermost should be less than those below, both in respect of height and thickness." It is curious that the law thus given produces an exactly similar result to that

laid down by Scamozzi, p. 2. lib. v. cap. ii., whereon we shall have more presently to speak. Galliani, Chambers, and others have considered the above-quoted passage of Vitruvius in connection with another in chap. vii. of the same book, which treats of the portico and other parts of the theatre, wherein the author states, after giving several to this question unimportant details, "The columns on this pedestal" (that of the upper order) "are one fourth less in height" (*quartā parte minores altitudine sint*) "than the lower columns." The reader will here observe the word *altitudine* is introduced, which does not appear in the passage first quoted; and we beg him, moreover, to recollect that the last quotation relates entirely to the scene of the ancient theatre, in which liberties were then taken with strict architectural proportion as much as they are in these later days. Those who think that because Vitruvius interlarded his work with a few fables, he is therefore an author not worth consulting, as ephemeral critics have done in respect of that great master of the art, Palladio, may opine we have wasted time in this discussion; but, adopting the old maxim of Horace, "Non ego paucis offendar maculis," we shall leave them to the exposure which, with the instructed architect, their own ignorance will ultimately inflict on them, and to the enjoyment of the felicity attendant on a slight knowledge of the subject a person is in the habit of handling.

2643. We will now place before the student our own reading and explanation of the passage of Vitruvius relative to the use of orders above orders, and attempt to show what we conceive to be its real meaning. In fig. 914. the diagram exhibits an Ionic column placed above a Doric column: the entablature (which however does not belong to the consideration) being in both cases one fourth of the height of the column. Inasmuch as in our previous rules (following Vignola) it will be recollected that the module of the Doric order is subdivided into twelve, whilst that of the Ionic is subdivided into eighteen parts, we must, for the purpose of obtaining an uniformity of measures in both orders, reduce those of either to the other to obtain similar dimensions. Instead, therefore, of measuring the upper order by itself, which would not afford the comparison sought, we shall have to reduce its established measures to those of the lower one, or Doric, and this, as well as the measurement of the lower order itself, is taken in modules and decimal parts of its semidiameter. Thus, the lower order being 2 modules at its bottom diameter and 1·666 modules at its upper diameter, the mean, without descending to extreme mathematical nicety, may be taken at 1·833, which multiplied by the height, 18 modules = 32·994, the area of a section through the centre of the column. Now if the upper columns are to be the same thickness at the bottom as the lower ones are at the top, that is, 1·666 module of the lower order, their upper diameters will be 1·387 (that is, five sixths of the lower diameter), and the mean will be 1·526, which, multiplied by 16, the height, = 24·416 the area of a section down the centre of the column, and just one fourth less than that of the lower column. The investigation tends to show us that we should not lightly treat the laws laid down by Vitruvius and his followers at the revival of the arts, for we may be assured that in most cases they are not empirical, but founded on proper principles. We cannot, however, leave this point without giving another reason, which is conclusive against Chambers's construction of the passage; it is, that supposing the upper column's lower diameter to be the same or nearly so as the lower column's upper diameter, if the *fourth* part had relation to the height instead of the bulk, we should have had the absurdity in the illustration above given, of an Ionic column in the second order only six and three quarters diameters high, whilst the lower or Doric is nine diameters in height.

Fig. 914.

2644. Scamozzi, we doubt not, thought as we have expressed ourselves on this subject, and we here translate the words he uses in the eleventh chapter of his sixth book (second part). "Hence it is more satisfactory, and they succeed better and are more pleasing to the eye, when these columns (the upper ones) are made according to their proper diminution, so that the lower part of the upper column may be just the thickness of the upper part of the lower one, and so from one to the other, as may be seen in the Ionic order of the Theatre of Marcellus and other edifices; and this is the reason and natural cause that it is the same as though out of a long and single tree the shafts were cut out one after the other."

2645. The laws of solidity seem to require that where more than one order is used, the strongest is to occupy the lower situation; thus the Doric is placed on the Tuscan, the Ionic on the Doric, the Corinthian on the Ionic, and the Composite on the Corinthian; though, with respect to the last, we find examples of importance wherein the reverse has been the case. Two tiers of columns should not be of the same order, neither should an intermediate order be omitted; such, for instance, as placing the Ionic on the Tuscan column, or the Corinthian on the Doric; for by this practice many irregularities are introduced, especially in the details of the members.

2646. Frontwise the axes of the upper and lower columns must be in the same vertical plane, but viewed in flank this is not absolutely necessary; they should not, however, deviate too much from it. In the theatre of Marcellus the axes of the upper columns are nearly a foot within those of the Doric below them; but circumstances required this, and there is no great objection to the practice if the solidity of the structure be not lessened by it. Chambers observes that the retraction should never be greater than at the theatre of Marcellus, where the front of the plinth in the second order is in a line with the top of the shaft in the first. When the columns are detached, they should be placed centrally over each other, so that the axes of the upper and under ones may form one continued line, by which means solidity is gained as well as a satisfactory result to the eye. As to the false bearings of the bases of the upper order on the profile, this is a matter neither really affecting stability nor the appearance of the design.

2647. In England there are not many examples of orders above orders, while on the Continent the practice has not been uncommon; but it is always a matter of great difficulty so to arrange them as to avoid irregularities where triglyphs and modillions in the same design meet in the composition. We have used the figures of Chambers for our illustration here, because they are nearly coincident with the rules of Vitruvius and Scamozzi, and we shall now place them before the reader, observing that the irregularities alluded to are almost altogether avoided.

Fig. 915.

Fig. 916.

2648. *Fig. 915.* exhibits the Doric over the Tuscan order. The intervals A, B, and C are respectively  $2\frac{1}{2}$ , 4, and  $6\frac{1}{2}$  modules; and A', B', and C', 3,  $5\frac{1}{2}$ , and 8 modules of their order. The entablature of the lower order is  $3\frac{1}{2}$  modules, the column, including base and capital, being 14 modules high; and the entablature of the upper order is 4 modules high, the column with its base and capital being 16 modules in height.

2649. The distribution of the Doric and Ionic orders is given in *fig. 916.*, wherein the intervals A, B, and C are respectively 3,  $5\frac{1}{2}$ , and 8 modules; D, 7 module; and A', B', C', and D' respectively 4, 7, 10, and  $1\frac{1}{2}$  modules. The Doric order in this example is 20 modules high, whereof 4 are assigned to the entablature; the Ionic 22 modules high, whereof 4 belong to the entablature.

2650. In *fig. 917.* is represented the Corinthian above the Ionic order; the intervals A, B, C, D are respectively 5, 6, 7, and 1 modules, and those of A', B', C', D' respectively  $6\frac{1}{4}$ ,  $7\frac{1}{6}$ ,  $8\frac{1}{8}$ ,  $1\frac{1}{6}$  modules; the lower order is  $22\frac{1}{2}$  modules high, 18 being given to the column with its base and capital; and the upper or Corinthian order is  $24\frac{1}{2}$  modules high, whereof 20 belong to the height of the column, including its base and capital.

2651. The last (*fig. 918.*) is of the Corinthian order above and Composite below. In the lower order the intervals A, B, C, D are  $4\frac{3}{4}$ , 6, 7, and 1 modules respectively, and A', B', C', and D', in the upper order, 6,  $7\frac{1}{6}$ ,  $8\frac{1}{8}$ , and  $1\frac{1}{6}$  modules respectively. The whole height of the Corinthian order is 25 modules, whereof 5 are given to the entablature; the Composite order here is  $24\frac{1}{2}$  modules, of which 20 belong to the column, including the base and capital.

2652. We insert the observations of Chambers relative to the above four figures, which,

Fig. 917.

Fig. 918.

as we have adopted them, shall be in his own words. "Among the intercolumniations there are some in the second orders extremely wide, such as the Ionic interval over the Doric aræostyle; the Composite and Corinthian intervals over the Ionic and Composite aræostyle, which, having a weak meagre appearance, and not being sufficiently solid, excepting in small buildings, are seldom to be suffered, and should seldom be introduced. The most eligible are the eustyle and diastyle for the first order, which produce nearly the diastyle and aræostyle in the second." Speaking of the use of pedestals in orders above orders, the author thus proceeds:—"Many architects, among which number are Palladio and Scamozzi, place the second order of columns on a pedestal. In compositions consisting of two stories of arcades this cannot be avoided, but in colonnades it may and ought; for the addition of the pedestal renders the upper ordonnance too predominant, and the projection of the pedestal's base is both disagreeable to the eye and much too heavy a load on the inferior entablature. Palladio, in the Barbarano palace at Vicenza, has placed the columns of the second story on a plinth only, and this disposition is best; the height of the plinth being regulated by the point of view, and made sufficient to expose to sight the whole base of the column. In this case the balustrade must be without either pedestals or half balusters to support its extremities, because these would contract and alter the form of the column; its rail or cap must be fixed to the shafts of the columns, and its base made level with their bases; the upper torus and fillet of the columns being continued in the interval, and serving as mouldings to the base of the balustrade. The rail and balusters must not be clumsy; wherefore it is best to use double-bellied balusters, as Palladio has done in most of his buildings, and to give the rail a very little projection, that so it may not advance too far upon the surface of the column, and seem to cut into it. In large buildings the centre of the baluster may be in a line with the axis of the column; but in small ones it must be within it, for the reason just mentioned. The height of the balustrade is regulated in a great measure by its use, and cannot well be lower than three feet, nor should it be higher than three and a half or four feet. Nevertheless, it must necessarily bear some proportion to the rest of the architecture, and have nearly the same relation to the lower order, or whatever it immediately stands upon, as when a balustrade is placed thereon chiefly for ornament. Wherefore, if the parts are large, the height of the balustrade must be augmented, and if they are small it must be diminished; as is done in the Casino at Wilton, where it is only two feet four inches high, which was the largest dimension that could be given to it in so small a building. But that it might, notwithstanding its lowness, answer the intended purpose, the pavement of the portico is six inches lower than the bases of the columns, and on a level with the bottom of the plat-band that finishes the basement."

We must here leave this subject, recommending the student to an intimate acquaintance with the various examples that have been executed, and further advising him to test each of the examples that may fall under his notice by the principles first adverted to in this section, as the only true means of arriving at a satisfactory result.

## SECT. XII.

## ARCADES ABOVE ARCADES.

2653. As the disposition of one arcade upon another is, under certain regulations, subject to the same laws of voids and solids as the simple arcade of one story, which has formed the subject of a previous section, we shall no further enter into the rules of its combination than to offer a few general observations on the matter in question; and herein, even with the reproach of a want of originality, we shall draw largely on our much-quoted author, Chambers, whose language and figures we are about to use. So sound, indeed, is the doctrine of Chambers in this respect, and so well founded on what has been done by those whom we consider the greatest masters, that we should not be satisfied without transferring his dicta to these pages, and that without any alteration.

2654. "The best," says Chambers, "and, indeed, the only good disposition for two stories of arcades, is to raise the inferior order on a plinth, and the superior one on a pedestal, as Sangallo has done at the Palazzo Farnese; making both the ordonnances of an equal height, as Palladio has done at the Basilica of Vicenza."

2655. "Scamozzi, in the thirteenth chapter of his sixth book, says that the arches in the second story should not only be lower, but should also be narrower, than those in the first; supporting his doctrine by several specious arguments, and by the practice, as he says, of the ancient architects in various buildings mentioned by him. In most of these, however, the superior arches are so far from being narrower, that they are either equal to or wider than the inferior ones. In fact, his doctrine in this particular is very erroneous, entirely contrary to reason, and productive of several bad consequences; for if the upper arches be narrower than the lower ones, the piers must of course be broader, which is opposite to all rules of solidity whatever, and exceedingly unsightly. The extraordinary breadth of the pier on each side of the columns in the superior order is likewise a great deformity; even when the arches are of equal widths it is much too considerable. Palladio has, in the *Carità* at Venice, and at the Palazzo Thiene in Vicenza, made his upper arches wider than the lower ones, and I have not hesitated to follow his example; as by that means the weight of the solid in the superior order is somewhat diminished, the fronts of the upper piers bear a good proportion to their respective columns, and likewise to the rest of the composition."

2656. "In a second story of arcades there is no avoiding pedestals. Palladio has, indeed, omitted them at the *Carità*, but his arches there are very ill proportioned. The extraordinary bulk and projection of these pedestals are, as before observed, a considerable defect; to remedy which in some measure they have been frequently employed without bases, as in the theatre of Marcellus, on the outside of the Palazzo Thiene, and that of the Chiericato in Vicenza. This, however, helps the matter but little; and it will be best to make them always with bases of a moderate projection, observing at the same time to reduce the projection of the bases of the columns to ten minutes only, that the die may be no larger than is absolutely necessary; and in this case particular care must be taken not to break the entablature over each column of the inferior order, because the false bearing of the pedestal in the second order will by so doing be rendered far more striking, and in reality more defective, having then no other support than the projecting mouldings of the inferior cornice. There is no occasion to raise the pedestals of the second order on a plinth, for as they come very forward on the cornice of the first order, and as the point of view must necessarily be distant, a very small part only of their bases will be hid from the eye."

2657. "The balustrade must be level with the pedestals supporting the columns; its rail or cornice and base must be of equal dimensions, and of the same profile with theirs. It should be contained in the arch and set as far back as possible, that the form of the arch may appear distinct and uninterrupted from top to bottom; for which reason, likewise, the cornice of the pedestals must not return nor profile round the piers, which are to be contained in straight perpendicular lines from the impostes to the bases of the pedestals. The back of the rail may either be made plain or sunk into a panel in form of an open surbase, for so it will be most convenient to lean upon, and it should be in a line with or somewhat recessed within the backs of the piers. The back part of the balustrade may be adorned with the same mouldings as the bases of the piers, provided they have not much projection; but if that should be considerable, it will be best to use only a plinth crowned with the two upper mouldings, that so the approach may remain the more free."

2658. In *fig. 919.* is a Doric above a Tuscan arcade, from the example given by Chambers, whereon, before giving the dimensions of the different parts, we shall merely observe of it that the voids or arcades themselves are in round numbers to the solids as 295 to 205, being vastly greater. We are inclined to think that the voids in this case are rather too great in volume, and that, had they been reduced to one half their height exactly, the

proportions would have been somewhat more pleasing. It is true that a trifling irregularity would have been introduced into the triglyphs of the upper order, or rather the metopæ between them; but that might have been easily provided against by a very trifling alteration in the height of the frieze itself. This fault of making the voids too large pervades Chambers's examples, and but that we might have been thought too presuming we should have slightly altered the proportions, little being requisite to bring them under the laws which we have thought to be founded on reason and analogy. We have indeed throughout this work refrained from giving other than approved examples, preferring to confine ourselves to observations on them when we have not considered them faultless.

2659. In the figure the clear width of the lower arcade is  $7\frac{3}{4}$ , and its height  $14\frac{1}{2}$  modules. The width of each pier is 1 module. Of the upper arcade the width is  $9\frac{1}{2}$ , and the height  $18\cdot233$  modules. The width of the piers is  $1\frac{1}{2}$  module each. The height of the plinth of the lower order is  $1\frac{1}{2}$  module, that of the column, including base and capital,  $14\frac{1}{2}$  modules, the entablature  $3\frac{1}{2}$ . The height of the pedestal of the upper order is  $3\cdot733$  modules, of the column with its base and capital 16, and of the entablature  $3\cdot733$  modules. In the proportions between the voids and solids above taken the balustrade is not considered as a solid, because, in fact, it is nothing more than a railing for the protection of those using the upper story. As we have expressed our desire to give the examples of others rather than our own, we feel bound to recommend the student

to set up the diagram in question, with the simple alteration of reducing the solids nearly to an equality with the voids, which may be done with sufficient accuracy by assigning to the lower arcade a module less in width than Chambers has done; and we venture to say that he will be surprised at the difference, as regards grace and elegance, which will result from the experiment. It is to be understood that no change is proposed in the other dimensions of the ordonnance, the width of piers, orders, entablatures, all remaining untouched.

2660. In *fig. 920.* we give another example from Chambers, which, in our opinion, requires a rectification to bring it into proper form. Herein the Ionic is used above the Doric arcade, and the voids to the solids are as  $3\cdot33$  to  $2\cdot98$ , being much more than equal to them. In this, as in the former example, we should have preferred a greater equality between the solids and voids, though in that under consideration there is a nearer approximation to it.

2661. In the figure the clear width of the lower arch is  $8\frac{1}{2}$ , and its height  $16\frac{1}{2}$  modules; the width of each pier is 1 module. Of the upper arcade the width is  $10\frac{1}{2}$ , and the height  $20\frac{1}{2}$  modules. The width of the piers is  $1\frac{1}{2}$  module each. The height of the plinth of the lower order is  $1\frac{1}{2}$  module that of the column, including the base and capital,  $16\frac{1}{2}$  modules, and of the entablature 4 modules. The height of the pedestal of the upper order 4 modules, of the column, including base and capital, 18 modules, and of the entablature 4, and of the balustrade above it  $3\frac{1}{2}$ .

2662. The dimensions of the Ionic and Corinthian arcades in *fig. 921.* are as follow: — Clear width of lower arch 9 modules, its height  $18\frac{1}{2}$  modules. The width of each pier is 1 module. Of the upper arcade the width of an arch  $15\frac{3}{4}$  modules, and its height 23 modules. The width of

Fig. 919.

Fig. 920.

Fig. 921.

the piers is  $1\frac{1}{4}$  module each. The height of the plinth to the lower order is  $1\frac{3}{8}$  module; of the column, including base and capital, 18 modules; the entablature  $4\frac{1}{4}$  modules. The pedestal of the upper order is  $4\frac{1}{4}$  modules high; column, including base and capital, 20 modules; entablature  $4\frac{1}{4}$  modules; and, lastly, the balustrade is  $3\frac{3}{8}$  modules in height.

2663. *Fig. 922.* is an arrangement adopted by Palladio in his basilica at Vicenza, being the dimensions, or nearly, of the arcades on the flanks. The intermediate ones are much wider. In the basilica, however, the entablature breaks round the columns of the orders. The width between the axes of the columns of the lower order is 15 of their modules. The arch is 15 modules high and  $7\frac{5}{8}$  wide. The order wherefrom the arch springs is  $10\frac{3}{8}$  modules high; from axis to axis of the small columns in the lower arcade is 9 modules. The height of the plinth is  $1\frac{1}{2}$  module, of the principal columns, including bases and plinths, 16 $\frac{1}{2}$  modules, and of their entablature 4 modules. In the upper arcade the distance between the axes of the principal columns is 18 of their modules. Their pedestals are 4 modules high, the columns, including bases and capitals, 18 modules, and entablature 4 modules high. The width of the arch is  $9\frac{3}{8}$  modules, and its height  $20\frac{3}{8}$  modules. The height of the small columns is  $11\cdot733$  modules high, including their entablature.

2664. The use of arcades above arcades seems from its nature almost confined to public buildings, as among the ancients to their theatres and amphitheatres. In the interior quadrangles or courts of palaces they have been much employed on the Continent, and in the magnificent design made by Inigo Jones for the palace at Whitehall are to be found some very fine examples.

Fig. 922.

employed on the Continent, the palace at Whitehall are to

## SECT. XIII.

### BASEMENTS AND ATTICS.

2665. When the order used for decorating the façade of a building is placed in the middle or second story, it is seated on a story called the *basement*. The proportion of its height to the rest must in a great measure depend on the use to which its apartments are to be appropriated. "In Italy," observes Chambers, "where their summer habitations are very frequently on that floor, the basements are sometimes very high. At the palace of Porti, in Vicenza, the height is equal to that of the order placed thereupon; and at the Thiene, in the same city, its height exceeds two thirds of that of the order, although it be almost of a sufficient elevation to contain two stories; but at the Villa Capra, and at the Loco Arsieri, both near Vicenza, the basement is only half the height of the order; because in both these the ground floor consists of nothing but offices." It may hence be gathered that no absolute law can be laid down in reference to the height of a basement story. Yet we may state, generally, that a basement should not be higher than the order it is to support, for it would in that case detract from the principal part of the composition, and, in fact, would be likely to interfere with it. Besides which, the principal staircase then requires so many steps that space is wasted for their reception. "Neither," says Chambers, "should a basement be lower than half the height of the order, if it is to contain apartments, and consequently have windows and entrances into it; for whenever that is the case the rooms will be low, the windows and doors very ill formed, or not proportional to the rest of the composition, as is observable at Holkham: but if the only use of the basement be to raise the ground floor, it need not exceed three, four, or at the most five or six feet in height, and be in the form of a continued pedestal."

2666. Basement stories are decorated generally with rustic work of such various kinds, that we fear it would be here impossible to describe or represent their varieties. Many are capriciously rock-worked on their surface, others are plain, that is, with a smooth surface. The height of each course, including the joints, should on no account be less than one module of the order which the basement supports; their length may be from once and a half to thrice their height. As respects the joints, these may be square or chamfered off. When square joints are used, they should not be wider than one eighth part of the

height of the rustic itself, nor narrower than one-tenth; their depth not exceeding their width. When the joints are chamfered, the chamfer should be at an angle of forty-five degrees, and the whole width of the joint from one third to one fourth of the height of the rustic.

2667. The courses are sometimes (often on the Continent) laid without showing vertical joints; but, as Chambers says, this "has in general a bad appearance, and strikes as if the building were composed of boards rather than of stone. Palladio's method seems far preferable, who, in imitation of the ancients, always marked both the vertical and the horizontal joints; and whenever the former of these are regularly and artfully disposed, the rustic work has a very beautiful appearance." We shall presently make a few remarks on the subject of rustics; but here, to continue and finish that more immediately under consideration, have to add, that when a high basement is used, it is not uncommon to crown it with a cornice, as may be seen in *fig.* 909.; but the more common practice is to use a plat-band only (as in *fig.* 911.), whose height should not be greater than that of a rustic exclusive of the joint. Of a similar height should be made the zoccolo or plinth; but this may, and ought, perhaps, to be somewhat higher. When arches occur in basements, the plat-band, which serves for the impost, should be as high as a course of rustics, exclusive of the joint; and if the basement be finished with a cornice, such basement should have a regularly moulded base at its foot; the former to be about one thirteenth of the whole height of the basement, and the base about one eighteenth, without the plinth.

2668. The Attic — which is used instead of a second order where limits are prescribed to the height of a building, examples whereof may be seen at Greenwich Hospital, and in the Valmarano palace, by the great Palladio, at Vicenza — should not exceed in height one-third of the order whereon they are placed, neither ought they to be less than one quarter. Bearing some resemblance to a pedestal, the base, die, and cornice whereof they are composed may be proportioned much in the same way as the respective divisions of their prototypes. They are sometimes continued without, and sometimes with, breaks over the column or pilaster of the order which they crown. If they are formed with pilasters, such ought to be of the same width as the upper diameter of the order under them, never more. In projection they should be one quarter of their width at most. They may be decorated with sunk moulded panels if necessary; but this is a practice rather to be avoided, as is most especially that of using capitals to them — a practice much in vogue in France under Louis XV.

2669. We now return to the subject of the rock-worked rustic, whereof, above, some notice was promised. The practice, though occasionally used by the Romans, seems to have had its chief origin in Florence, where, as we have in a former Book (329.) observed, each palace resembled rather a fortification than a private dwelling. Here it was used to excess; and if variety in the practice is the desire of the student, the buildings of that city will furnish him with an almost infinite number of examples. The introduction of it gives a boldness and an expression of solidity to the rustics of a basement which no other means afford. In the other parts of Italy it was sparingly applied, but with more taste. Vignola and Palladio seem to have treated it as an accident productive of great variety rather than as a means of decoration. The last-named architect has in the Palazzo Thiene carried it to the utmost extent whereof it is susceptible. Yet, with this extreme extent of application, the design falls from his hands full of grace and feeling. To imitate it would be a dangerous experiment. De Brosse failed at the Luxembourg, and produced an example of clumsiness which in the Palazzo Pitti does not strike the spectator.

2670. Rustics and rockwork on columns are rarely justifiable except for the purpose of some particular picturesque effect which demands their prominence in the scene, or street view, as in the gateway at Burlington House in Piccadilly, — a splendid monument of the great talent of Lord Burlington.

#### SECT. XIV.

##### PILASTERS.

2671. Pilasters, or square columns, were by the Romans termed *antæ*, by the Greeks *parastatæ*. This last word implies the placing one object standing against another, a sufficiently good definition of the word, inasmuch as in ninety-nine cases out of a hundred they are engaged in or backed against a wall, or, in other words, are portions of square columns projecting from a wall.

2672. It is usual to call a square column, when altogether disengaged from the wall, a *pillar* or *pier*; and we are inclined to think, notwithstanding the alleged type of trees, that the primitive supports of stone buildings were quite as likely to have been square

as round, and that the inconvenience attendant upon square angles may have led the earliest builders to round off the corners, and gradually to bring them to a circular plan. Isolated pillars are rarely found among the examples left us by the ancients; the little temple at Trevi furnishes, indeed, an example, but not of the best period of the art. The principal points to be attended to in their use are their projection, diminution, the mode of uniting the entablature over them with that of their columns, and their flutings and capitals.

2673. In respect of the projection of pilasters, Perrault says they should project one half, and not exceed that by more than a sixth, as in the frontispiece of Nero, unless circumstances require a different projection. The pilasters of the Pantheon project only a tenth part of their width; and sometimes, as in the forum of Nerva, they are only a fourteenth part. But when pilasters are to receive the imposts of arches against their sides, they are made to project a fourth part of their diameter; and this is a convenient proportion, because in the Corinthian order the capital is not so much disfigured. Hence, when pilasters are made to form re-entering angles, they should project more than half their diameter. Many and various opinions have been formed on the propriety of diminishing pilasters. Perrault, with whom we incline to agree, thinks that when one face only projects, pilasters should not be diminished. Those at the flanks of the portico of the Pantheon are without diminution. But when pilasters are on the same line as columns, we want to lay the entablature from one to the other without any projection, in which case the pilaster must be diminished in the same degree as the column itself, speaking of the front face, leaving the sides undiminished, as in the temple of Antoninus and Faustina. When the pilaster has two of its faces projecting from the wall, being on the angle, and one of those faces answers to a column, such face is diminished similarly to the column, as in the portico of Septimius, where the face not corresponding to the column receives no diminution. There are, however, ancient examples where no diminution is practised, as in the interior of the Pantheon, where it is so small as not to be very apparent, being much less than that of the column, as is also the case in the temple of Mars Ultor, and in the arch of Constantine. In these cases, the custom of the ancients is sometimes to place the architrave plumb over the column, which brings it within the line of the pilaster. This may be seen in the temple of Mars Ultor, in the interior of the Pantheon, and in the portico of Septimius. Sometimes this excess is divided into two parts, one whereof goes to the excess of projection of the architrave above the column, and the other half to the deficiency of extent above the pilaster, as in the forum of Nerva. The whole matter is a problem of difficult solution, which Chambers has avoided, but which, with reference to the examples we have cited, will not be attended with difficulty to the student in his practice.

2674. We have above seen that pilasters, when used with columns, are subject to the form and conditions of the latter. As to their flutings we are left more at liberty. In the portico of the Pantheon we find the pilasters fluted and the columns plain. This, however, may have been caused by the difficulty of fluting the latter, which are of granite, whilst the pilasters are of marble. On the other hand, we sometimes find the columns fluted and the pilasters plain, as in the temple of Mars Ultor, and the portico of Septimius Severus. Generally, too, it may be observed that when pilasters project less than half their diameter, their return faces are not fluted. In respect of the number of the flutes, if the examples of the ancients were any guide, there could have been no fixed rule; for in the portico of the Pantheon, the arch of Septimius Severus, and that of Constantine, seven flutes only are cut on the pilasters, whilst the flutes of the pilasters in the interior of the Pantheon are nine in number. This, however, is to be observed, that the flutes must always be of an odd number, except in re-entering pilasters, wherein four are placed instead of three and a half, and five instead of four and a half, when the whole pilaster would have nine. This is done to prevent the ill effect which would be produced in the capital by the bad falling of the leaves over the flutes.

2675. We shall hereafter give from Chambers some representations of pilaster capitals, which, except as regards their width, resemble those of the order they accompany. The practice of the ancients in this respect was very varied. Among the Greeks the form of the pilaster capital was altogether different from that of the column, seeming to have no relationship to it whatever; but on this point the student must consult the works on Grecian antiquities, an example whereof will be found in *fig.* 883.

2676. A pilaster may be supposed to represent a column and to take its place under many circumstances; and, notwithstanding all that was said on the subject by the Abbé Laugier, many years ago, against the employment of pilasters altogether, we are decidedly of opinion that they are often useful and important accessories in a building. It would be difficult to enumerate every situation wherein it is expedient to use pilasters rather than insulated or engaged columns. In internal apartments, where the space is restricted, a column appears heavy and occupies too much room. The materials, moreover, which can be obtained, often restrict the architect to the use of pilasters, over which the projections of the entablature are not so great; indeed, as the author in the *Encyclopédie Methodique* ob-

serves, a pilaster may be considered as a column in bas-relief, and is thus, from the diminished quantity of labour and material in it, simpler and more economical in application. That in houses and palaces of the second class the decoration by pilasters is of great service may be amply shown by reference to the works of Bramante, San Gallo, Palladio, and the other great masters of Italy, no less than in this country to those of Jones, Wren, and Vanbrugh.

2677. In profiling the capitals of Tuscan and Doric pilasters there can of course arise no difficulty; they follow the profiles of those over the columns themselves. In the capitals, however, of the other orders, some difficulties occur: these are thus noticed by Chambers. "In the antique Ionic capital, the extraordinary projection of the ovolo makes it necessary either to bend it inwards considerably towards the extremities, that it may pass behind the volutes, or, instead of keeping the volutes flat in front, as they commonly are in the antique, to twist them outwards till they give room for the passage of the ovolo. Le Clerc" (*Traité d'Architecture*) "thinks the latter of these expedients the best, and that the artifice may not be too striking, the projection of the ovolo may be considerably diminished, as in the annexed design" (*fig. 923.*), "which, as the moulding can be seen in front only, will occasion no disagreeable effect."

2678. "The same difficulty subsists with regard to the passage of the ovolo behind the angular Ionic volutes. Le Clerc therefore advises to open or spread the volutes sufficiently to leave room for the ovolo to pass behind them, as in the design" (*fig. 924.*) "annexed; which may be easily done, if the projection of the ovolo is diminished. Inigo Jones has in the Banqueting House made the two sides of the volutes parallel to each other, according to Scamozzi's manner, and at the same time has continued the ovolo in a straight line under them, so that the volutes have an enormous projection; which, added to the other faults of these capitals, renders the whole composition unusually defective and exceedingly ugly."

Fig. 923.

Fig. 924.

2679. "What has been said with regard to the passage of the ovolo behind the volutes in the Ionic order is likewise to be remembered in the Composite; and in the Corinthian the lip or edge of the vase or basket may be bent a little inwards towards its extremities, by which means it will easily pass behind the volutes. The leaves in the Corinthian and Composite capitals must not project beyond the top of the shaft, as they do at San Carlo in the Corso at Rome, and at the Banqueting House, Whitehall; but the diameter of the capital must be exactly the same as that of the top of the shaft. And to make out the thickness of the small bottom leaves, their edges may be bent a trifle outwards, and the large angular leaves may be directed inwards in their approach towards them, as in the annexed design" (*fig. 925.*), "and as they are executed in the church of the Roman college at Rome. When the small leaves have a considerable thickness, though the diameter of the capital is exactly the same as that of the shaft, in each front of the Composite or Corinthian pilaster capital, there must be two small leaves with one entire and two half large ones. They must be either of olive, acanthus, parsley, or laurel, massed, divided, and wrought, in the same manner as those of the columns are, the only difference being that they will be somewhat broader."

Fig. 925.

2680. It is desirable to avoid the use of pilasters at inward angles penetrating each other, because of the irregularity such practice produces in the entablatures and capitals. One break is quite as much as should be ever tolerated, though in many of the churches in Rome they are multiplied with great profusion of mutilated capitals and entablatures; "than which," observes Chambers, "nothing can be more confused or disagreeable."

2681. Neither should columns be allowed to penetrate each other, as they do in the court of the Louvre, inasmuch as the same irregularity is induced by it as we have above noticed in the case of pilasters.

## SECT. XV.

### CARYATIDES AND PERSIANS.

2682. The origin of caryatides we have in the First Book (165, *et seq.*) so far as regards our own opinions, explained, and in that respect we shall not trouble the reader. Our object in this section is merely to offer some observations on the use of them in modern practice. The figures denominated Persians, Atlantes, and the like, are in the same category, and we shall not therefore stop to inquire into their respective merits; indeed, that has already been sufficiently done in the book above alluded to. The writer of the article in the *Encyclopédie Methodique* has, we think, thrown away a vast deal of elegant writing on the subject of caryatides; and using, as we have done, to some extent, that extraordinary work, we think it necessary to say that we cannot recommend anything belonging to that article to the notice of the reader, except what is contained in the latter part of it, and with that we do not altogether agree.

2683. The object, or apparent object, in the use of caryatides is for the purpose of support. There is no case in which this cannot be better accomplished by a solid support, such as a column, the use of the attic order, or some other equivalent means. But the variety in quest of which the eye is always in search, and the picturesque effect which may be induced by the employment of caryatides, leads often to their necessary employment. The plain truth is, that they are admissible only as objects necessary for an extreme degree of decoration, and otherwise employed are not to be tolerated. There can, as we imagine, be no doubt that the most successful application of these figures as supports was by Jean Gougeon in the Louvre; as was the most unfortunate in the use of them in a church in the New Road, which at the time of its erection was much lauded, but which we hope will never be imitated by any British architect.

2684. As to the use of what are called Persians or male figures, originally in Persian dresses, to designate, as Vitruvius tells us, the victory over their country by the Greeks, the observations above made equally apply, and in the present day their application will not bear a moment's suspense in consideration.

2685. We have been much amused with the gravity wherewith Sir William Chambers, not with his usual sound sense, treats the claims of the personages whose merits we are discussing: he says, "Male figures may be introduced with propriety in arsenals or galleries of armour, in guard-rooms and other military places, where they should represent the figures of captives, or else of martial virtues; such as strength, valour, wisdom, prudence, fortitude, and the like." He writes more like himself when he says, "There are few nobler thoughts in the remains of antiquity than Inigo Jones's court" (in the design for the great palace at Whitehall), "the effect of which, if properly executed, would have been surprising and great in the highest degree." (See *fig. 207.*)

2686. What is called a *terminus*, which is, in fact, nothing more than a portion of an inverted obelisk, we shall not observe upon further than to say that it is a form, as applied to architecture, held in abhorrence. For the purpose, when detached and isolated, of supporting busts in gardens, it may perhaps be occasionally tolerated: further we have nothing to say in its favour. Those who seek for additional instruction on what are called termini, may find some account of them, as the boundary posts of land among the Romans, in books relating to the antiquities of that people.

2687. We shall now proceed to submit some examples of caryatides for the use of those whose designs require their employment. *Fig. 926.* is from a model of Michael Angelo

Fig. 926

Fig. 927.

Fig. 928.

Fig. 929

Buonarrotti, and is extracted from the *Treatise on Civil Architecture*, by Sir William Chambers, as are the succeeding examples.

2688. Figs. 927. and 928. are also designs by Michael Angelo, which, though not designed for a building, are well adapted for the purpose under certain conditions.

2689. Fig. 929. is the design of Andrea Biffi, a sculptor of Milan, in the cathedral of which city it is one of the figures surrounding the choir. The statue possesses much grace, and was admirably suited to the edifice wherein it was employed.

2690. Fig. 930. comes from Holland, having been executed by Artus Quellinus in the judgment-hall of the Stadthouse at Amsterdam.

Fig. 930.

Fig. 931.

Fig. 932.

Fig. 933.

Fig. 934.

2691. Fig. 931. is by Michael Angelo, and is at the Villa Ludovisi at Rome.

2692. Fig. 932. is from the design by the last-named master for the monument of Pope Julius, whereof we have had occasion already to make mention in the First Book of this work. (335.)

2693. Fig. 933. is a representation of one of the celebrated caryatides by Jean Gougeon in the Swiss guard-room of the old Louvre at Paris, and does not deserve less admiration than it has received. The scale on which this and the preceding figures are given does not admit of so good a representation as we could wish.

2694. Fig. 934. is from the arch of the goldsmiths at Rome, being thereon in basso rilievo, but considered by Chambers as well as ourselves a suitable hint for carrying out the purpose of this section.

## SECT. XVI.

### BALUSTRADES AND BALUSTERS.

2695. A baluster is a species of column used as an ornamental railing in front of windows, or in arcades, or on the summit of a building, whose professed object is the protection of its inhabitants from accidents: analogously, too, it consists of a capital, shaft, and base.

2696. The baluster is not found in the works of the ancients, and we believe it owed its introduction in architecture to the restorers of the arts in Italy, in which country a vast variety of examples are to be found. They made their first appearance in the form of stunted columns, not unfrequently surmounted by a clumsily-shaped Ionic capital. The term is said to have had its rise (with what truth we cannot pronounce) from the Latin *balaustum*, or the Greek *βαλαντιον*, the flower of the wild pomegranate, to which in form the architectural baluster is said by some to bear a resemblance. The writer in the *Encyclopédie Methodique* has taken the opportunity, in the article "Balustre," of launching his anathema against the use of it, but we by no means agree with him; and instead of calling it, as he does, "*une invention mesquine*," we incline to think that it was almost the only invention of the modern architects that deserves our admiration. It is true that the form has been abused in every possible shape; but we are not, in art more than in morals, to arrive at the conclusion that anything is bad because it has been abused and misapplied. Such, then, being the case, we shall proceed in a serious vein to consider its proportions, founded on the best examples that have come to our hands. We must first premise with J. F. Blondel, that balusters and balustrades, which last are a series of the first, should in form and arrangement partake of the character of the edifice. They have even been in their species so subdivided as to be arranged under as many classifications as the orders themselves, a distinct sort having been assigned for employment with each order. We are not quite certain that such an arrangement is necessary, but are rather inclined to think it fanciful; though we are quite willing to allow that where the lighter orders are employed,

the balustrades to be used over them are susceptible of a more minute and lighter subdivision of their parts.

2697. The general rules to be observed in the use of the balustrade are, that its balusters be of an odd number, and that the distance between them should be equal to half their larger diameter, from which will result an equality between the open and solid spaces. Blondel disapproves of a half baluster on the flanks of a subdivision of a balustrade: in this we dissent from him, and would always recommend its adoption if possible. In respect of the detailed proportions of the balusters themselves, we are to recollect that the subdivisions are of the capital, the shaft or vase of the baluster, and its base. For proportioning these to one another, Chambers (and we think the proportions he uses not inelegant) divides the whole given height into thirteen equal parts, whereof the height of the baluster is eight, that of the base three, and of the cornice or rail two. If the baluster is required to be less, he divides the height into fourteen parts, giving eight to the baluster, four to the base, and two to the rail. He calls one of these parts a module for the measurement of the rest, and that measure we think convenient for adoption in this work. The module he divides into nine parts.

2698. Balusters intended for real use in a building, as those employed on steps or stairs, or before windows, or to enclose terraces, should not be less than three feet in height, nor more than three feet six inches; that is, sufficiently high to give security to the persons using them: but when merely used as ornamental appendages, as in crowning a building, they should bear some proportion to the parts of the building. Chambers says that their height never ought to exceed four fifths of the height of the entablature on which they are placed, nor should it ever be less than two thirds, without counting the zoccolo or plinth. the height of which must be sufficient to leave the whole balustrade exposed to view from the best point of sight for viewing the building. We can scarcely admit these rules to pass without noting the examples in Palladio's works, which give a much greater latitude for variety. When balusters fill in between the pedestals, as in the façade of the Palace Chiericato at Vicenza, the balustrade's height is of course regulated by that of the pedestal itself; but in the court of the Porti palace the crowning balustrade is not higher than the cornice of the entablature on which it stands. The same proportion is observed in the atrium of the Carità at Venice. In the Valmarana palace the height of the balustrade is equal to that of the entablature of the small order. It is true that in a few instances this master made the height of the balustrade equal to that of the whole entablature, and Inigo Jones has in some instances followed his example; but this was not the general practice either of the one or the other.

2699. We have already said that the baluster generally varies in form, so as to be appropriate to the order over which it is used. It is moreover to be observed that the baluster is susceptible of a pleasing variety of its form by making it square instead of circular on the plan, whereof examples are given in *figs.* 938, 939, and 940.; but when the situation requires an expression of solidity, almost all the circular examples we submit to the reader may be changed from a circular to a square form on the plan, and thus as required we may obtain the character suitable to their respective situations. These changes, from one to another form in details of this description, are in their adoption much more the index to the capacity and genius of the architect than the restless and capricious longing after variety recently exhibited in some of the latest works produced in the city of London, works which reflect no credit on the age in which we live. In *fig.* 935. is given a baluster

Fig. 935.

Fig. 936.

Fig. 937.

suitable to the Tuscan order; and using the module of nine parts above mentioned, the following is a table of its dimensions:—

Members.					Heights in Parts of a Module.	Projections in Parts of a Module from Centre of Baluster.
Rail, 2 modules.	Fillet	-	-	-	3	27½
	Corona	-	-	-	8½	24½
	Quarter round	-	-	-	4½	
	Fillet	-	-	-	1½	
Baluster, 8 modules.	Abacus	-	-	-	5½	11½
	Cyma reversa	-	-	-	4	
	Neck	-	-	-	5	5½
	Astragal	-	-	-	3½	
	Fillet	-	-	-		
	Centre of belly	-	-	-	27	13
	From same to astragal	-	-	-	9	
	Astragal	-	-	-		
	Fillet	-	-	-	2½	10½ fillet
	Inverted cyma	-	-	-	6½	
Pedestal, 3 modules.	Plinth	-	-	-	7½	13
	Inverted cavetto	-	-	-	5	
	Fillet	-	-	-	2	
	Astragal	-	-	-	5	
	Plinth	-	-	-	15	24

2700. In *fig. 936.* is given the form of a baluster suited to the Doric and Ionic orders, of which also the table of dimensions is subjoined : —

Members.					Heights in Parts of a Module.	Projections in Parts of a Module from Centre of Baluster.
Rail, 2 modules.	Fillet	-	-	-	2	27
	Cyma reversa	-	-	-	3½	
	Corona	-	-	-	7	22
	Quarter round	-	-	-	4	
Baluster, 8 modules.	Fillet	-	-	-	1½	
	Abacus	-	-	-	5½	11
	Echinus	-	-	-	3½	
	Fillet	-	-	-	1	
	Neck	-	-	-	5	5
	Astragal	-	-	-	3	
	Fillet	-	-	-		
	Centre of belly	-	-	-	27	12½
	From same to astragal	-	-	-	9	
	Astragal	-	-	-	2	
	Fillet	-	-	-	1	
	Inverted cavetto	-	-	-	6	10 (upper part)
	Fillet	-	-	-	2½	
Pedestal, 3 modules.	Plinth	-	-	-	7½	12½
	Fillet	-	-	-	1½	
	Inverted ogee	-	-	-	5	
	Fillet	-	-	-	1½	
	Astragal	-	-	-	4½	23½

2701. A suitable baluster for the Corinthian or Composite order is exhibited in *fig. 937.*, whereof the measures are as follow : —

Members.					Heights in Parts of a Module.	Projections in Parts of a Module from Centre of Baluster.
Rail, 2 modules.	Fillet	-	-	-	1 $\frac{2}{3}$	26 $\frac{1}{2}$
	Echinus	-	-	-	2 $\frac{2}{3}$	
	Fillet	-	-	-	1	
	Corona	-	-	-	6 $\frac{1}{2}$	21 $\frac{1}{2}$
	Cyma reversa	-	-	-	3 $\frac{2}{3}$	
	Astragal	-	-	-	2 $\frac{2}{3}$	
Baluster, 8 modules.	Fillet	-	-	-	2 $\frac{2}{3}$	
	Abacus	-	-	-	5	10 $\frac{1}{2}$
	Echinus	-	-	-	3	
	Fillet	-	-	-	2 $\frac{1}{3}$	
	Cavetto	-	-	-	2 $\frac{1}{3}$	
	Neck	-	-	-	5	4 $\frac{3}{4}$
	Astragal	-	-	-	2 $\frac{2}{3}$	
	Fillet	-	-	-	2 $\frac{2}{3}$	
	Centre of belly	-	-	-	27	12
	From same to astragal	-	-	-	9	
	Astragal	-	-	-	2 $\frac{2}{3}$	
	Fillet	-	-	-	2 $\frac{2}{3}$	
Pedestal, 3 modules.	Scotia	-	-	-	4 $\frac{1}{2}$	4 $\frac{3}{4}$ (at top)
	Fillet	-	-	-	1	
	Astragal	-	-	-	3 $\frac{2}{3}$	
	Plinth	-	-	-	6	12
	Fillet	-	-	-	2 $\frac{2}{3}$	
	Astragal	-	-	-	2 $\frac{2}{3}$	
	Inverted cyma recta	-	-	-	4 $\frac{1}{2}$	
	Fillet	-	-	-	1	
	Astragal	-	-	-	4	
	Plinth	-	-	-	15	23

2702. The Tuscan baluster (*fig. 938.*) is suitable for terraces and basements: its rail

Fig. 938.

Fig. 939.

Fig. 940.

Fig. 941.

Fig. 942.

Fig. 943.

and pedestal may be the same height as in the *fig. 935.* Its principal measures being as follow:—

Members					Heights in Parts of a Module.	Projections in Parts of a Module from Centre of Baluster.
Baluster 5 modules.	Abacus	-	-	-	3	6
	Cyma reversa	-	-	-	2	
	Neck	-	-	-	4	3
	Fillet	-	-	-	4	
	Rustic belly { at top	-	-	-	27	4 $\frac{1}{2}$
	{ at bottom	-	-	-	27	7 $\frac{1}{2}$
	Bottom of belly	-	-	-	2 $\frac{1}{2}$	
	Fillet	-	-	-	2 $\frac{1}{2}$	
	Inverted cavetto and fillet	-	-	-	3	3
	Plinth	-	-	-	3 $\frac{1}{2}$	7 $\frac{1}{2}$

Other forms of Tuscan balusters are given in *figs.* 939. and 940., but it is not necessary to give the detail of the parts, as the proportions are sufficiently preserved in the figures.

2703. The double-bellied baluster is used in situations where greater lightness is required from the smallness of the parts and the delicacy of the profiles. The proportions for the bases and rails need not vary from those already given. Perhaps they need not be quite so large.

2704. *Fig.* 941. is an example of a double-bellied baluster, suitable to the Doric order. Its parts are as follow : —

Members.					Heights in Parts of a Module.	Projections in Parts of a Module from Centre of Baluster.
Baluster, 8 modules.	Abacus	-	-	-	$4\frac{1}{2}$	8
	Echinus	-	-	-	$4\frac{1}{2}$	
	Fillet	-	-	-		
	Upper part	-	-	-	$24\frac{3}{4}$	{ 4 neck 8 belly
	Middle part	-	-	-	$4\frac{1}{2}$	6 centre
	Lower part	-	-	-	$24\frac{3}{4}$	{ 8 belly 4 neck
	Fillet	-	-	-		
	Inverted echinus	-	-	-	$4\frac{1}{2}$	
	Plinth	-	-	-	$4\frac{1}{2}$	8

2705. In *fig.* 942. we give an example of the double-bellied baluster for the Ionic order, and its measures are subjoined : —

Members.					Heights in Parts of a Module.	Projections in Parts of a Module from Centre of Baluster.
Baluster, 10 modules.	Abacus	-	-	-	$4\frac{1}{2}$	9
	Fillet and cyma reversa	-	-	-	$4\frac{1}{2}$	
	Upper part	-	-	-	$30\frac{1}{2}$	{ $4\frac{1}{2}$ neck 9 belly
	Middle part	-	-	-	9	$7\frac{1}{2}$ centre
	Lower part	-	-	-	$30\frac{1}{2}$	{ 9 belly $4\frac{1}{2}$ neck
	Inverted cyma and fillet	-	-	-	$4\frac{1}{2}$	
	Plinth	-	-	-	$4\frac{1}{2}$	9

2706. The last example we shall give of the double-bellied baluster (*fig.* 943.) is suitable to the Corinthian order. The measures are as follow : —

Members.					Heights in Parts of a Module.	Projections in Parts of a Module from Centre of Baluster.
Baluster, 12 modules.	Abacus	-	-	-	5	11
	Echinus and fillet	-	-	-	4	
	Neck	-	-	-	$5\frac{1}{2}$	$5\frac{1}{2}$
	Astragal and fillet	-	-	-	$3\frac{1}{2}$	
	Upper part	-	-	-	29	{ $5\frac{1}{2}$ at top 11 at belly
	Middle	-	-	-	6	
	Lower part	-	-	-	29	{ 11 at belly $5\frac{1}{2}$ at bottom
	Fillet and astragal	-	-	-	$3\frac{1}{2}$	
	Neck	-	-	-	$5\frac{1}{2}$	$5\frac{1}{2}$
	Fillet and inverted echinus	-	-	-	4	
	Plinth	-	-	-	5	11

2707. We do not deem it necessary to give any examples of the scroll and Guilloche balustrades, which were so much in vogue during the reigns of Louis XIV. and Louis XV., though the present taste seems almost to require it. As that taste has been mainly generated by house decorators, as they are called, and upholsters, these gentry will soon find out another means of amusing the public, by driving them out of fashion and finding all that is beautiful in some renovated and equal absurdities.

2708. We have already observed that the intervals between balusters should not be more than half the diameter of the baluster at its thickest part; to this we may here add, that they should not be less than one third of that diameter. The pedestals for supporting the rail ought neither to be too frequent nor too far apart; for in the first case they impart a heavy appearance to the work, and in the last the work will seem weak. Seven or nine balusters are good numbers for a group, besides the two half ones engaged in the pedestals. The disposition, however, and number of the pedestals depend on the places below of the piers, columns, or pilasters, for over these a pedestal must stand; and when, therefore, it happens that the intervals are greater than are required for the reception of nine balusters, the distance may contain two or three groups each, flanked with half balusters, and the width of the dies separating the groups may be from two thirds to three quarters the width of the principal pedestals. The rail and base should not be broken by projections, but run in unbroken lines between the pedestals.

2709. When the principal pedestals stand over columns or pilasters, their dies should not be made wider than the top of the shafts, and on no account narrower; indeed, it is better to flank them on each side when the ranges are long with half dies, and give a small projection to the central pedestal, and to let the base and rail follow the projection in their profiles. This practice will give real as well as apparent solidity to the balustrade.

2710. *Fig. 944.* shows the application of a balustrade to a portion of a staircase, and herein the same proportions are observed as on level ranges. Some masters have made the mouldings of the different members of the baluster, follow the *rake* or inclination of the steps; but the practice is vicious: they should preserve their horizontality, as exhibited in the figure, in which, at A and B, is also shown the method in which the horizontal are joined to the inclined mouldings of the base and rail. In the balustrades of stairs the spaces between the balusters are usually made narrower than they are on level beds; and Le Clerc recommends that the height of the plinth should be equal to that of the steps; but this is not absolutely required, though it must on no account be less.

2711. The bulbs or bellies of balusters and their mouldings may be carved and otherwise enriched: indeed, in highly decorated interiors, this seems requisite.

2712. The following observations as to the height of statues placed upon balustrades are from Sir William Chambers: — "When statues are placed upon a balustrade their height should not exceed one quarter of the column and entablature on which the balustrade stands. Their attitudes must be upright, or, if anything, bending a little forwards, but never inclined to either side. Their legs must be close to each other, and the draperies close to their bodies, for whenever they stand straddling with bodies tortured into a variety of bends, and draperies waving in the wind, as those placed on the colonnades of St. Peter's, they have a most disagreeable effect, especially at a distance, from whence they appear like lumps of unformed materials, ready to drop upon the heads of passengers. The three figures placed on the pediment of Lord Spencer's house, in the Green Park, which were executed by the late ingenious Mr. Spang, are well composed for the purpose."

2713. "The heights of vases placed upon balustrades should not exceed two thirds of the height given to statues," says the same author. We are not altogether averse to the application of either statues or vases in the predicated situations, but we think the greatest discretion is required in their employment. When it is necessary to attract the eye from an indispensably obtrusive roof, they are of great value in the composition; but we shall not further enter on this point of controversy, for such it is, inasmuch as many object to their use altogether, and have considerable reason on their side. We must, however, briefly state the ground of objection, and Chambers's answer as respects statues. There are, he says, some "who totally reject the practice of placing statues on the outsides of buildings, founding their doctrine, probably, upon a remark which I have somewhere met with in a French author, importing that neither men, nor even angels or demi-gods, could stand in all weathers upon the tops of houses or churches."

2714. "The observation is wise, no doubt," (we doubt the wisdom of it,) "yet, as a piece of marble or stone is not likely to be mistaken for a live demi-god, and as statues, when properly introduced, are by far the most graceful terminations of a composition, one of the most abundant sources of varied entertainment, and amongst the richest, most

Fig. 944.

durable, and elegant ornaments of a structure, it may be hoped they will still continue to be tolerated." We fear that if the only reasons for their toleration were those assigned by the author, their doom would soon be sealed.

## SECT. XVII.

## PEDIMENTS.

2715. A pediment, whose etymology is not quite clear, consists of a portion of the horizontal cornice of the building to which it is applied, meeting two entire continued raking cornices, and enclosing by the three boundaries a space which is usually plain, called the *tympañum*. It is not, however, necessary that the upper cornice should be rectilinear, inasmuch as the cornice is sometimes formed by the segment of a circle. The arrangement in question was the Roman *fastigium*, and is the French *fronton*. The Greeks called pediments *αετοι*, or eagles; why, this is not the place to inquire. The origin of the pediment, according to authors, seems to have arisen from the inclined sides of the primitive hut. This is a subject, however, which in the First Book (subsec. 5.) has been already considered, and we shall therefore in this section confine ourselves to its employment in the architecture of the day.

2716. Of the varied forms which, by masters even of acknowledged talent, have been given to the pediment, whether polygonal, with curves of contrary flexure, with mixed forms, broken in the horizontal part of the cornice or in the raking parts of it, or reversed in its office with two springing inclined sides from the centre, we propose to say no more than that they are such abuses of all rules of propriety, that we shall not further notice them than by observing that in regular architecture no practice is to be tolerated where the pediment is composed otherwise than of two raking unbroken and one horizontal unbroken cornice, or of the latter and one continued flexure of curved line. To these only, therefore, we now apply ourselves.

2717. Generally, except for windows and doors, the pediment ought not to be used, except for a termination of the whole composition; and though examples are to be found without number in which an opposite practice has obtained, the reader, on reflection, will be convinced of the impropriety of it, if there be the smallest foundation for its origin in the termination of the slant sides of the hut.

2718. The use of the pediment in the interior of a building is, perhaps, very questionable, though the greatest masters have used it. We think it altogether unnecessary; if the pyramidal form is desirable for any particular combination of lines, it may be obtained by a vast number of other means than that of the introduction of the pediment. Hence we are of opinion that the attempted apology for them in Sir William Chambers's work, is altogether weak and unworthy of him, and only to be explained by that master's own practice.

2719. Vitruvius ordains that neither the modillions nor dentils which are used in the horizontal cornice should be used in the sloping cornices of a pediment, inasmuch as they represent parts in a roof which could not appear in that position; and the remains generally of antiquity seem to bear him out in the assertion; but the Roman remains seem to bear a different testimony to the validity of the law, and to our own eyes the transgression affords pleasure, and we should recommend the student not to feel himself at all bound by it; for, as Chambers most truly observes, "The disparity of figure and enrichment between the horizontal and inclined cornices are such defects as cannot be compensated by any degree of propriety whatever, and therefore to me it appears best, in imitation of the greatest Roman and modern architects, always to make the two cornices of the same profile, thus committing a trifling impropriety to avoid a very considerable deformity."

2720. Different sized pediments in the same façade are to be avoided; but as respects their forms in ranges of windows and niches a pleasing variety is often obtained by making them alternately curved and rectilinear, as in the temple at Nismes and in the niches of the Pantheon at Rome.

2721. In the horizontal part of a cornice under a pediment the two upper mouldings are always omitted, and the intersection of the inclined with the horizontal lines, supposing the inclined members of the cornice to be of the same height as those which are horizontal, will not fall into the profile (fig. 945.) whereof AB and BC are the leading lines. To obviate this inconvenience, some architects have made a break in the cymatium and fillet, as shown

Fig. 945.

in the figure. But this is a bad practice, and to it we prefer either making the cyma and fillet higher, as the dotted line AD indicates, or altogether lowering the height of the cyma on the horizontal line. If the inclined cornice is joined on each side by horizontal ones, the best expedient is to give only such small projection to the cyma as that it may meet the inclined sides.

2722. The heights of pediments should be regulated by their lengths, independent of the consideration of climate. (See Book II. Chap. III. Sect. IV. 2027.) Thus, when the base of the pediment is short, the height of the pediment may be greater; and when long, it should be diminished; for in the former case the inclined cornice leaves but scanty space for the tympanum, and in the latter case the tympanum will appear overcharged. From one fifth to one quarter of the length appears to have been agreed on as the limits; but we subjoin, from a work by Stanislas L'Eveillé (*Considerations sur les Frontons*, 4to. Paris, 1824), the method which we consider the best for determining the height of a pediment, observing, by the way, that a strict adherence to the ordinary rules for finding the height may produce the absurdity of a pediment higher than the columns by which it is borne, a condition which would not at all accord with the view we have taken of the orders in Sect. II.

Fig. 946.

Chap. I. of this Book. In fig. 946. we have a synoptical view of pediments of various extents, and as the letters applied to the central pediment will apply to all the rest, we shall restrict our description to that. Suppose the points  $a$  and  $b$  to be the extremities of the fillet of the corona. Then, with a radius equal to  $ab$ , from the points  $a$  and  $b$ , describe the arcs  $ax$ ,  $bx$ , and from their intersection  $x$  with the same radius let the arc  $ayb$  be described. From  $y$ , as a centre, with a radius equal to the height of the horizontal part of the cornice, describe the portion of the circle  $fg$ , and from  $a$  and  $b$  draw thereto tangents intersecting in  $y$ . Then  $yb$  and  $ya$  will be the proper inclination of the fillet of the corona to which the other members of the inclined parts will necessarily be parallel.

2723. We conclude this section by the words of Chambers. "The face of the tympan is always placed on a line perpendicular with the face of the frieze; and when large, may be adorned with sculpture, representing the arms or cypher of the owner, trophies of various kinds, suited to the nature of the structure, or bas-reliefs, representing either allegorical or historical subjects; but when small it is much better left plain."

## SECT. XVIII.

### CORNICES.

2724. In many cases the façades of buildings are erected without any of the orders appearing in the design, other, perhaps, than those which are applied as the dressings of windows, niches, or doors. The palaces of Florence and Rome abound with such examples, in most of which the edifice is crowned with a cornice, which adds dignity to the building, producing a play of light and shadow about it of the utmost importance as regards its picturesque effect. The moderns have generally failed in this fine feature of a building, and it is only within the last few years, in this country, that a return to the practice of the old masters, a practice properly appreciated by Jones, Wren, Vanbrugh, and Burlington, has manifested itself. If a building be entirely denuded of pilasters and columns, and there are very few common instances that justify their introduction, it seems rational to

deduce the proportion of the height and profile of its cornice from the proportions that would be given to it if an order intervened.

2725. If we consider the height of the crowning cornice of a building in this way, and as the portion of an entablature whose height is, as in the case of an order, one fifth of that of the building, we should immediately obtain a good proportion by dividing the whole height into 25 parts and giving two of them to the height of the cornice. For the

entablature being one fifth of the whole height, and its general division being into 10 parts, four whereof are given to the cornice, we have for its height the  $\frac{4}{10}$  of  $\frac{1}{5} = \frac{4}{50} = \frac{2}{25}$ , or the twelfth and a half part of the total height of the building = 0.08.

Now there are circumstances, such as when the piers are large, and in other cases when the parts are not very full in their profiles, which may justify a departure from the strict application of this rule; but it will be seen that in the following ten well-known examples the practice has not much differed from the theory, nearly the greatest deviation being in the celebrated cornice of the Farnese palace, which is here placed (*fig. 947.*) as an extraordinary work of art in connection with the building it crowns. The examples alluded to are as follow, and we shall begin with those of earlier date, the diminution in height being almost a chronological table of their erection, with the exception of those by Palladio:—

Fig. 947.

In the Spannochi palace, at Siena, the cornice is  $\frac{81}{1000}$  of the whole height of building, or  $\frac{3}{37} = .081$ .

In the Piccolomini palace, at Siena, the cornice is  $\frac{74}{1000}$  of the whole height of building, or  $\frac{3}{26} = .074$ .

In the Pojana palace, built by Palladio, at Pojana, in the Vicentine territory, the cornice is  $\frac{71}{1000}$  of the whole height of building, or  $\frac{1}{14} = .071$ .

In the Strozzi palace, at Florence, the cornice is  $\frac{69}{1000}$  of the whole height of building, or  $\frac{2}{29} = .069$ .

In the Pandolfini palace, at Florence, by Raffaele, the cornice is  $\frac{69}{1000}$  of the whole height of building, or  $\frac{2}{29} = .069$ .

In the Villa Montecchio, by Palladio, the cornice is  $\frac{69}{1000}$  of the whole height of building, or  $\frac{2}{29} = .069$ .

In the Villa Caldogno, by Palladio, the cornice is  $\frac{69}{1000}$  of the whole height of building, or  $\frac{2}{29} = .069$ .

In another villa by Palladio, for the family of Caldogno, the cornice is  $\frac{66}{1000}$  of the whole height of building, or  $\frac{1}{15} = .066$ .

In the Farnese palace, at Rome, the cornice is  $\frac{59}{1000}$  of the whole height of building, or  $\frac{1}{17} = .059$ .

In the Gondi palace, at Florence, the cornice is  $\frac{57}{1000}$  of the whole height of building, or  $\frac{2}{35} = .057$ .

From these examples it appears that the mean height of the cornices under consideration is something more than one fifteenth of the height of the building, and experience shows that, except under particular circumstances, much more than that is too great, and much less too little, to satisfy an educated eye. The grace beyond the reach of art is, if we may use an Hibernicism, in the power of few, but the bounds have been passed with success, as is testified in the Farnese palace. It may be objected to the system that we have generally adopted in this work, that we are too much reducing the art to rules. But this is a practice of which the painter is not ashamed in the proportions of the human figure, and we must remind our reader and the student that all rules are more for the purpose of restraining excess than bounding the flights of genius.

2726. *Fig. 948.* is an entablature by Vignola, which possesses great beauty, and has been often imitated in various ways for crowning a building; this must be con-

Fig. 948.

sidered more in relation to a building than a mere cornice, and requires rustic quoins, if possible, at the angles when used. Chambers, speaking of this example, says, that "when it is used to finish a plain building, the whole height is found by dividing the height of the whole front into eleven parts, one of which must be given to the entablature, and the remaining ten to the rest of the front." We suspect that the smallness which is assigned by this author to its height has been induced by some error, and that a better rule would be induced by assigning to the cornice its proper height, according to the laws above hinted at, and proportioning the rest of the entablature from the cornice thus obtained.

Fig. 951.

Fig. 950.

Fig. 949.

2727. In *figs. 949, 950, and 951.* are given three examples of block cornices (the second being by Palladio), whose proportions the figures sufficiently show without here giving a detail of their parts. The height of either should not be less than one fifteenth of the height of the building.

Fig. 952.

Fig. 954.

Fig. 953.

2728. *Figs. 952, and 953.* are block cornices, which we have adopted from Chambers, the first being from a palace at Milan, and the other, by Raffaele, in a house in the Lungara at Rome. The height of these, says the author, and we agree with him, need not exceed one sixteenth part of the whole front, nor should either be less than one eighteenth. *Fig. 954.* is what is called an architrave cornice, which was frequently employed by the old masters. It seems well adapted to the entablatures of columns bearing arches, being rather in the nature of an impost; but it is useful, changing it to suit the order in cases where the height does not admit of the whole of the entablature being used over the order.

## SECT. XIX.

### PROFILES OF DOORS.

2729. One of our objects in this work has been to impress throughout on the minds of our readers that architecture does not depend on arbitrary laws; and though we may not have proved satisfactorily to the student that the precise laws have been exactly stated, we trust we have exhibited sufficient to show and convince him that there was a method and limit in the works of the ancients which in the best times prevented the artists from falling on either side into excess.

2730. In *fig. 955.* we give a door with its architrave, frieze, and cornice, without relation to mouldings, but merely considered in the masses. Its proportions correspond with those most usually adopted; that is, its height is twice its width, the entablature is one fourth of the height of the opening, and the architraves on each side, together, two sixths of the width. The opening, therefore, measuring it in terms of the width of the architrave, will be 6 parts wide and 12 high, and its area consequently 72 parts. Now

it will be found that the solid parts of this are exactly on their face two thirds of this area; for up to the top of the opening each architrave being equal to 12, the sum will be 24; and the entablature being 8 wide and 3 (one fourth of twelve) high,  $8 \times 3 = 24$ ; which added to 24 for the architraves gives 48 for the solids, and  $\frac{48}{72} = \frac{2}{3}$ , as above stated. The same analogy does not seem to hold in respect of doors and windows, of making the voids equal to the supports and weights, as in intercolumniations; nor indeed ought we to expect to find it, for the conditions are totally different, inasmuch as no door can exist except in a wall, whereas the office of columns is connected with the weight above only. We trust, therefore, we have shown enough to keep the reader's mind alive to some such law as above developed, without insisting very strongly on a minute attention to it in detail.

FIG. 955.

2731. We shall now, before submitting any examples of doorways to the reader, touch upon some important points that must be attended to; the first of which is, that all gates and doors, independent of all other considerations, must be of sufficient size for convenient passage through them. Hence internal doors must never be reduced under 2 feet 9 or 10 inches, and their height must not be under 6 feet 10 inches or 7 feet, so as to admit the tallest person to pass with his hat. These are minimum dimensions for ordinary houses in the principal floors; but for houses of a superior class, which are provided with what may be called state apartments, widths of 4, 5, and 6 feet, folding doors and the like, will not be too great for the openings, and the heights will of course be in proportion. The entrance doors of private houses ought not to be under 3 feet 6 inches, nor ordinarily more than 6 feet in width; but in public buildings, where crowds of people assemble, the minimum width should be 6 feet, and thence upwards to 10 or 12 feet. No gate should be less than 9 feet wide; and when loaded waggons or carts are to pass through it, 11 or 12 feet will not be too much. As a general observation we may mention that all doors should open inwards, for otherwise the person entering pulls the door in his face, which is an inconvenient mode of entering a room. Also when the width of a door is greater than 3 feet 8 inches it should be formed in two flaps, by which three advantages accrue: first, that the door will not occupy so much space for opening; second, that each door will be lighter; and, third, that the flaps will more nearly fold into the thickness of the wall. Chambers properly says, "That in settling the dimensions of apertures of doors regard must be had to the architecture with which the door is surrounded. If it be placed in the intercolumniation of an order, the height of the aperture should never exceed three quarters of the space between the pavement and the architrave of the order; otherwise there cannot be room for the ornaments of the door. Nor should it ever be much less than two thirds of that space, for then there will be room sufficient to introduce both an entablature and a pediment without crowding; whereas if it be less it will appear trifling, and the intercolumniation will not be sufficiently filled. The apertures of doors placed in arches are regulated by the impost, the top of the cornice being generally made to level with the top of the impost; and when doors are placed in the same line with windows, the top of the aperture should level with the tops of the apertures of the windows; or if that be not practicable without making the door much larger than is necessary, the aperture may be lower than those of the windows, and the tops of all the cornices made on the same level."

2732. To say that the principal door of a building should if possible be in the centre of the front would seem almost unnecessary; but it is not so, perhaps, to inculcate the necessity of its being so situated in connection with the internal arrangement of the building as to lead with facility to every part of it, being, as Scamozzi observes (*Parte Seconda*, lib. vi. c. 4.), like the mouth of an animal placed in the middle of the face, and of easy communication with the *inside*. In the internal distribution the doors should as much as possible be opposite one another on many accounts, not the least whereof is the facility thus given to ventilation; but such a disposition also gives the opportunity of a far better display of a series of rooms, which on occasions of fêtes imparts great magnificence to the apartments. In this climate it is well to avoid too great a number of doors, and they should never, if it can be avoided, be placed near chimneys, because of subjecting to draughts of air those who sit near the fire. Generally the doors in a room should be reduced to the smallest number that will suit the distribution, and the practice of making feigned or blank doors, though sometimes necessary, should if possible be excluded.

2733. The ornaments with which doors are decorated must of course depend on the building in which they are used; and as this is a matter in which common sense must direct the architect, it is hardly necessary to say that the ornaments applied to them in a theatre would ill suit a church.

2734. The composition and designing of gates and their piers must of necessity suit the occasion, as well as the folding gates attached to them, for the enclosure of the parks,

gardens, and other places they are to serve. There are few finer examples in the higher class of this species of design than the celebrated gates at Hampton Court.

2735. The evil days on which we have fallen in this country, in respect of the arts, precludes the hope of again seeing the doors of our buildings ornamented with bassi relievi and bronze ornaments, a practice common among the ancients no less than among the revivers of the arts; witness the doors of St. Peter's, and, above all, those monuments of the art, the doors of the baptistery at Florence by Lorenzo Ghiberti, wherein art rises by being made only subservient to the holy purpose to which it is the mere handmaid. In the mention of doors those of San Giovanni Laterano at Rome must not be omitted; they have the credit of having been the enclosures to the temple of Saturn in the ancient city.

2736. The manufacture of doors has been already sufficiently noticed in the Second Book; and it therefore only remains for us to subjoin a few examples, which, we think, among many others, deserve the attention of the student.

Fig. 957.

Fig. 956.

Fig. 958.

2737. Fig. 956. is an external doorway designed and executed by Vignola, at Caprarola, not a great distance north of Rome; it must speak for itself: if the reader be of our mind, he will see in it a beautiful handling of the subject; but we cannot further answer for our opinion, knowing as we do that some of the reviewers of these days may find out that it possesses no *aesthetic* beauties. There are cases where imitation has been permitted; and the sanction for our opinion is, that it has been imitated by one whom we and all others hold in reverence at Greenwich Hospital, though, as we think with Chambers, for the worse. "The aperture is in the form of an arch, and occupies somewhat more than two thirds of the whole height. It is adorned with two rusticated Doric pilasters and a regular entablature. The height of the pilasters is 16 modules, that of the entablature 4. The width of the aperture is 7 modules, its height 14, and the breadth of each pier is 3 modules." To the detail of Chambers we have to add that the void in this example, which has no analogy to that which as a general rule we gave in the commencement of the section, is about one third of the area of the whole design, the void being to such area as 7·57 to 20·88.

2738. Fig. 957. is a design by the last-mentioned master, in which the void is as nearly as possible equal to one third of the area, the supports another, and the weights the other third: in other terms, the aperture occupies two thirds of the whole height and one half of the whole breadth, being, in fact, a double square. Its entablature has an alliance with the Tuscan order, and the cornice is equal to one fifteenth of the whole height of the door. These two examples are especially external; those which follow are from their nature applicable in general form to either external or internal doorways.

2739. Fig. 958. is a doorway in the Cancellaria at Rome, and is from the design of Vignola. The width is one half the height, and the height of the entablature is equal to one third of the height of the aperture. The breadth of the architrave is one fifth of the aperture's width, and the pilasters below the consoles are half as broad as the architrave. It is heavy, as might have been expected from the proportion between the voids and the solids.

2740. Fig. 959. is a design by Michael Angelo Buonarroti, and its aperture may be twice its height,

Fig. 959.

Fig. 960.

the whole entablature a quarter of its height, and the architrave one sixth of the width of the aperture. The face of the pilasters or columns at the sides must be regulated by the lower fascia of the architrave, and their breadth is to be a semidiameter.

2741. *Fig. 960.* is by Vignola, and is in the Farnese palace at Rome. The opening is twice the width in height, and the entablature is three elevenths of the height of the aperture, one of the foregoing elevenths being given to the architrave. The whole of the ornament on the sides is, including architraves and pilasters, equal to two sevenths of the width of the aperture. The cornice is Composite, with modillions and dentils, and the frieze is enriched with a laurel band.

2742. *Fig. 961.*, another of the examples given by Chambers, is believed to be by Cigoli. The void is rather more in height than twice its width. The impost of the arch is equal to half a diameter, the columns are rather more than nine diameters high, and rusticated with five square cinctures. The entablature is not so much as one quarter of the height of the column, and its tablet is equal to the width of the aperture.

*Fig. 961.*

*Fig. 962.*

*Fig. 963.*

2743. *Fig. 962.* is by Inigo Jones, and the aperture may be twice as high as it is wide. The architrave may be a sixth or seventh of the width of the aperture, the top of it being level with the astragal of the columns, which are Corinthian, and ten diameters in height. They must be so far removed on each side from the architrave as to allow the full projection of their bases. The entablature may be from two ninths to one fifth of the column, and the pediment should be regulated by the rules given in Sect. XVII. (2722.).

2744. *Fig. 963.* is by Serlio. The aperture may be a double square, or a trifle less; the diameter of the columns a quarter of the width of the aperture, or a trifle less; their height 8 to  $8\frac{1}{2}$  diameters; the entablature about a quarter of the height of the columns, and the pediment should be drawn in conformity with the directions in Sect. XVII.

## SECT. XX.

### WINDOWS.

2745. Windows, of all the parts of a building, are those which require the greatest nicety in adjustment between the interior and exterior relations of them. The architect who merely looks to the effect they will produce in his façades has done less than half his work, and deserves no better name or rank than that of a mere builder. It seems almost useless to observe that the windows of a building should preserve the same character, that those in each story must be of the same height, and that the openings must be directly over one another. Blank windows are, if possible, to be avoided. they always indicate that the architect wanted skill to unite the internal wants of the building with its external decoration. Windows, moreover, should be as far removed as the interior will permit from the quoins of a building, because they not only apparently, but really, weaken the angles when placed too near them.

2746. Vitruvius, Palladio, Scamozzi, and Philibert de l'Orme, besides many other masters, have given different proportions to them as connected with the apartments to be lighted. That these should be different is indicated by the different places in which those masters have written. Nothing, indeed, seems so much to disallow general laws as the proportion of windows to an apartment; according to the climate, the temperature, the

length of the days, the general clearness of the sky, the wants and customs of commerce and of life generally. In hot climates the windows are always few in number and small in dimension. As we approach those regions where the sun has less power and the winter is longer, we observe always an increase in their size and number, so as to enable the inhabitants to take as much advantage as possible of the sun's light and rays. It seems, therefore, almost impossible to give general rules on this subject. We shall on this account endeavour, in the rules that this section contains, to confine ourselves to the sizes which seem suitable in this climate, as respects the proportion of light necessary for the comfort of an apartment.

2747. It is a matter of experience that the greatest quantity of light is obtained for an apartment when lighted by an horizontal aperture in the ceiling. Of this a very extraordinary verification is to be found in the Pantheon at Rome. This edifice, whose clear internal diameter is 142 feet 6 inches, not including the recesses behind the columns, is nearly 74 feet high to the springing of the dome, which is semicircular. The total clear number of cubic feet in it may therefore be taken in round numbers at 1,934,460 cubic feet. Those who have visited it well know that it is most sufficiently and pleasingly lighted, and this is effected by an aperture (the *eye*, as it is technically called,) in the crown of the dome, which aperture is only 27 feet in diameter. Now the area of a circle 27 feet in diameter being rather more than 572 feet, it follows that each superficial foot of the area lights the astonishing quantity of nearly 3380 cubic feet. Independent of all considerations of climate, this shows the amazing superiority of a light falling vertically, where it can be introduced. But in a majority of cases the apertures for light are introduced in vertical walls; and the consequence is, that a far greater area of them for the admission of light becomes necessary. In considering the question it must be premised that a large open space is supposed before the windows, and not the obstructed light which it is the lot of the inhabitants of closely-built streets to enjoy. Again, it is to be recollected that in the proportioning of windows it is the apartments on the principal floor that are to be considered, because their width in all the stories must be guided by them, the only variety admissible being in the height. In this country, where the gloom and even darkness of wet, cloudy, and foggy seasons so much prevails, it is better to err on the side of too much rather than too little light, and when it is superabundant to exclude it by means of shutters and blinds. We are not very friendly to the splaying of windows, because of the irregularity of the lines which follows the practice; but, it must be admitted, it often becomes necessary when the walls are thick, and in such cases a considerable splay on the inside increases the light in effect by a great diminution of shade. It is well, if possible, to have an odd number of windows in an apartment: nothing wherein contributes more to gloom than a pier in the centre.

2748. We do not think it necessary to advert to the rule of Palladio for the dimensions of windows given in the first book of his work, chap. 25.; because, were it true for the climate of northern Italy, it would not be so for that of Great Britain; neither are we at all satisfied with that which in his practice Sir William Chambers says he adopted, and which is as follows, in his own words:—"I have generally added the depth and height" we suppose width "of the rooms on the principal floor together, and taken one eighth part thereof for the width of the window; a rule to which there are few objections: admitting somewhat more light than Palladio's, it is, I apprehend, fitter for our climate than his rule would be." This rule is empirical, as indeed is that on which we place most dependence, and to which we shall presently introduce the reader, being ourselves inclined to the belief that in the lighting a room there is a direct relation between the area of the aperture admitting the light and the quantity of cube space in the room. Indeed the law which we are about to give is one founded on the cubic contents of the apartment; and if the results bore a regular ratio to that quantity, the discussion would be at an end, for we should then have only to ascertain the cubic contents, and, knowing how much an area of light one foot square would illuminate, the division of one by the other would supply the superficies of windows to be provided. Our own notion on this subject is, that 1 foot superficial of light in a vertical wall, supposing the building free from obstruction by high objects in the neighbourhood, will in a square room be sufficient for 100 cube feet if placed centrally in such room. It will, however, immediately occur to the reader, that this rule cannot in many cases satisfy the requirements of an apartment as respects the quantity of light necessary for its proper illumination. The subject is beset with numerous difficulties, which to overcome requires the greatest skill. In the case of an apartment, long as compared with its width, it is well known to every practical architect that windows of the same collective area at either of the narrow ends of such apartment will light it much more effectively than if the same area of light were admitted on either of the long sides, and most especially so, if it should happen that on such long side there were a pier instead of a window in the centre of such side. In illustration of what we mean, let us refer the reader to the ball room at Windsor Castle, an apartment 90 feet long, 34 feet wide, and 33 feet high. This room is lighted from the northern narrower side by a window nearly occupying the

width, and is supplied by an abundance of light. But had the same quantity of light been admitted from either of the long sides of the room, so many masses of shadow would have been introduced through the interposition of piers, that its effect would have differed most widely from the cheerful and airy aspect it now presents. We have taken this as an example that more presently occurs to us, but the reader from his observation will have no difficulty in supplying instances in corroboration of our impressions on this subject.

But we shall now proceed to give, in the author's own words, the rules of which we have spoken. That author is Robert Morris, and the work quoted is *Lectures on Architecture, consisting of Rules founded on Harmonick and Arithmetical Proportions in Building*. London, 8vo. 1734. "There are rules, likewise, for proportioning of light according to the magnitude of the room by which any room may be illuminated, more or less, according to the uses of them, and at the same time preserve an external regularity; which, as it is on an uncommon basis, I shall explain to you as well as I conveniently can. Let the magnitude of the room be given, and one of those proportions I have proposed to be made use of or any other; multiply the length and breadth of the room together, and that product multiply by the height, and the square root of that sum will be the area or superficial content in feet, &c. of the light required."

Fig. 964.

Fig. 965.

2749. "Example. Suppose a room (*fig. 964.*), whose magnitude is the arithmetical proportion of 5, 4, and 3, and is 20 feet long, 16 feet broad, and 12 feet high, the cube or product of its length, breadth, and height multiplied together is 3840, the square root of which sum is 62 feet. If the height of the story is 12 feet as before mentioned, divide that 62 feet into three windows; each window will contain 20 feet 8 inches of superficial light, and those will be found to be 3 feet 2 1/2 inches broad, and 6 feet 5 inches high, which are windows of two diameters."

2750. "Let us now suppose another room on the same range whose height is 12 feet, as the preceding example is, and its proportion (*fig. 965.*) shall be the cube. The product of that cube is 1728, and its root is 41 feet 4 inches, or thereabouts: divide that 41 feet 4 inches in two parts for two windows, and each will be 20 feet 8 inches of superficial light, and those will be two diameters in height, and the magnitude the same as the preceding room."

2751. "For example sake, I will only suppose one more room (*fig. 966*) upon the same range, and 12 feet in height, whose proportion shall be the arithmetical of 3, 2, and 1; that is, its height being 12 feet, the breadth will be 24 and length 36, the product of those numbers multiplied together will be 10368, and its root 101 feet 8 inches, or thereabouts: divide this room into five windows, each window will have 20 feet 4 inches superficial light, and the magnitude will be near or equal to the others, and if the proportion be 6, 4, and 3, and coved, the light is the same."

Fig. 966.

2752. "There is," says the author, rather perhaps simply, "but one objection to this rule to make it universal for all kinds of proportioned rooms on the same floor, and that is, the square root doth not always happen to be exact enough for to make them alike; but as the variation will be so small, it may be made use of; and if the area something exceeds the standard of the principal room, that room may be converted to a use which requires more than standard light, and the necessities of families sometimes require it. But, however, the rule will serve for the purpose near enough for any practice."

2753. "If you extend the rule to larger rooms, the same methods will be preserved even if the height be continued through two stories, if the upper windows be made square,

Fig. 967.

and to have two tire" (tiers) "of windows. Let us suppose the room (*fig. 967.*) with two tire of windows in height, to be 50 feet long, 40 feet wide, and 30 feet high, the arithmetical proportion of 5, 4, and 3, the product of those numbers multiplied together will be 60000, the square root of which sum is 245 superficial feet; divide that sum for the tire" (tiers) "of windows into three parts, or take one third of it, and that makes the attic or square windows 81 feet 8 inches superficial light; divide this into 5 windows, and they are 4 feet and half an inch square, and the five lower windows, consisting of 163 feet 4 inches superficial light, being what remains out of the 245 feet, the root, each of these windows is 4 feet and half an inch by 8 feet 1 inch, or two diameters, which 245 feet, the whole sum of the square root of the room, will sufficiently illuminate the same."

2754. The extreme piers should not, if possible, be less than half the width of the principal piers. This cannot always be obtained, but a much less width causes great irregularity, and that more especially when one of such end piers falls opposite a chimney breast, besides causing a great mass of shadow on the other side of the chimney, which has a tendency towards making the room dark and gloomy.

2755. Windows in the same story should be similar. There may be an occasional deviation for a great central window, but such deviation must be used with much caution. Another practice, most properly reprobated by Chambers, is that of intermitting the architrave and frieze of an order in the intervals between the columns to make room for windows and their enrichments, as on the flanks of the Mansion House in the city of London; a practice from which Sir Christopher Wren was, unfortunately, not exempt, as may be noticed in St. Paul's Cathedral.

2756. What are called Venetian windows are occasionally allowable, when so ranged and introduced as not to interfere with the composition, — a task often difficult to effect. They should not be much repeated, as in the front at Holkham, where they become actually disgusting. Though in the examples which follow there be two which are composed with semicircular-headed centres, we do not approve of the general use of examples designed on such principles, and would advise the student rather to study the composition of the Venetian window, when required, as in *fig. 968.*, which we do not present as one of beauty, but rather of propriety, where the want of light to the apartment renders a Venetian window expedient. The method of making sashes, shutters, and the other accessories of windows has been described in a previous section; we therefore proceed to offer a few of the most celebrated examples of windows. It is not necessary, after the investigation relative to the voids and solids of doors, to pursue the inquiry into the relative proportions of windows as respects that part of the subject. They are, in a measure, in regard to windows, subject to the same principles, and this, by trial, will be immediately apparent to the student; and we therefore shall not stop for such investigation.

Fig. 968.

2757. *Fig. 969.* is after the lower story of windows at St. Peter's at Rome, by Michael Angelo, and is rather less than the double square in height. The architrave is one seventh

Fig. 969.

Fig. 970.

of the aperture's width, being the same as that of the pilasters. The length of the consoles is one third of the width of the aperture, and the entablature one quarter of its height.

2758. *Fig. 970.* is from the Mattei palace at Rome, and is the design of Bartolomeo Ammanati. It possesses, though rather heavy, considerable beauty, and well deserves the attention of the student. Chambers, from whom we have selected many of our examples in this and others sections, says, "the parts made somewhat less would succeed better, as would also a pediment instead of the sloped covering at top:" but we entirely disagree with him, and are of opinion that what he proposes would ruin the design.

Fig. 971.

Fig. 972.

2759. *Figs. 971. and 972.* are the compositions of Bernardo Buontalenti. The apertures are a double square, or something less, the architraves a sixth or seventh of the apertures, and the pilasters may be about the same. The height of the entablature should not be more than a quarter that of the aperture, nor much less. The greatest length of the consoles should not exceed half the width of the aperture, nor should their least length be less than one third of it.

2760. *Fig. 973.* is from the old Louvre at Paris, and is by the celebrated Pierre Lescot,

abbot of Clugny in the reigns of Francis I. and Henry II. Its proportions are not much dissimilar from the two last examples.

Fig. 973.

Fig. 974.

Fig. 975.

2761. *Fig. 974.* is a window constantly used by Palladio. The opening is a double square, the breadth of the architrave equal to one sixth of the aperture, and the frieze and cornice together equal to double the height of the architrave. The breadth of the consoles equal to two thirds the width of the architrave. The breaks over the consoles in the bed mouldings of the cornice are perhaps not strictly correct, but are deviations from propriety which may be tolerated. The breaks in the upper vertical parts of the architrave would perhaps be better omitted. The practice generally should be avoided, except in cases where a greater length of cornice is wanted for the purpose of filling the bare walls to which the windows are applied.

2762. *Fig. 975.* is from the Banqueting House at Whitehall, by Inigo Jones. The aperture is a double square, the entablature one fourth of its height, and the architrave somewhat more than one sixth of its width.

2763. *Fig. 976.* is by Michael Angelo, and executed at the Farnese palace at Rome. It possesses all the wildness and fancy of the master, and though abounding with faults, is redeemed by its grandeur and originality.

2764. In *fig. 977.* is given the design by Ludovico da Cigoli of a window from the ground floor of the Renuccini palace in Florence. It can scarcely be properly estimated without its connection with the façade, to the character whereof it is in every respect suitable.

2765. *Fig. 978.* is a design of Palladio, nearly resembling that executed in the Barbarano palace at Vicenza. It has been imitated by Inigo Jones, and perhaps improved on by him, in the flanks at Greenwich Hospital.

Fig. 976.

Fig. 977.

Fig. 978.

Fig. 979.

2766. *Fig. 979.* is also by Palladio, and executed by him in the Porto palace at Vicenza.  
2767. *Fig. 980.* is the design of Raffaele Sanzio, and worthy of the reputation of that

great painter and architect. It is executed in the Pandolfini palace at Florence, on the principal floor. The height of the aperture is a very little more than twice its width, the architrave is one seventh the width of the aperture. The columns, which are Ionic, are

Fig. 980.

Fig. 981.

9 diameters high, and should be as much detached from the wall as possible. The distance of them from the architrave of the window is a quarter of a diameter, which is also the distance of the entablature from the top of the same architrave. The total height of the entablature is two ninths of that of the column, and the height of the pediment is one quarter of its base or somewhat less. The pedestals are one quarter of the height of the whole order.

2768. Fig. 981. is one of the windows of the Bracciano palace at Rome, by Bernini. The aperture is more than a double square, and the architrave about one sixth the width of the aperture. The entablature is only one fifth of the height of the columns, including their sub-plinths, and the pediment is less in height than one quarter of its extent.

Fig. 982.

Fig. 983.

2769. Fig. 982. is from the principal floor of the Palazzo Thiene at Vicenza. The aperture is two and two tenths of its width in height; the columns are nine diameters high, and one quarter engaged in the wall. The under sides of the Ionic capitals are level with the top of the aperture, having angular volutes with an astragal and fillet below the volute. The bases are Tuscan, and there are on each shaft five rustic dies of an equal breadth,

count of the distance between their respective situations ; but if it be great, it must have a very bad effect ; and therefore this must be well attended to and remedied, either by the above-mentioned method, or by entirely omitting statues at the top of the building, leaving the balustrade either free, or placing thereon vases, trophies, and other similar ornaments." Further on in the same work, the author says that "niches, being designed as repositories for statues, groups, vases, or other works of sculpture, must be contrived to set off the things they are to contain to the best advantage ; and therefore no ornaments should ever be introduced within them, as is sometimes injudiciously practised, the cove of the niche being either filled with a large scollop shell, or the whole inside with various kinds of projecting rustics, with moulded compartments, either raised or sunken, or composed of different coloured marbles, for all these serve to confuse the outline of the statue or group. It is even wrong to continue an impost within the niche, for that is of considerable disadvantage to the figures, which never appear so perfect as when backed and detached on a plain smooth surface. An excess of ornaments round the niche should likewise be avoided, and particularly masks, busts, boys, or any representation of the human figure, all which serve to divide the attention, and to divert it from the principal object."

2780. "The depth of the niche should always be sufficient to contain the whole statue, or whatever else it is to contain, it being very disagreeable to see statues, or any other weighty objects, with false bearings, and supported on consoles or other projections, as is sometimes done, and in the case of niches, the side views become exceedingly uncouth ; for in these a leg, an arm, a head, in short, those parts alone which project beyond the niche, appear and look like so many fragments, stuck irregularly into the wall." We trust we shall be excused for this and many other long quotations from Chambers, on account of the strong common sense with which they abound, though not always expressed in the most elegant language that might have been selected.

2781. We conclude the section with a few examples of niches, whose general proportions are sufficiently to be derived from the figures which represent them, and which, therefore, will not require our more minute description in this place, the diagrams themselves being the more useful mode of submitting the subject to the student.

Fig. 986.

Fig. 987.

Fig. 988.

Fig. 989.

2782. *Fig. 986.* is the simple niche, square and circular in the head and in the plan ; in the latter we have before, as a general rule, given the proportion of its height as twice and a half that of its width ; but the former, or the square-headed one, may be a double square, yet it never should exceed in height twice and a half its width.

2783. *Fig. 987.* is a common form of using the niche where the opening of windows with which it is accompanied requires a correspondent square recess for the niches, as also in interiors where the leading lines may require such an expedient.

2784. *Fig. 988.* shows the method of introducing niches in a rusticated basement, which is often requisite. The rustics are received on a flat ground, in which the niche is formed. The reader is not to understand that any of the figures are intended as models for imitation, but merely as modes on which, in using them, he may so work as to reduce them to his own views in the design whereon he is engaged.

2785. *Fig. 989.* is from the plate of Palladio's Egyptian Hall, and exhibits the violation of Chambers's excellent maxim of not allowing the impost to be continued round the springing of the niche. If niches are merely introduced for play of light and shadow without reference to their reception of statues, the practice of this abuse may be tolerated ; but certainly not in cases where statues are to be placed in them.

2786. *Fig. 990.* is the niche accompanied by entablature, pediment, architraves, consoles, and pedestals, as in the windows which have already

Fig. 990.

Fig. 991.

been given, and their proportions will serve as a guide in this; the only difference being, that a niche is inserted within the architrave of the opening.

2787. *Fig. 991.* is imitated from one of the niches of the Pantheon, for the details whereof the reader may refer to Desgodetz.

SECT. XXII.

CHIMNEY PIECES.

2788. It is not our intention to devote much of a space, necessarily restricted, to the consideration of designs for chimney pieces; not because we consider them unworthy of the serious attention of the student, nor because the ever-varying fashion of the day seems to create a desire for new forms, but because they come under the category of doors and windows (strange as it may seem) in respect of the relation of the void to the solid parts. We are not aware that any view of this nature has heretofore been involved in the consideration of them, but we are not the more on that account to be driven from our hypothesis. The examples of chimney pieces that have been given by Chambers, and, before him, by old Serlio, were but fashions of their respective days; and if it be possible to establish something like a canon on which they might be designed, we apprehend it would be useful to the student.

2789. A chimney piece is the ornamental decoration applied to the aperture of a chimney opening, and it seems but reasonable that in its general distribution it should be subject to those laws which regulate the ornaments of other openings. The forms and fancies into which this ornament of a room may be changed are infinite, and we therefore consider that if its appendages can be drawn into a consistent shape we shall be of service in the few

Fig. 992.

Fig. 993.

Fig. 994.

remarks subjoined. In *fig. 992.* the chimney opening to be decorated is 4·0 wide and 3 feet 6 inches high; its area is therefore equal to  $4 : 0 \times 3 : 6 = 14$  feet. The principle here recommended is to make the two supporting pieces equal to one half of that area, or seven feet, and the supported piece B equal to the other half. Now, as the height is 3 : 6, we shall have  $\frac{7}{3 \cdot 5} = 2$  for the width of the two piers, that is, each will be one foot wide. By the addition of these to the width of the opening, the dimension becomes six feet; and as B is to contain seven feet superficial, it follows that  $\frac{7}{6} = 1 \frac{1}{6}$  is the height of B that it may contain 7 feet.

2790. In *fig. 993.* we have shown the method of developing the principle; in it the supports, load, and void bear the same relation to each other as in the preceding figure. The entablature is divided into three equal parts for the architrave, frieze, and cornice, and trusses are placed on the pilasters by the sides of the architrave. The tablet is of course not absolutely required, and the trusses may be formed of leaves instead of being plain, as here shown.

2791. *Fig. 994.* is another mode of using the proportions given in *fig. 992.*, and upon it, as well as that last given, we have only to observe, they are not introduced as specimens of design, but solely with the view of illustrating a principle. The projection of chimney-pieces should not generally be greater than the whole width of the support, nor less than half.

2792. We wish we could give some rule for adjusting the size of a chimney opening to that of the room it is to warm. Morris, in his *Lectures on Architecture*, before quoted, imagined that he had found out one, and he speaks with confidence on the results which follow its use; but we confess we are not satisfied with them. We nevertheless should be wrong in omitting it, and therefore give his words for the consideration of the student. The first rule is as follows:—"To find the height of the opening of the chimney from any given magnitude of a room, add the length and height of the room together, and extract the square root of that sum, and half that root will be the height of the chimney." The second rule is as follows:—"To find the breadth of a chimney from any given magnitude

whose inner sides are on a line with the sides of the aperture, and their projection equal to that of the plinth of the base, that is, one fifth of a diameter of the column. The keystones incline forwards towards the top, and they are hatched, only the surface being left rough, as are likewise the dies on the columns, except at their angles, which are rubbed smooth. The entablature is Ionic, the architrave consisting of only two fasciæ, the frieze swelled, and the dentil band placed immediately on the frieze, without any intervening mouldings, a practice not very unusual with Palladio. The pedestals are rather more than one third the height of the columns. The dies and balusters stand on the platband of the basement, which was done to diminish the projection.

2770. *Fig. 983.* is a design by Inigo Jones, which has been much used in this country. It is rather higher than a double square. The width of the architrave is one fifth that of the aperture, and the rustics are a trifle less than the third of it. The entablature is two ninths of the height of the opening, and the height of the pedestal is  $\frac{27}{100}$ , or nearly so, of the height of the aperture and pedestal taken together.

Fig. 984.

Fig. 985.

2771. *Fig. 984.* is the design of a Venetian window by Colin Campbell, the compiler of the three first volumes of the *Vitruvius Britannicus*; and

2772. *Fig. 985.* is very similar to the Venetian windows in the west façade of the Horse Guards, executed by Kent. It is perhaps as favourable an example of this species of window as can be produced.

## SECT. XXI.

### NICHES, AND STATUES.

2773. A niche is a recess constructed in the thickness of a wall for the reception of different objects, such as statues more especially, but occasionally also for that of busts, vases, and tripods. Vitruvius makes no mention of niches, and but for an inscription published by Visconti in the *Monumenti Gabini* we should not have known that they were by the ancients called *zotheca*, or place for the reception of a figure. Our English word niche is evidently derived from the Italian *nicchio*, a shell.

2774. In the early Greek temple the niche is not found; at a later period, as in the monument of Philopappus, we find a circular and two quadrangular-headed niches occupied in the time of Stuart by statues; and it does not seem improbable that in the *Gymnasia*, *Agora*, *Stadia*, &c. of the nation mentioned, the use of the niche was not uncommon. But the different forms of the ancient tomb, and the early methods of sepulture, would soon suggest to the Greeks and Romans the use of the niche, especially in such tombs as were devoted to the use of a particular family. These sepulchres, whose subdivisions were called *columbaria*, had their walls ornamented with small niches for the reception of cinerary urns, or those containing the ashes of the dead. In these, a large-sized niche occupies the principal place in the apartment, and in this was deposited the urn or sarcophagus of the head of the family.

2775. The small temples (*adricula*) of the Romans are often found decorated with niches; and in the small building on the Lake of Albano, generally supposed to have been a *Nymphaeum*, we find each side of the interior dressed with six niches, whose height sufficiently indicates that they were provided for the reception of statues. In the temple of Diana, usually called the *maison carrée*, at Nîmes, which, however, is usually considered to

have been a building sacred to the Nymphs, the interior has two sides decorated with six Corinthian columns, and in the wall between each intercolumniation is a niche of the sort called tabernacles by the moderns. Each is placed on a pedestal, and is finished on the sides by pilasters alternately surmounted by segmental and triangular pediments. We do not, however, consider it necessary to enumerate the various Roman works wherein the niche finds a place, and shall therefore do no more than refer the student to the Pantheon, the temple of Peace, the arch of Janus, at Rome, and to its exuberant employment at Palmyra, Baalbek, and Spalatro. The buildings cited will furnish him with examples of all sorts and characters.

2776. The dresses of niches seem to bear an analogy to those of windows and doors in their form and decoration; the niche, indeed, may be considered as an opening in a wall, and indeed there are, in the arch of Claudius Drusus, now the Porta Maggiore, at Rome, openings used as niches, in which an object placed may be seen from either side of the wall. It therefore appears not improper to dress the niche with the ornaments which custom has sanctioned for doors and windows. The author of the article "Niche" in the *Encyclopedie Methodique*, has divided niches into three classes. The first are such as are square on the plan, and either square or circular-headed. These are the simplest, and are without dressings of any sort. Second, such as are square on their plans, and with square heads, but ornamented with dressings, or crowned with a simple platband supported by two consoles. In the third class are included all niches whose plan and heads are semicircular, either ornamented with festoons, or with dressings, or with columns and entablature. These, says the author, are to be introduced into buildings according to their several characters, from simple to highly enriched, as requisite.

2777. Some architectural authors have laid down positive rules for the proportions of niches. According to others the proportion is found in a niche twice and a half its width in height; and indeed this produces a proportion not inelegant. But in considering the classes separately, they have divided the width of the niches invariably into twelve parts. To a niche of the first class they give twenty-eight of such parts; to one of the second class, thirty; and to one of the third class, thirty-one parts. This reduction, however, of the proportions of a niche seems to us to partake of empiricism; and we would rather always trust to an educated eye than to rules which seem to have no basis on fitness and propriety. It is, however, to be recollected that all rules of art can be considered only as *mean terms*, serving more as approximations than positive laws for the guidance of the artist in the different combinations he imagines.

2778. The use of tiers of niches over each other is condemned by J. F. Blondel, unless separated by a line of entablature between them, which may seem to indicate the existence of a floor; otherwise, he observes, one figure seems to stand on the head of another. This, however, is an abuse of reasoning; not that it is to be understood that we think the practice very allowable. The recommendation of this master in respect of the relation between niches and the statues that are to occupy them is worthy of attention. He opposes, and we think with great propriety, the placing a statue without a plinth in the niche. The plinth is, indeed, necessary to the good effect of every statue; and to pretend that the imitation in marble could or ever was intended to be mistaken for the object it imitates, would be to leave behind all those matters of convention in art for which the spectator is well prepared. In architectural decoration, no less than in the abstract imitation of the objects of sculpture, no one is desirous of believing them natural and living, but only as models of imitation.

2779. The following observations are from Chambers, relative to the size of the statues used in niches. "The size of the statue depends upon the dimensions of the niche; it should neither be so large as to seem rammed into it, as at Santa Maria Maggiore, in Rome, nor so small as to seem lost in it, as in the Pantheon, where the statues do not occupy above three quarters of the height of the niche, and only one half of its width. Palladio, in arched niches, makes the chin of his statues on a level with the top of the impost (springing), so that the whole head is in the coved part. In the nave of St. Peter's, at Rome, the same proportion has been observed, and it has a very good effect. The distance between the outline of the statue and the sides of the niche should never be less than one third of a head, nor more than one half, whether the niche be square or arched; and when it is square, the distance from the top of the head to the soffit of the niche should not exceed the distance left on the sides. The statues are generally raised on a plinth, the height of which may be from one third to one half of a head; and sometimes, where the niches are very large in proportion to the architecture they accompany, as is the case when an order comprehends but one story, the statues may be raised on small pedestals, by which means they may be made lower than usual, and yet fill the niche sufficiently, it being to be feared lest statues of a proper size to fill such niches should make the columns and entablature appear trifling. The same expedient must also be made use of whenever the statues in the niches, according to their common proportions, come considerably larger than those placed at the top of the building. A trifling disparity will not be easily perceived, on ac-

of a room, add the length, breadth, and height of the room together, and extract the square root of that sum, and half that root will be the height of the chimney." The third rule he gives is, "To find the depth of a chimney from any given magnitude, including the breadth and height of the same, add the breadth and height of the chimney together, take one fourth of that sum, and it is the depth of the chimney." His fourth and last rule is, "To find the side of a square or funnel proportioned to clear the smoke from any given depth of the chimney, take three fourths of the given depth, and that sum is the side of the square of the funnel. Observe, only, that in cube rooms the height is equal to the breadth, and the foregoing rules are universal." The rules given by Chambers are extremely vague and general. He says that "in the smallest apartments the width of the aperture is never made less than from three feet to three feet six inches; in rooms from twenty to twenty-four feet square, or of equal superficial dimensions, it may be four feet wide; in those of twenty-five to thirty, from four to four and a half; and in such as exceed these dimensions, the aperture may be extended to five or five feet six inches; but should the room be extremely large, as is frequently the case of halls, galleries, and salons, and one chimney of these dimensions neither afford sufficient heat to warm the room nor sufficient space round it for the company, it will be much more convenient, and far handsomer, to have two chimney pieces of a moderate size than a single one exceedingly large, all the parts of which would appear clumsy and disproportioned to the other decorations of the room." It is well so to place the chimney as that persons on entering a room may at once see it. In this climate a cheerfulness is imparted by the sight of a fire; but it is not to be so placed as to be opposite a door, neither ought it, if possible to be avoided, to be so placed as to have a door on either side of it. There are, however, circumstances under which even the last-named category cannot be avoided, but it is always well if it can. The fact is, that the further the door can, generally speaking, be removed from a chimney, the better; and the architect must, if the plan admit it (and he ought so to distribute his parts), avoid all cross draughts of air in a room. Angular chimneys are only admissible in small rooms where space and other considerations permit no other means of introducing a chimney. We can hardly think it necessary to say, with Chambers, that "whenever two chimneys are introduced in the same room they must be regularly placed, either directly facing each other, if in different walls, or at equal distances from the centre of the wall in which they both are placed. He observes, however, with a proper caution to the student, that "the Italians frequently put their chimneys in the front walls, between the windows, for the benefit of looking out while sitting by the fire; but this must be avoided, for by so doing that side of the room becomes crowded with ornaments, and the other sides are left too bare; the front walls are much weakened by the funnels, and the chimney shafts at the top of the building, which must necessarily be carried higher than the ridges of the roofs, have, from their great length, a very disagreeable effect, and are very liable to be blown down." All these objections, however, may be easily answered, and the funnels collected, or shafts, as they then become, be, with skill, made even ornamental to a building. It is in cases like these that the power of the architect above the artisan is manifest.

2793. Where the walls of a building are sufficiently thick, their funnels rise within the thickness of the walls, but in walls of a mean thickness this cannot be accomplished, for under such circumstances the walls and chimney pieces will necessarily project into the rooms, and if the break be great, the effect is unpleasant; but this may always be obviated by making arched recesses on each side, which, in commoner rooms, may be occupied by presses or closets, thus enabling the architect to carry the cornice unbroken round the room, a point which should never be forgotten, inasmuch as by the cornice or entablature of the apartment being carried round it without a break, which gives the ceiling an unbroken and regular form, a regularity is preserved infinitely more satisfactory to the eye than the disagreeable appearance of a broken, and, we may say, disjointed cornice.

2794. Of the materials employed in the construction of chimney pieces, nothing more is requisite than to say that the costliness of the material must follow the wealth of the founder of the building. Marble, however, is the material usually employed, and the various sorts known are not unfrequently intermixed, so as to produce a pleasing effect. When the aid of the sculptor is called in, much latitude is allowed in the proportions; but on this head we hope we may, without prejudice, deliver our opinion, that the effect has never amounted to anything like what might have been expected from his extraneous aid; and the solution is easy: his object is not to produce a work in harmony with the apartment, but rather to exhibit his own powers.

2795. In the external appearance of chimney shafts, so as to group them with the building to which they belong, no architect can be put in competition with Sir John Vanbrugh. Those of Blenheim, Castle Howard, and other of his buildings, exceed all praise, and deserve the closest investigation of the student. They become in his works, as they always should do, parts of the building, inseparably connected with it, and their removal would detract from the majesty of the structure with which they are connected. On this point we are certain that the best advice that can be given to the student is a constant

contemplation of the works of Vanbrugh. In these days there seems to be a return to good feeling in this respect; and we hope it will, for the credit of the English school, be followed up.

## SECT. XXIII.

## STAIRCASES.

2796. A staircase is an enclosure formed by walls or partitions, or both, for the reception of an ascent of stairs, with such landings as may be necessary. Of the construction of stairs we have treated in previous sections; this will be confined to general observations on them and their enclosures.

2797. Scarcely any subdivision of a building is of more importance, as respects the character of the architect and the comfort and pleasant occupancy of it by his employer, than its principal and subordinate staircases. There is, moreover, no part, perhaps, in which more room is left for architectural and picturesque display. In our own country there are some extraordinary examples of great beauty produced in staircases on comparatively small scales; whence the student may learn that without great space he may produce very imposing effects. One of these may be still seen, though in a very neglected state, as are most of the buildings attached to the collegiate church of Westminster, at one of the prebendal houses there built by our great master Jones. It is a specimen of his consummate skill as an artist, and well worth the attention of the student, if he can obtain admittance to view it; but if he cannot, we may refer him to some plates executed from drawings made by us many years since, and published in the first and best edition of *Illustrations of the Public Buildings of London* (Lond. 1828). The extreme space occupied by the staircase in question does not exceed 24 by 23 feet; and within these small dimensions he contrived a staircase fit for a palace. So highly did the late Sir John Soane think of this bijou that he had a series of drawings made to illustrate its parts, and exhibited them in his lectures at the Royal Academy.

2798. It is almost unnecessary to impress upon the student that an excess rather than a deficiency of light is requisite in a staircase, and that it should be easily accessible from all parts of the building. Those laws upon which the ease of persons ascending and descending depend will form the subject of two subsections shortly following (2804. and 2814.), to which we particularly recommend the reader's attention. They are of the utmost importance, and we record with surprise that they have not been attended to by architects generally of late years. We have crept up staircases in houses of consequence, which deserved little more than the name of ladders, and we are sorry to say that this defect is found even in the works of Chambers himself; but never in those of Jones and Wren. We shall with these remarks proceed to further observations on the subject, which has already been partially touched upon in 2176, *et seq.*

2799. We know little of the staircases of the Greeks and Romans, and it is remarkable that Vitruvius makes no mention of a staircase, as an important part of an edifice; indeed his silence seems to lead to the conclusion that the staircases of antiquity were not constructed with the luxury and magnificence to be seen in more recent buildings. The best preserved ancient staircases are those constructed in the thickness of the walls of the pronaos of temples for ascending to the roofs. Of this sort remains are found in several peripteral temples. That of the temple of Concord at Agrigentum is still entire, and consists of forty-one steps. According to Pausanias, similar staircases existed in the temple of the Olympian Jupiter at Elis. They were generally winding and spiral, like the inside of a shell, and hence are called *scale a lumaca* by the Italians, and by the French *escaliers en limaçon*. Sometimes, as in the Pantheon at Rome, instead of being circular on the plan, they are triangular; so were they in the temple of Peace, and in the baths of Dioclesian.

2800. Very few vestiges of staircases are to be seen in the ruins of Pompeii; from which it may be inferred that what there were must have been of wood, and, moreover, that few of the houses were more than one story in height. Where they exist, as in the building at the above place called the country house, and some others, they are narrow and inconvenient, with steps sometimes a foot in height. Occasionally, too, we find private staircases mentioned, as in the description of Pliny's Tusculan villa, where one was placed by the side of the dining room, and appropriated to the use of the slaves who served the repast.

2801. The author of the article "Escalier" in the *Encyc. Method.* observes that the magnificence of the staircase was but tardily developed in modern architecture, and that it owed much of its luxury to the perfection to which a knowledge of stereotomy brought the science of masonry. The manners too and the customs of domestic life for a length of time rendered unnecessary more than a staircase of very ordinary description. Thus in the earliest palaces the staircases seem to have been constructed for the use of the inha-

bitants only, possessing in fact no more beauty than we now give to a back staircase. They are for the most part dark, narrow, and inconvenient. Even in Italy, which in the splendour of its buildings preceded and surpassed all the other nations of Europe, the staircase was, till a late period, extremely simple in the largest and grandest palaces. Such are the staircases of the Vatican, Bernini's celebrated one being comparatively of a late date. The old staircases of the Tuilleries and of the Louvre, though on a considerable scale, are, from their simplicity, construction, and situation, little in unison with the richness of the rest of these palaces. And this was the consequence of having the state apartments on the ground floor. When they were removed to a higher place, the staircase which conducted to them necessarily led to a correspondence of design in it.

2802. It will be observed that our observations in this section are confined to internal staircases. Large flights of steps, such as those at the *Trinità de' Monti* and *Araceli* at Rome, do not come within our notice, being unrestricted in their extent, and scarcely subject to the general laws of architectural composition. In these it should however be remembered that they must never rise in a continued series of steps from the bottom to the summit, but must be provided with landings for resting places, as is usually the case in the half and quarter spaces of internal stairs. An extremely fine example of an external flight of stairs may be cited in those descending from the terrace to the orangery at Versailles. For simplicity, grandeur, design, and beauty of construction, we scarcely know anything in Europe more admirable than this staircase and the orangery to which it leads.

2803. The selection of the place in which the staircase of a dwelling is to be seated, requires great judgment, and is always a difficult task in the formation of a plan. Palladio, the great master of the moderns, thus delivers the rules for observance in planning them, that they may not be an obstruction to the rest of the building. He says, "A particular place must be marked out, that no part of the building should receive any prejudice by them. There are three openings necessary to a staircase. The first is the doorway that leads to it, which the more it is in sight the better it is; and I highly approve of its being in such a place that before one comes to it the best part of the house may be seen, for although the house be small, yet by such arrangement it will appear larger: the door, however, must be obvious, and easy to be found. The second opening is that of the windows through which the stairs are lighted; they should be in the middle, and large enough to light the stairs in every part. The third opening is the landing place by which one enters into the rooms above; it ought to be fair and well ornamented, and to lead into the largest places first."

2804. "Staircases," continues our author, "will be perfect, if they are spacious, light, and easy to ascend; as if, indeed, they seemed to invite people to mount. They will be clear, if the light is bright and equally diffused; and they will be sufficiently ample, if they do not appear scanty and narrow in proportion to the size and quality of the building. Nevertheless, they ought never to be narrower than 4 feet" (4 feet 6 inches English\*), "so that two persons meeting on the stairs may conveniently pass each other. They will be convenient with respect to the whole building, if the arches under them can be used for domestic purposes; and commodious for the persons going up and down, if the stairs are not too steep nor the steps too high. Therefore, they must be twice as long as broad. The steps ought not to exceed 6 inches in height; and if they be lower they must be so to long and continued stairs, for they will be so much the easier, because one needs not lift the foot so high; but they must never be lower than 4 inches." (These are Vicentine inches.) "The breadth of the steps ought not to be less than a foot, nor more than a foot and a half. The ancients used to make the steps of an odd number, that thus beginning to ascend with the right foot, they might end with the same foot, which they took to be a good omen, and a greater mark of respect so to enter into the temple. It will be sufficient to put eleven or thirteen steps at most to a flight before coming to a half-pace, thus to help weak people and of short breath, as well that they may there have the opportunity of resting as to allow of any person falling from above being there caught." We do not propose to give examples of other than the most usual forms of staircases and stairs; their variety is almost infinite, and could not even in their leading features be compassed in a work like this. The varieties, indeed, would not be usefully given, inasmuch as the forms are necessarily dependent on the varied circumstances of each plan, calling upon the architect almost on every occasion to invent *pro re natâ*.

2805. Stairs are of two sorts, straight and winding. Before proceeding with his design, the architect must always take care, whether in the straight or winding staircase, that the person ascending has what is called *headway*, which is a clear distance measured vertically from any step, quarter, half-pace, or landing, to the underside of the ceiling, step, or other part immediately over it, so as to allow the tallest person to clear it with his hat on; and this is the minimum height of headway that can be admitted. To return to the straight and winding staircase, it is to be observed, that the first may be divided into two *flights*, or be

\* The Vicentine foot is about 13.6 inches English.

Fig. 995.

Fig. 996.

made quite square, so as to turn on the four sides round a close or open newel, as in *fig. 995*. in which the former is the case, light being obtained by windows in the walls which enclose the newel ; or, as in *fig. 996*. : in which case, the newel is open, and the light may be received either from a vertical light above, or from side windows in the walls. Palladio says these two sorts of stairs were invented by Sig. Lewis Cornaro, a gentleman of much genius, who erected for himself a magnificent palace at Padua.

2806. Of winding or spiral stairs, some are circular on the plan, either open or with a solid newel ; others elliptical, also with open or solid newels. Those with the open newel are preferable, because of their allowing the staircase to be lighted additionally, if requisite, by the light obtainable from above ; besides which, persons passing up and down may see each other. Palladio thus directs the setting out of spiral staircases. "Those," he says, "which have a newel in the middle are made in this manner. The diameter being divided into three parts, two are given for the steps, and the third is for the newel ; or, otherwise, the diameter may be divided into seven parts, three of which are for the newel and four for the steps. "Thus," he says, "was made the staircase of the column of Trajan at Rome ; and if the stairs are made circular," (that is, the treads segments of circles on the plan,) "they will be handsomer and longer" (of course) "than if made straight."

2807. "But as it may happen that the space will not give room for these measures, the diameter may be reduced and divided according to the plates." The essence of these plans, omitting the step whose plan is segmental, we here subjoin.

2808. *Fig. 997*. is a plan and section of a staircase with a solid newel, in which the whole diameter is divided into thirteen parts, and of these four are given to the newel, and the remainder divided equally between the steps.

Fig. 997.

Fig. 998.

2809. Fig. 998. is the plan and section of a spiral staircase with an open newel, wherein the diameter is divided into four parts, two being given to the newel, and the remainder equally divided between the steps.

2810. Fig. 999. is the plan and section of an elliptical staircase with an open newel. The conjugate diameter is divided into four parts, whereof two are given to the conjugate diameter of the newel, and the remainder one on each side to the steps.

2811. In fig. 1000. the same staircase is given, but with a solid newel, and of course requiring many openings on the sides to light it.

2812. It is not the difficulty of multiplying the examples of staircases which prevents our proceeding on this head, but the space into which our work is to be condensed. Enough of example has been given, by using portions of the examples, to meet every case, the decoration being dependent on the design of the architect, and the distribution on his good sense in the application of what we have submitted to him.

2813. There is, however, one important point in the construction of a staircase to which we must now advert, and that is easiness of ascent. Blondel, in his *Cours d'Architecture*, was, we believe, the first architect who settled the proper relation between the height and width of steps, and his theory, for the truth whereof, though it bears much appearance of it, we do not pledge ourselves, is as follows.

2814. Let  $x$  = the space over which a person walks with ease upon a level plane, and  $z$  = the height which the same person could with equal ease ascend vertically. Then if  $h$  be the height of the step, and  $w$  its width, the relation between  $h$  and  $w$  must be such that when  $w = x$ ,  $h = 0$ , and when  $h = z$ ,  $w = 0$ . These conditions are fulfilled by equations of the form  $h = \frac{1}{2}(x - w)$  and  $w = x - 2h$ . Blondel assumes 24 (French) inches for the value of  $x$ , and 12 for that of  $z$ . We are not sufficiently, from experiment, convinced that these are the proper values; but, following him, if those values be substituted in the equation  $h = \frac{1}{2}(24 - w)$ , and  $w = 24 - 2h$ : if the height of a step be 5 inches, its width should be  $24 - 10 = 14$  inches, and it must be confessed that experience seems to confirm the theory, for it must be observed, and every person who has built a staircase will know the fact, that the merely

Fig. 999.

Fig. 1000.

reducing the height of the risers without giving a correspondent width of tread the step is inconvenient and unpleasant.

## SECT. XXIV.

### CEILINGS.

2815. Economy has worked so great a change in our dwellings, that their ceilings are, of late years, little more than miserable naked surfaces of plaster. This section, therefore, will possess little interest in the eye of speculating builders of the wretched houses erected about the suburbs of the metropolis, and let to unsuspecting tenants at rents usually about three times their actual value. To the student it is more important, inasmuch as a well-designed ceiling is one of the most pleasing features of a room.

2816. There is, perhaps, no type in architecture more strictly useful in the internal distribution of apartments than that derived from timber-framing; and if the reader has understood our section on floors, he will immediately see that the natural compartments which are formed in the carpentry of a floor are such as suggest panels and ornaments of great variety. Even a single-framed floor with its strutting or wind-pieces between the joists, gives us the hint for a ceiling of coffers capable of producing the happiest effect in the most insignificant room. If the type of timber-framing be applied to the dome or hemispherical ceiling, the interties between the main ribs, diminishing as they approach the summit, form the skeletons of the coffers that impart beauty to the Pantheon of Agrippa. We allude thus to the type to inculcate the principle on which ornamented ceilings are designed, being satisfied that a reference to such type will insure propriety, and bring us back to that

fitness which, in the early part of this Book, we have considered one of the main ingredients of beauty. If the panels of a ceiling be formed with reference to this principle, namely, how they might or could be securely framed in the timbering, the design will be fit for the purpose, and its effect will satisfy the spectator, however unable to account for the pleasure he receives. Whether the architrave be with plain square panels between it and the wall, as in the temples of the Egyptians, or as at a later period decorated with coffers, for instance in the Greek and Roman temple, the principle seems to be the same, and verifies the theory. The writer of the article "Plafond" in the *Encyc. Meth.* has not entered into the subject at much length, nor with the ability displayed in many other parts of that work; but he especially directs that where a ceiling is to be decorated on the plane surface with painting, the compartments should have reference to the construction. With these preliminary observations, we shall now proceed to the different forms in use. Ceilings are either flat, coved, that is, rising from the walls with a curve, or vaulted. They are sometimes, however, of contours in which one, more, or all of these forms find employment. When a coved ceiling is used, the height of the cove is rarely less than one fifth, and not more than one third the height of the room. This will be mainly dependent on the real height of the room, for if that be low in proportion to its width, the cove must be kept down; when otherwise, it is advantageous to throw height into the cove, which will make the excess of the height less apparent. If, however, the architect is unrestricted, and the proportions of the room are under his control, the height of the cove should be one quarter of the whole height. In the ceilings of rooms whose figure is that of a parallelogram, the centre part is usually formed into a large flat panel, which is commonly decorated with a flower in the middle. When the cove is used, the division into panels of the ceiling will not bear to be so numerous nor so heavy as when the ceiling appears to rest on the walls at once, but the same sorts of figures may be employed as we shall presently give for other ceilings. If the apartment is to be highly finished, the cove itself may be

Fig. 1001.

Fig. 1002.

Fig. 1003.

Fig. 1004.

Fig. 1005.

Fig. 1006.

decorated with enriched panels, as in the *figs.* 1001, 1002, 1003, 1004, 1005, 1006. In all ceilings it is desirable to raise the centre panel higher than the rest, and the main divisions representing the timbers in flat ceilings should, if possible, fall in the centre of the piers between the windows.

2817. *Fig.* 1007. shows the ceiling of a square room in two ways as given on each side of the dotted line, or it may be considered as representing the ends of a ceiling to a room whose form is that of a parallelogram. The same observation applies to *figs.* 1008. and 1009. The soffits of the beams should in all cases approach the width they would be,

Fig. 1007.

Fig. 1008.

Fig. 1009.

considered as the soffits of architraves of the columns of the order to which the cornice belongs, and they may be decorated with guilloches, as in *fig. 1010.*, or with frets. (See the word "Fret" in Glossary.)

Fig. 1010.

2818. In the two following figures (1011. and 1012.) are given four examples of rooms which are parallelograms on the plan, and above each is a section of the compartments.

Fig. 1011

Fig. 1012.

2819. As to the proportion of the cornice, it ought in rooms to be perhaps rather less than in halls, salons, and the exterior parts of a building; and if the entablature be taken at a fifth instead of one fourth of the height, and a proportional part of that fifth be taken for the cornice, it cannot be too heavy. Perhaps where columns are introduced it will be better to keep to the usual proportions. Chambers, if followed, would make the proportions still lighter than we have set them down. He says that if the rooms are adorned with an entire order, the entablature should not be more than a sixth of the height nor be less than a seventh in flat-ceiled rooms, and one sixth or one seventh in such as are coved; and that when there are neither columns nor pilasters in the decoration, but an entablature alone, its height should not be above one seventh or eighth of those heights. He further says that in rooms finished with a simple cornice it should not exceed one fifteenth nor be less than one twentieth, and that if the whole entablature be used its height should not be more than one eighth of the upright of the room. In the ceilings of staircases the cornices must be set out on the same principles; indeed in these, and in halls and other large rooms, the whole of the entablature is generally used. In vaulted ceilings and domes the panels are usually decorated with panels similar to those in *figs. 1001, 1002, 1003, 1004, 1005, 1006.*, but in their application to domes they of course diminish as they rise towards the eye of the dome. (See 2837.)

## SECT. XXV.

### PROPORTIONS OF ROOMS.

2820. The use to which rooms are appropriated, and their actual dimensions, are the principal points for consideration in adjusting the proportions of apartments. Abstractedly considered, all figures, from a square to the sesquialteral proportion, may be used for the plan. Many great masters have carried the proportion to a double square on the plan; but except the room be subdivided by a break the height is not easily proportioned to it. This objection does not however apply to long galleries which are not restricted in length,

on which Chambers remarks, "that in this case the extraordinary length renders it impossible for the eye to take in the whole extent at once, and therefore the comparison between the height and length can never be made."

2821. The figure of a room, too, necessarily regulates its height. If a room, for example, be coved, it should be higher than one whose ceiling is entirely flat. When the plan is square and the ceiling flat the height should not be less than four fifths of the side nor more than five sixths; but when it leaves the square and becomes parallelogramic, the height may be equal to the width. Coved rooms, however, when square, should be as high as they are broad; and when parallelograms, their height may be equal to their width, increased from one fifth to one third of the difference between the length and width.

2822. The height of galleries should be at least one and one third of their width, and at the most perhaps one and three fifths. "It is not, however," says Chambers, "always possible to observe these proportions. In dwelling-houses, the height of all the rooms on the same floor is generally the same, though their extent be different; which renders it extremely difficult in large buildings, where there are a great number of different-sized rooms, to proportion all of them well. The usual method, in buildings where beauty and magnificence are preferred to economy, is to raise the halls, salons, and galleries higher than the other rooms, by making them occupy two stories; to make the drawing-rooms or other largest rooms with flat ceilings; to cove the middle-sized ones one third, a quarter, or a fifth of their height, according as it is more or less excessive; and in the smallest apartments, where even the highest coves are not sufficient to render the proportion tolerable, it is usual to contrive mezzanines above them, which afford servants' lodging-rooms, baths, *powdering-rooms*," (now no longer wanted!) "wardrobes, and the like; so much the more convenient as they are near the state apartments, and of private access. The Earl of Leicester's house at Holkham is a masterpiece in this respect, as well as in many others: the distribution of the plan, in particular, deserves much commendation, and does great credit to the memory of Mr. Kent, it being exceedingly well contrived, both for state and convenience."

2823. In this country, the coldness of the climate, with the economy of those who build superadded, have been obstacles to developing the proper proportions of our apartments; and the consequence is, that in England we rarely see magnificence attained in them. We can point out very few rooms whose height is as great as it should be. In Italy, the rules given by Palladio and other masters, judging from their works, seem to be sevenfold in respect of lengths and breadths of rooms, namely, — 1. circular; 2. square; 3. the length equal to the diagonal of the square; 4. length equal to one third more than the square; 5. to the square and a half; 6. to the square and two thirds; or, 7. two squares full. As to the height of chambers, Palladio says they are made either arched or with a plain ceiling: if the latter, the height from the pavement or floor to the joists above ought to be equal to their breadth; and the chambers of the second story must be a sixth part less than them in height. The arched rooms, being those commonly adopted in the principal story, no less on account of their beauty than for the security afforded against fire, if square, are in height to be a third more than their breadth; but when the length exceeds the breadth, the height proportioned to the length and breadth together may be readily found by joining the two lines of the length and breadth into one line, which being bisected, one half will give exactly the height of the arch. Thus, let the room be 12 feet long and 6 feet wide,  $\frac{12+6}{2} = 9$  feet the height of the room. Another of Palladio's methods of proportioning the height to the length and breadth is, by making the length, height, and breadth in sesquialteral proportion, that is, by finding a number which has the same ratio to the breadth as the length has to it. This is found by multiplying the length and breadth together, and taking the square root of the product for the height. Thus, supposing the length 9 and the breadth 4, the height of the arch will be  $\sqrt{9 \times 4} = 6$ , the height required; the number 6 being contained as many times in 9 as 4 is in 6.

2824. The same author gives still another method, as follows: — Let the height be assumed as found by the first rule ( $= 9$ ), and the length and breadth, as before, 12 and 6. Multiply the length by the breadth, and divide the product by the height assumed; then  $\frac{12 \times 6}{9} = 8$  for the height, which is more than the second rule gives, and less than the first.

## CHAP. II.

## COMBINATION OF PARTS.

## SECT. I.

## GENERAL PRINCIPLES OF COMPOSITION.

2825. THE end of architecture, without whose aid no other art can exist, is not merely to please the eye, but so to provide against the changes of the seasons as to be serviceable to man. Pleasure to the eye may, however, result from the useful, well combined with the beautiful modifications whereof it is susceptible. It is in combining thus that the genius of the architect is exhibited. The art of decorating a well-proportioned edifice is a very secondary and comparatively easy part of his work, though requiring, of course, the early cultivation of his taste and an intimate acquaintance with the parts, whereof this may be taught and that acquired; but the distribution and arrangement of the several portions on the plan, upon which every accessory is dependent, requires great knowledge and considerable experience. And in this is involved not only the general convenience and effect of the building, but what is of much consequence to the proprietor, the cost of the work. None but those practically conversant with the planning of a building would believe the saving that may be produced by proper distribution. In the case of many external breaks, for instance, much addition arises in the length of walls enclosing the edifice, without generally increasing the convenience of the interior, but always when the elevation comes to be adapted to the plan, with the certainty of breaking up the masses, and destroying the simplicity of the effect. This is mentioned merely as an instance of simplicity of plan always producing simplicity of section and elevation. The luxury and richness of decoration and the general appearance of a façade is the main source of the pleasure derivable from the exercise of the art, by persons unacquainted with it; and it is curious that these are the only matters with which the reviewer-critics of the day trust themselves, well knowing how quickly their ignorance would be discovered the moment they should pass the threshold, and discourse on the economy and distribution of a building. It is, indeed, singular in these days of art-reviewing, that for the last twenty years not a single paper of any *value* has appeared in any of the periodicals, in which the writer has ventured on that part of the subject. The fact is, that the number is very limited of those who can comprehend the plan of a building, or who, on walking over it, can so arrange in their minds the distribution of the several portions as to have the smallest notion whether it has been skilfully composed. The spectator, like the reviewer, looks at the façade, perhaps connects it in an angular view with one of the flanks, says it is heavy and mean, or grand and magnificent, according to his temperament and education, always excusing himself by admitting he does not understand architecture, but "he knows what pleases him." Now we doubt whether such persons in reality do know what pleases them, and we are certain they would be more suited for judges if they had "reason for the faith" that is in them.

2826. All ornament in architecture is non-essential, inasmuch as the pleasure received by the eye is not its end. To public and private utility, the welfare and comforts of individuals, which are the ends of the art, every other point must be sacrificed; and it is only when these have been accomplished that we are to think of decoration. We well remember the time, in our younger days, when the façade of the building to be designed was with us the important object of consideration. We have lived to know better; and the first time we seriously began, now many years since, to fall away from the error, arose from the anecdote told of a certain nobleman, who, having boasted to a friend of the beauty of the façade of his house, which within was exceedingly ill contrived, was told that he thought the peer would do well to take the house opposite, that he might be thus always able to look at it. Those who make the internal parts of an edifice subservient to the project of a façade, and adjust their plan and section to the elevation, must be considered as making the end of less importance than the ornament of the building. Those who work in this mode produce little variety in their designs, which, numerous though they be, consist of but few different combinations, whilst those that result from the natural order of making the façade subservient to the internal parts which the plan and section impose, are susceptible of infinite variety and decoration.

2827. It is not, however, to be supposed that we are, in what has been said, sanctioning the student's neglect of careful composition and adjustment of the façades. Upon the adaptation of the different fronts of the building to sort with the internal convenience,

the greatest care should be bestowed. It is from these his reputation is likely to flow, because they are the parts most susceptible of comprehension by the public. The architect will, upon every succeeding day's experience, find that the two objects are not incompatible; but if such a case, which is possible, arise, he had far better sacrifice the façade, considering first the comforts of those who are to inhabit the house, and then the gratification of those who are only to look at it.

2828. Durand has well observed that compositions conducted on the above principles must please. "Has not nature," says that author, "attached pleasure to the satisfaction of our wants, and are our most lively pleasures other than the satisfaction of our most pressing wants? These wants are better satisfied in the interior distribution of a building than in the exterior." Who leaves the Pantheon without more satisfaction than he expected from the view of the portico, fine though it be? Again, faulty as are both St. Peter's and St. Paul's, will any one who understands the subject aver that he has received more pleasure from their respective façades than from their noble interiors? The pleasurable sensations produced by both are entirely dependent on their interior distribution. But when we find that in the former of these buildings there is no mockery of a dome, the interior and exterior being as far dependent on each other as the circumstances of construction would permit, whilst the dome of the latter is worse than a mockery, the interior and exterior domes having nothing in common with each other, the last being no more than a timber leaded apurtenance to the fabric, Wren, with all his greatness, for great he was, shrinks into nothingness by the side of Michael Angelo, although the external form of the dome of London be more elegant than that of the Vatican. This is a strong but not a forced illustration of our opinions, the good sense whereof must be left for appreciation to our readers, who, we doubt not, on a little reflection, will concur with us.

2829. In ninety-nine cases out of a hundred the student will find that a good distribution of his plan leads him, with anything like ordinary tact, to the composition of good sections and good elevations, far better, indeed, than he could arrive at by pursuing an opposite course. In domestic Gothic architecture, this is notorious, for in that a regular distribution of the openings would often produce the tamest and least picturesque effect. The Gothic architects placed windows internally where only they would be serviceable, letting them take their chance in the exterior. It is not to be understood, because such would be rather *outré*, that this method will exactly suit the principles of composition in Italian architecture; but it is well known to practical men that a required opening in a particular place, instead of being a blemish, may be converted on many occasions into a beauty. Indeed, it is incontrovertibly true that distribution and disposition are the first objects that should engage the architect's attention, even of him whose great aim is to strike the attention by ornament, which can never please unless its source can be traced to the most convenient and economical distribution of the leading parts. Theorists may be laughed at, but it does not move us, nor diminish our regret to see many architects without any other theory than that whereon, in an inverted position, their own wild fancies are grafted. If what we have stated be true, and from the nature of things we cannot imagine a controversy can arise upon our observations, the talent of the architect is to be estimated, as Durand properly observes, according to his solution of the two following problems:—

First. For a given sum, as in private buildings, to erect the most convenient and suitable house for his employer.

Second. The requisites in a building being given, as in public buildings, to erect it at the smallest possible expense.

2830. An investigation of all the modes of accomplishing these desiderata can only be fully effected in a work of much larger extent than this; but we have, in the practical parts of our volume, so prepared the reader, that he will not generally be at a loss in respect of the construction of a building, whatever its nature or destination.

## SECT. II.

### DRAWINGS NECESSARY IN COMPOSITION.

2831. In the preceding parts of the work, we have described at as great a length as could be necessary the different parts that enter into the composition of a building, such as the orders, windows, doors, balustrades, and the like, which may be compared to the notes of the scale used in musical composition. These were placed in the foremost rank of our arrangement, otherwise we must have been, as it were, without words for our discourse or notes for the symphony we would produce. We have, moreover, under the section on drawing, given such general hints for what the musician might technically call scoring them, as ought to leave him in no difficulty as to what now follows; and we have arrived at the period when he cannot be supposed to want further instructions in these respects.

2832. For the thorough comprehension of a projected edifice, at least three drawings are necessary, the *plan*, the *section*, and the *elevation*. The first is an horizontal section of it, the second the vertical section, which shows the building as if it were cut in half, and that half nearest the spectator, removed from its plan, so as to permit the inner parts to become visible, and the third is the geometrical appearance of the front represented as if viewed from an infinite distance, in which no convergence of the lines would be seen.

2833. In making a design, it is always better to put the general idea together on a single sheet of paper, and consequently, in most cases, on a small scale. This, in afterwards making the drawings, is, as may be necessary, increased in size. The three parts being drawn under one another, as shown in *fig. 1013.*, wherein the middle diagram is the plan, the lower one the section, and the upper one the elevation. By thus beginning on a single sheet, in which the whole is before the eye, the corresponding lines are more readily transferred from one part to another. Having drawn through the middle of the paper the vertical *AA*, cut at right angles by the horizontal line *BB*, draw the required centres or axes of the walls *CC* and *DD*, and supposing the building is to be square, with the same opening of the compasses set out the axes of the return walls *EE* and *FF*. Having determined the thickness of the walls, one half may be set out on each side the axes, as in *ee, ff, cc, and dd*, and then the lines showing the thicknesses of the walls may be drawn. The width of openings in the walls may be next set out, half on each side the axes *BB* and *AA*, first drawn towards *bb* and *aa*, and the lines drawn to their places. Having thus proceeded, we shall discover that not only has the plan been drawn, but at the same time a considerable portion of the section and elevation. To distinguish the voids from the solids, the latter should be coloured or hatched, and then the next step will be as follows:— Parallel to the principal axis *BB*, draw the ground lines *GG* and *GG*. From these lines the heights of the building, its cornice and openings, may be set up in the section and elevation; and afterwards, the height of the roof and projection of the cornice having been determined, they may be set out and drawn. In the section, as in the plan, it is usual either to colour or hatch the solid parts, as we have done in the figure.

2834. Simple as the above process may be, it contains the whole elementary part of the mechanical process necessary for making a design. It might have been conducted on a more complicated mass, but had we done so, it would not have been so well understood, and we therefore deprecate any observations on the simpleness of our process by those who have been brought to know these things by practice and experience. We do not, however, feel we should discharge our duty before closing this section, without a censure on the attempt to convert drawings of *geometrical* elevations and sections into *picturesque* representations, because such practice is not only injurious to the art, but is dishonest, and has a tendency to mislead the architect's employer; and we are sorry to say that it is not unfrequently done with such a view. We denounce it, and without hesitation aver that the casting of shadows on a design is not admissible for the purpose of showing the relative depths of projecting parts; and when so admitted, the medium should be confined to Indian ink or sepia, and thrown in merely in masses, the apertures being just slightly filled in with the same colour.

Fig. 1013.

## SECT. III.

## CAISSONS IN CYLINDRICAL AND HEMISPHERICAL VAULTING.

2835. Previous to further proceeding, it will be expedient to touch on the method of setting out the *caissons* or sunken panels in cylindrical vaults and domes, a process required almost in every building of importance, and imparting great beauty to the effect of the interior when properly introduced: it is, indeed, one of the elements in composing them, and must therefore be well understood before the student can succeed in developing his ideas.

2836. In setting out the ribs of cylindrical vaulting, the vertical ones are supposed as falling on supports below the springing; but if such supports fall too wide apart, the caissons themselves will be too wide, and the space must be divided into a greater number; in which case, if practicable, an odd number is to be preferred, taking care that the caissons are not too much reduced in width. This, however, is only for the purpose of ascertaining roughly how many caissons may be used in the circuit of the vault; and it is to be remembered that they must be of an odd number, because a tier of caissons should always extend

Fig. 1014.

Fig. 1015.

along the crown of the vault. Fig. 1014. is an example of a cylindrical vault wherein the number of caissons is five. A is one half of its transverse section, and B a small portion of the longitudinal section. The width of the ribs between the caissons is one third of them; hence, if the number of caissons, as in the example, be five, the arch must be divided into twenty-one parts, one of which parts will be the width of a rib, and three will be given to the width of a caisson. As we have just observed, a caisson is always placed in the centre; we shall therefore have the half-arch =  $1\frac{1}{2} + 1 + 3 + 1 + 3 + 1 = 10\frac{1}{2}$  and  $10\frac{1}{2} \times 2 = 21$ . The vertical lengths of the sides of the caissons thus found will regulate the horizontal lengths of their sides, inasmuch as they should be made square. If the caissons in the vault be seven in number, as in fig. 1015., the soffit or periphery must be then divided into twenty-nine parts; if their number be nine, into thirty-seven parts; and so on increasing by eight each step in the progression. The caissons may be single or double sunk, or more, according to the richness required; their centres may be moreover decorated with *fleurons*, and their margins moulded with open enrichments. Where the apartment is very highly ornamented, the ribs themselves are sunk on their face, and decorated with frets, guiloches, and the like, as mentioned for ceilings in Chap. I. Sect. XXIV. Durand, in his *Cours d'Architecture*, regulates the width of the caissons entirely by the interaxes of the columns of the building; but this practice is inconvenient, because the space may in reality be so great as to make the caissons extremely heavy, which is, in fact, the case in the examples he gives.

2837. In the case of dome or hemispherical vaulting, the first point for consideration is the number of caissons in each horizontal tier of them; and the student must recollect that allowing, as before, one third of the width of a caisson as the width of a rib, the number of parts into which the horizontal periphery (whereof *e'e'* on the plan A is one quarter, and its projected representation at *ee* on the section B) is to be divided (fig. 1016.) must be multiples of 4, otherwise caissons will not fall centrally on the two axes of the plan. Thus,

A dome having	16 caissons in one horizontal tier must be divided into	64 parts.
—	20 ditto	80 ditto.
—	24 ditto	96 ditto.
—	28 ditto	112 ditto.
—	32 ditto	128 ditto.

and so on increasing by 16 for each term in the progression. In the figure the number of caissons is sixteen. The semi-plan is divided into thirty-two parts, three whereof are given to each caisson, and one and a half to each half-caisson on the horizontal axis of the plan. From

the divisions thus obtained lines are carried up to the section  $ab, ab, cd, cd$ . As the projected representations of the great circles of a sphere are ellipses, if from  $b, b, d, d$  we construct a series of semi-ellipses whose transverse diameters are equal to the semi-diameter of the sphere, and their conjugate axes determined from the points of intersection  $b, b, d, d$ , we shall have the vertical sides of the caissons. The next part of the process is to ascertain the ratio of diminution in the heights of the tiers of caissons as they rise towards the vertex, so that they may continue square in ascending. Upon a vertical line  $CC'$ , whose length is equal to the developed length of the line of dome  $ef$ , or in other words, whose length is equal to one quarter of the length of a great circle of the sphere, to the right and left of  $C$  set out at  $g$  and  $g$  the half width of the caisson obtained from the plan, and make  $hg, hg$  equal to one third of the caisson for the width of the ribs on each side. Draw lines to the vertex of the development from  $hh$  and  $gg$ . A diagonal  $hi$  being then drawn, the horizontal line  $ik$  will determine the lower edge of the next caisson upwards. Proceed in this way for the next from  $l$  and so on. The heights of the caissons thus obtained, being transferred to the section on the quadrant  $ef$ , will give the proportionate diminution thereon of the caissons as they rise. They are discontinued, and the dome is left plain, when they become so small as to lose their effect from below, and indeed they could not beyond a certain limit be executed.

Fig. 1016.

## SECT. IV.

## HORIZONTAL AND VERTICAL COMBINATIONS OF BUILDINGS.

2838. The different elements of a building are ranged by the side of or above each other, and in designing an edifice both these combinations must be kept in mind, though in the study of the subject, in order to lighten the labour, they may be separately considered. The two species of disposition are horizontal, as in plans, and vertical, as in sections and elevations.

2839. As respects horizontal disposition of the elements of a fabric, beginning with columns, their distance in the same edifice should be equal, but that distance may be varied as circumstances require. In buildings of small importance, the number is reduced as much as possible, on the score of economy, by increasing the distance between them; but in public buildings they should be introduced in greater number, as contributing to the greater solidity of the edifice by affording a larger number of points of support. They ought not, however, to be at all introduced except for the formation of porticoes, galleries, and the like subdivisions. The least distance at which they can be properly placed from a wall is that which they are apart from one another. This distance, indeed, suits well enough when the columns are moderately wide apart; but when the intercolumniations are small compared with their height and the diameter of the columns, their distance from the walls in porticoes must be increased, otherwise these would be much too narrow for their height, affording shelter neither from the sun's rays nor from the rain. On this account, under such circumstances, they may be set from the walls two or three times the distance between the axes of the columns. From this arrangement will result an agreeable and suitable proportion between the parts.

2840. The ceiling of a portico may be level with the under side of the architrave, or it

may be sunk the depth of the architrave, which may return in a direction towards the walls, thus forming sunk panels in the ceiling, or the sinking of the panels may be as much as the whole height of the entablature, whose mouldings should then be carried round them. When several ranks of columns occur in a portico the central part is sometimes vaulted, the two central columns of the width being omitted. The method of disposing pilasters in respect of their diminution has been treated of in a former part of this work. (2671, *et seq.*)

2841. The exterior walls which enclose the building should run as much as possible in straight continued lines from one angle to another; a straight line being the shortest that can be drawn. The internal walls, which serve for subdividing the building into its several apartments, should, as much as may be, extend from one side to the opposite one. Where they are intercepted by openings, they should be connected again above by lintels or other means.

2842. In *fig. 1017.* is shown the method of forming a plan or horizontal distribution, and combining it with the vertical distribution in the section and elevation. The thing is so simple that it can hardly want explanation. The equidistant parallel axes being drawn and cut at right angles by similarly equidistant ones, the walls, according to the required accommodations, are placed centrally upon the axes; and the columns, pilasters, &c. upon the intersections of the axes. The doors, windows, niches, and the like are then placed centrally in the interaxes, which must be bisected for that purpose. Above and below the horizontal combination the section and plan are to be drawn. These vertical combinations are infinite, and from every plan many sections and elevations may be formed. The figure exhibits a building of one story only, with a central apartment occupying the height of two stories. But on the same plan a building of two or more stories may be designed. These may have two tiers of porticoes, one above the other, or one only on the ground story, forming by its covering a terrace on the first floor; or a portico might receive on its columns the walls of the next story, and thus become recessed from the main front. So, again, the stories may be equal in height, or of different heights, as circumstances may require. The most usual practice is, above a basement to make the succeeding story higher; but above a principal floor the height of succeeding ones is diminished. The method of placing orders above orders does not require that any addition should be made to what has been said on that subject in Chap. I. Sect. 11. of this Book, and by the same methods arcades over arcades may be conducted.

2843. Not the least important of the advantages resulting from the method of designing just submitted to the reader is the certain symmetry it produces, and the prevention, by the use of these interaxial lines on each floor, of the architect falling into the error of false bearings, than which a greater or more dangerous fault cannot be committed, more especially in public buildings. The subterfuge for avoiding the consequence of false bearings is now a resort to cast iron, a material beneficially enough employed in buildings of inferior rank; but in those of the first class, wherein every part should have a proper point of support, it is a practice not to be tolerated. Neither should the student ever lose sight, in respect of the ties he employs in a building, of the admirable observation of Vignola on the ties and chains proposed by Tibaldi, in his design for the baptistery at Milan: "Che le fabbriche non si hanno da sostenere colle stringhe;"—Buildings must not depend on ties for their stability. The foregoing figure is from Durand's *Précis d'Architecture*. We now submit, in *fig. 1018.*, an illustration of the principles of interaxial division from the celebrated and exquisite Villa Capra, near Vicenza, by Palladio, wherein it will be seen, on comparing the result with what has actually been executed, how little the design varies from it. It will from this also be seen how entirely and inseparably connected with

Fig. 1017.

the horizontal are the vertical combinations in the section and elevation, the voids falling over voids, and the solids over solids. Whatever the extent of the building, if it is to be regular and symmetrical in its composition, the principles are applicable, and that even in buildings where no columns are used; for, supposing them to exist, and setting out the design as though they did exist, the design will prove to be well proportioned when they are removed. The full application of the principles in question will be seen in the works of Durand, the *Précis et Cours d'Architecture*, which we have used freely; and where we have had the misfortune to differ from that author, we have not adopted him.

2844. The student can scarcely conceive the infinite number of combinations whereof every design is susceptible by the employment of the interaxal system here brought under his notice; neither, until he has tested it in many cases, will he believe the great mastery in design which he will acquire by its use. In the temples and other public buildings of the ancients, it requires no argument to prove that it was the vital principle of their operations, and in the courts, cavædia, &c. of their private buildings it is sufficiently obvious that it must have been extensively used. That its use in the buildings of those who are called the Gothic architects of the middle ages was universal, a glance at them will be sufficient to prove. The system of triangles which appears to have had an influence on the proportions of the early cathedrals may be traced to the same source (see the early translation of Vitruvius by Cæsar Cesarianus), and indeed, followed up to that source, would end in the principle contended for.

2845. It is impossible for us to prove that the interaxal system was that upon which the revivers of our art produced the astonishing examples many whereof are exhibited in our First Book; neither can we venture to assert that it was that upon which our great master Palladio designed the example above given, unquestionably one of his most elegant works; but, to say the least of the coincidence which has been proved between the actual design and the theory upon which it appears to have been founded, it is a very curious, and, if not true, a most extraordinary circumstance. Our belief, however, is, that not only Palladio but the masters preceding him used the system in question, and that is strengthened by the mode (not strictly, we allow, analogous) in which Scamozzi, in the tenth chapter of his third book, directs the student to adopt in buildings seated on plots of ground whose sides are irregular.

2846. To Durand, nevertheless, the public is greatly indebted for the instruction he has imparted to the student in his *Précis d'Architecture* more especially, and we regret that in our own country the art is treated by its professors too much in the manner of a trade, and that the scramble after commissions has prevented their occupation upon works similar to those which have engaged the attention of professors on the continent. The fault, however, is perhaps not, after all, so much attributable to them as to a government, whatever the party in power, till within the last five years (nay perchance even now) totally indifferent to the success of the fine arts, whose palmy days here were under the reign of the unfortunate Charles. Our feelings on this subject, and love for our art, betray us perchance too much into expressions unsuitable to the subject under consideration, and thereon we entreat, therefore, the patience of our readers, knowing "we have a good conscience."

2847. Our limits preclude the further enlargement on this part of the subject, which in

FIG. 1015

detail would occupy the pages of a separate work, and which, indeed, from its nature, could not be exhausted. We trust, however, enough has been given to conduct the student on the way to a right understanding of this part of the laws of composition.

## SECT. V.

### SUBDIVISIONS AND APARTMENTS OF BUILDINGS AND THEIR POINTS OF SUPPORT.

2848. The subdivisions, apartments, or portions whereof a building consists are almost as many as the elements that separately compose them: they may be ranked as porticoes, porches, vestibules, staircases, halls, galleries, salons, chambers, courts, &c. &c. All these are but spaces enclosed with walls, open or covered, but mostly the latter, as the case may require. When covered, the object is accomplished by vaults, floors, terraces, or roofs. In some of them, columns are employed to relieve the bearing of the parts above, or to diminish the thrust of the vaulting. The horizontal forms of these apartments — a general name by which we shall designate them, be their application what it may — are usually squares, parallelograms, polygons, circles, semicircles, &c.; their size, of course, varying with the service whereto they are applied. Some will require only one, two, or three interaxal divisions; others, five, seven, or more. It is only these last in which columns become useful; and to such only, therefore, the system is usefully applied. The parts whereof we speak may belong to either public or private buildings: the former are generally confined to a single story, and are covered by vaults of equal or different spans; the latter have usually several stories, and are almost invariably covered with roofs or flats.

2849. When columns are introduced into any edifice to diminish the action of the vaults and increase the resistance to their thrust, the choice of the species of vault must be well considered. If, for example, the vault of a square apartment (*fig. 1019.*) of five interaxal

Fig. 1019.

Fig. 1020.

Fig. 1021.

divisions be covered with a quadrangular dome, or, in other words, a quadrantal cove, mitred at each angle, twelve columns would be required for its support. If the vault were cylindrical (*fig. 1020.*) eight columns only would be necessary; but if the form of the covering be changed to the groined arch (*fig. 1021.*), four columns only will be required. Supposing a room of similar form on the plan contained seven interaxal divisions each way, twenty columns must be employed for the coved vault, twelve columns for that whose covering was semi-cylindrical, and still but four for the groined vault. It is obvious, therefore, keeping economy in mind, that the consideration and well weighing of this matter is most important, inasmuch as under ordinary circumstances we find it possible to make four columns perform the office of twelve and even twenty. Here, again, we have proof of the value of the interaxal system, whose combinations, as we have in the previous section observed, are infinite. But the importance of the subject becomes still more interesting when we find that economy is inseparable from that arrangement whose adoption insures stability and symmetry of the parts. These are considerations whereof it is the duty of the architect who values his reputation and character never to lose sight. If honour guide him not, the commission wherewith he is intrusted had better have been handed over to the mere builder, — we mean the respectable builder, who will honestly do his best for his employer.

2850. What occurs in square apartments occurs equally in those that are oblong, for the first or square is but the element of the last. If it happen that from the interaxal divisions contained in the length of an oblong or parallelogram, the subdivisions will not allow of three bays of groins, it does not follow that the arrangement must be defective, for one may be obtained in the middle bay. In subdivisions of width, allowing five interaxes, at least four columns would be saved, and in those of seven interaxes eight columns might be dispensed with. (See *fig. 1022.*)

2851. When the subdivisions on the plan, supposing it not square, take in five interaxes wherein the longitudinal extent of the apartment include several bays of groins, whose number must always be odd, one column is sufficient to receive each springing of the arch, but in those of seven interaxal divisions two columns will be necessary. (See *fig. 1023, A.*)

2852. If the vaulting be on a large scale, its weight and thrust are necessarily increased,

and the columns may be changed into pilasters connected with the main walls, as in *fig. 1024.*, or as II in the preceding figure.

2853. The height of the apartment from the floor to the springing of the arches will be found three interaxes in apartments whose horizontal combination is of five interaxes, and four and a half for the height to springing of such as are of seven interaxial divisions on the plan. Where the combinations are different in the adjoining apartments the heights just mentioned afford the facility of lighting the larger one above the crown of the lower one, as at B in *fig. 1023.*

Fig. 1022.

Fig. 1024.

Fig. 1025.

2854. Sometimes the springing is from the walls themselves, as at C, *fig. 1023.*, instead of from the columns as at L. The first of these arrangements should be permitted only when *en suite* with the apartment there is another, D, wherein the springings are from columns. When the apartment is the last of the suit, the springings must be from piers or columns, one interaxis at least from the wall. If all these matters are well understood, as also the sections upon the orders, and upon the different elementary parts of a building, a graphic combination has been established by which we shall be much aided in the composition or design of all sorts of buildings, and enabled, with little trouble, and in a much shorter period of time than by any other process, to design easily and intelligently. To do more distinguishes the man of genius from the man who can be taught only up to a certain point.

## SECT. VI.

### COMBINATION OF THE PARTS IN LEADING FORMS.

2855. Having shown the mode whereby the parts of a building are horizontally and vertically combined in the several apartments, which may be considered the grammar of composition, we shall now show its application in the leading forms or great divisions of the plan. Keeping in mind the advantage, upon which we have before touched, of arranging the walls of buildings as much as possible in straight lines, we should also equally endeavour to dispose the principal apartments on the same axes in each direction. Upon first thoughts the student may think that a want of variety will result from such arrangement, but upon proper reflection he will in this respect be soon undeceived. The combinations that may be made of the different principal axes are, as above stated, numberless, that is, of those axes whereon the parts may be advantageously placed so as to suit the various purposes to which the building is destined, paying also due regard to the nature of the ground whereon the fabric is to be erected.

2856. Let us, for example, take a few only of the combinations which may be formed from the simple square, as in the first sixteen diagrams of *fig. 1025.*, by dividing it in both directions into two, three, and four parts. The thick lines of the diagrams may be considered as representing either walls or suits of apartments, in which latter case the open spaces between them become courts. In reference also to the vertical combinations connected with the dispositions in question, some parts of them may consist of one, other parts of two and three stories, as well for additional accommodation of the whole building to its purpose as for producing variety of outline in the elevation. If, as in some of the diagrams, we omit some of the axes used for the division, such omissions produce a new series of subdivisions almost to infinity. By this method large edifices may be most advantageously designed; it enables us to apply to the different leading axes the combinations suitable to the destination of the building. Considered however as merely an exercise for the student, the use of it is so valuable that we do not believe any other can be so beneficially employed by those masters who profess to teach the art. We have not gone into the subdivisions of the circle in detail, contenting ourselves with the two most obvious dispositions. These are susceptible of as great variety as the square, observing however that the leading axes must be concentric.

2857. Following up the method just proposed, let us imagine a design consisting of a certain number of similar and dissimilar parts placed in certain relations to each other. Now, having fixed clearly in our mind the relative situations of the several parts and the mode by which they are connected with each other, we shall have a distinct perception of the work as a whole. We may abbreviate the expression of a design by a few marks, as in *fig. 1026.*, wherein the crosses represent square apartments, and the simple lines are the expressions of parallelograms, whose relative lengths may be expressed by the lengths of the lines. The next step might be to expand these abbreviations into the form given in *fig. 1027.*, on which we may indicate by curves and St. Andrew's crosses, as dotted in the diagram, the way in which the several apartments are to be covered.

2858. We may now proceed with the design; but first it will be well to consider one of the apartments, for which let one of the angles B be taken (see *fig. 1027.* and 1028.). Suppose it, for instance, to be five

or any other number of interaxal parts square. This, then, will be the width of the apartments whose forms are that of a parallelogram; and inasmuch as in this apartment the diameter of the vault will be diminished by two interaxes, which results from the use of the four angular columns, the groined vault will be of the width of three interaxes, and the same arrangement will govern the rest of the apartments. In the centre an open court is attendant on the disposition, as indicated by the diagram. The section which is the result of the combination, subject however to other regulation in the detail, is given under the plan of the figure, and the elevation above it entirely depends upon, and is regulated by, the joint combination of the plan and section. The example is given in the most general way, and with the desire of initiating the student in the theory of his art. The building here instanced might serve some public purpose, such as a gallery for the reception of painting or sculpture, or at least give the hint for one; but our object is not to be misunderstood, — we seek only to give the tyro an insight into the principles of composition.

2859. It is not our intention to enter further on the variety which follows the method of designing, of which the foregoing are only intended as hints; but we cannot leave the subject without submitting another example for the study of the reader. Our desire is that of establishing general principles, whereof *fig. 1029.* is a more complete illustration than those that have preceded it. The abbreviated form of the horizontal disposition is shown at A, and in B it is further extended, and will be found to be very similar to that of No. 15. in *fig. 1025.* In the example the interaxal divisions are not drawn through the

Fig. 1025.

Fig. 1026.

Fig. 1027.

Fig. 1028.

Fig. 1029.

plan, but it will be immediately seen that the space allotted to the whole width of the apartments is three in number. In the centre a circular apartment is introduced and covered with a dome, which might have been raised, in the vertical combination, another story, and thus have added more majesty to the elevation. And here we repeat, that in

Fig. 1030.

designing buildings of more than one story, (for it cannot be too often impressed on the mind of the student,) the combination of the vertical with the horizontal distribution will suggest an infinite variety of features, which the artist may mould to his fancy, although it must be so restrained as to make it subservient to the rules upon which fitness depends.

2860. We close the chapter, not without regret, (because the subject is pleasant to us, but a treatise would not fully carry out the principles inculcated,) with an example from Durand in perspective. The general plan, A, *fig.* 1030., will be found similar to No. 11. in *fig.* 1025., and the distribution may be a good practice for the student to develop. It is an excellent example for exhibiting of what plastic nature are the buildings which the vertical combinations will admit as based on those which are horizontal.

## CHAP. III.

### PUBLIC BUILDINGS.

---

#### SECT. I.

##### GENERAL OBSERVATIONS ON PUBLIC AND PRIVATE BUILDINGS.

2861. THIS chapter will be devoted to such remarks on public and private buildings as may be necessary to guide the architect in their general composition. To enter into a detail of each would be impossible, neither indeed could it be useful, for there are rarely two buildings destined to the same purpose which could be erected exactly similar. More or less accommodation may be required in one than another. The site may not be suitable for the reception of similar buildings. A city will require very different buildings as to magnitude from those necessary for a town, besides many other considerations which will immediately occur to the reader.

2862. In designing public and private buildings the first object of the architect is to make himself acquainted with the uses for which the building is destined, and the consequent suitableness of the design for its purpose. He must enter into the spirit which ought to pervade the building, examining and adjusting with care those qualities which are most essential to the end proposed. Thus, though solidity be an essential in all buildings, it is more especially to be attended to in lighthouses, bridges, and the like. In hospitals, not only must the site be healthy, but the interior must be kept wholesome by ventilation and other means. In private houses almost everything should be sacrificed to the convenience and comfort of the proprietor. Security is an essential in the design and construction of prisons. Cleanliness in markets and public slaughter-houses, which we hope will, on every account, be ultimately established in suburbs, and not in the heart of every great town of the empire. Stillness and tranquillity should be provided for in places of study; cheerfulness and gait must be the feelings with which the architect arranges places of public amusement. The next step will be to consider whether the building should consist of a single mass, and whether it will be necessary that the whole should be solid, or whether it should open interiorly on one or more courts or quadrangles; whether the different solid parts should communicate with or be separate from each other. He must also consider whether the building will abut immediately on the public way, or be placed away from it in an enclosure; whether, moreover, all the solid parts should or should not have the same number of stories.

2863. From the whole the architect must pass to the different parts or divisions, determining which of them should be principal and which subordinate; which should be near and which distant from each other, and consequently their relative places and dimensions; how they should be covered, whether by vaulting or flooring; if the former, what species of vault should be selected, and whether the bearing of the timbers or the extent of the vault will require the aid of intermediate columns. Under these considerations, the sketch being made, the interaxal divisions of each apartment set out and written thereon, the architect may add them together, and thus ascertain the whole number of interaxal divisions, so that he may see that they can be contained on the given site. This done, he should take care that none of the interaxes are too wide or too narrow compared with the scale. Should that be the case, the number of interaxal divisions must be increased or diminished accordingly, either throughout or in those parts wherein the arrangement is defective.

2864. As the number of interaxes is greater or less in the apartments, so we may now determine the order to be used below the springing of the arches. On a sketch thus

conducted we shall have little more to do than to determine the profiles, ornaments, and other detail that the edifice requires. The student, by pursuing the course thus pointed out, will soon find his progress much advanced in the facility and success of designing. It is the course indicated by common sense as much in the study of the art as in the composition of designs, both of which are but an uninterrupted series of observations and reasonings.

## SECT. II.

### BRIDGES.

2865. Unless the design for a bridge be triumphal (a species now quite out of use), the composition can scarcely possess too much simplicity. If, indeed, in the design of a bridge we strictly adhere to the principles which regulate its convenience, stability, and economy, it will possess every beauty that can be desired. It is clear, therefore, that all applications of columns to the piers of bridges will fall under our severest censure. They can be of no service to the fabric, and are therefore unsuitable and absurd; their use moreover is a great waste of money, hence they are violations of an economical disposition in the design. We may, for illustration sake, point to the last bridge of importance erected in this country, viz. London Bridge, which is well and properly designed in comparison with Waterloo Bridge, which, though not behind the other in the requisites of strength and solidity, is inferior in the unfortunate application of columns to its piers. Had they been omitted, the deserved reputation of the engineer under whose designs it was executed would have been greatly increased, were his reputation and well-earned fame in jeopardy. The same comparison may be made between the bridge at Neuilly and that of Louis XVI., now the bridge *de la Concorde*. In the last decoration is attempted, in the former it is avoided: the last is hideous, the first agreeable.

2866. There are certain rules respecting bridges which must not be lost sight of, whereof the principal one is, that their direction must, if possible, be at right angles to the stream, and in the line too of the streets which they connect on the opposite banks of the stream. From a want of regard to these points many unfortunate blunders have been committed, which a prodigal expenditure of public money will not afterwards rectify, as we have seen in the operations consequent on the rebuilding of London Bridge. We allude to this point without the intent of blaming the parties concerned, but rather as a beacon to warn future authorities of the rock on which they may be wrecked.

2867. We had almost determined not to have introduced the section now under our pen, from the circumstance of the course of employment of the architect having latterly been so changed in favour of the engineer; but on reflection we have thought it proper, however short the notice, to say at least a little on the subject, which may be useful, from the engineer, strictly speaking, having but rarely the views in his designs of an accomplished artist; and we say this without the smallest feeling against or disrespect to the very able body of men called engineers in this country. On the equilibrium of arches and their piers, which are the chief parts of a bridge, we have in a previous part of the work already spoken, and so far explained our views on those points as to render further discussion here unnecessary. In most of the bridges of the ancients the arches were semicircular, in those of modern date they have been segmental or semi-elliptical. The last two forms are very much more suitable, because of the freer passage of the stream, especially in the case of floods.

2868. In the bridge at Pavia, over the Tesino, which is of an early period, and also a covered bridge, (a practice useless perhaps, but not uncommon in Italy and other parts of the Continent,) the arches are pointed; a form very favourable in every respect, and most especially so in rivers subject to sudden inundations, but unfavourable certainly in cases where the span of the arch is required to have a large width in proportion to its height. But the bridge just named has no common comparison with the ancient bridge. The effect resultant from its disposition is nevertheless satisfactory and magnificent, which abundantly proves that forms and proportions have less influence in producing beauty than have the qualities of propriety and simplicity.

2869. The position of a bridge should be neither in a narrow part nor in one liable to swell with tides or floods, because the contraction of the waterway increases the depth and velocity of the current, and may thus endanger the navigation as well as the bridge itself. It is the common practice, except under extraordinary circumstances, to construct bridges with an odd number of arches, for the reason, among many others, that the stream being usually strongest in the middle, egress is there better provided by the central arch. Further, too, if the bridge be not perfectly horizontal, symmetry results by the sides rising towards the centre, and the roadway may be made one continued curve. When the roadway of a bridge is horizontal, the saving of centring for the arches is considerable, because two sets of centres will be sufficient for turning all the arches. If, however, the bridge be

higher in the middle than at the extremities, the arches on each side of that in the centre must diminish similarly, so that they may be respectively symmetrical on each side of the centre. From this disposition beauty necessarily results, and the centring for one of the sides equally suits the other. A bridge should be constructed with as few arches as possible, for the purpose of allowing a free passage for the water, as well as for the vessels that have to pass up and down the stream, not to mention the saving of materials and labour where the piers and centres are fewer in number. If the bridge can be constructed with a single arch, not more should be allowed. The piers must be of sufficient solidity to resist the thrust of the arch, independent of the counter thrust from the other arches; in which case the centring may be struck without the impendent danger of overturning the pier left naked. The piers should also be spread on their bases as much as possible, and should diminish gradually upwards from their foundations. The method now usually employed for laying the foundations is by means of coffer-dams, which are large enclosures formed by piling round the space occupied by the pier so as to render it water-tight, after which the water is pumped out, and the space so enclosed kept dry till the pier is built up to the average level of the water. When, however, the ground is loose, to the method mentioned recourse cannot so well be had; and then caissons must be employed, which are a species of flat-bottomed boat, wherein the pier is built up to a certain height and then sunk over the place where it is intended to remain, the bed of the river having been previously dredged out to receive it, or piles driven on which it may lodge when the sides of the chest or caisson are knocked away. The centre should be so constructed as to be unsusceptible of bending or swerving while the arches are in the course of construction, or its form will be crippled. We have diverged a little from the limits by which this section should have been circumscribed, because no other place in the work allowed us to offer the practical observations here submitted to the reader.

### SECT. III.

#### CHURCHES.

2870. The churches whereof we propose speaking are not such as the present commissioners for building churches in this country sanction, but true good churches, such as appeared here under the reign of Queen Anne; true honest churches, one whereof is better than a host of the brick Cockney-Gothic things that are at present patronised, wherein the congregations are crammed to suffocation and not accommodated. These, therefore, we shall leave to the care of the peculiar school in which they originated, and the society to whom they more properly belong, to speak of buildings that deserve the name. Neither do we think it useful to inquire into the designs of the temples of the ancients, seeing that paganism has passed away, never to return. The largest of these temples compared to the cathedrals of the moderns was but a small affair.

2871. The early Christian worship, attended by large congregations, required for its exercise edifices whose interiors were of great extent and well lighted. Nothing was so well adapted for the purpose as the basilicæ, which, bearing the name from their resemblance to the ancient courts of justice, were raised for the purpose. Such was that of St. Paul without the walls of Rome (*figs. 141. and 142.*), the ancient St. Peter's, and many others. That of S. Giovanni Laterano was divided by four ranks of columns, which supported the walls, carrying the roofs of five aisles formed by the ranks of columns, the middle one or nave being wider and higher than the others. Each aisle being lower than that adjoining parting from the centre, admitted lights to be introduced in the several walls. The direction of the length of the nave and aisles was from east to west, and was crossed by a transverse nave called a transept from north to south. In front an ample porch or portico was provided for the assembling of the people, and for their shelter from the seasons. The distribution we have just described was, as we have mentioned in an earlier part of this work, the type of the Gothic cathedral, though it passed through two or three steps before the adaptation assumed the magnificence that would have been displayed in the church at Cologne had that structure ever been completed.

2872. The portico we consider essential to any building which deserves the name of a church, not less on account of the beauty it imparts to the edifice than for its use.

2873. The use of the modern church being the same as that of the first Christian basilicæ, it may be doubted whether for extremely large assemblies a better disposition could be chosen. The desire, however, of novelty, says Durand, induced Bramante to imitate the temple of Peace in the design for the new church of St. Peter, although that building was less a temple than a public dépôt or treasury destined by Vespasian to receive the spoils from Judea. The desire, moreover, continues that author, of surpassing the ancients, by gathering into a single edifice the beauties of several, induced the same architect to

crown the edifice imitated from the temple of Peace with another, imitated from the Pantheon; and in this country the same sort of thing was done by Wren in St. Paul's.

2874. It is easy to perceive that these buildings are not so well calculated for worship as the ancient basilicæ. The obstruction to seeing and hearing caused by the large piers of the modern churches is a great defect when compared with the little obstruction that the columns of the basilica present. But this is not the only blemish in the cathedral of Italian origin, as may be shown from the fact of basilicæ of the time of Constantine being still in existence; whilst the church of St. Peter, erected long posterior to that period, would in this day have been a heap of ruins, but for the enormous repairs constantly bestowed on the fabric, and the iron chains with which the dome has been girt. The cost is another serious objection to them, most especially in the construction of their domes, which are, with their tambours, buildings deficient in real solidity, from the large portion of false bearing they must involve; creating a very different sensation to that experienced in viewing the *louvre* of a Gothic cathedral, to which, without being insensible to the beauties of St. Peter's, St. Paul's, and other buildings of the class, we do not hesitate to give the preference.

2875. The facilities of designing a church on the principle of the basilica will be obviously those of interaxial divisions, and will not require further developement. The same method will be useful in designing the smaller parish church, with its nave and an aisle on each side, which is not only the most economical, but the best form. It was that which best pleased Sir C. Wren, whose churches are generally so planned; and we shall here give a short account of one of his best of this form, that of St. James's, Westminster, whose interior is worthy of all praise. It is an excellent example of Wren's love of harmony in proportions; the breadth being half the sum of its height and length, its height half its length, and its breadth the sesquialtera of its height: the numbers are 84, 63, and 42 feet. The church is divided transversely into three unequal parts, by a range of six columns on each side the nave, forming aisles which are each one fifth of the whole breadth, the remaining three fifths being given to the breadth of the nave. The roof is carried on these columns, and is as great a proof of the consummate skill of the architect as any portion of the fabric of St. Paul's, on account of its extreme economy and durability. It is not further necessary to describe the building; but the observations of the architect upon it are of the utmost value, emanating from such a man, to the church-builders of the present day, if it be possible to reclaim them from their pasteboard style. "I can hardly think it possible," says our architect, "to make a single room so capacious, with pews and galleries, as to hold above two thousand persons, and all to hear the service, and both to hear distinctly and see the preacher. I endeavoured to effect this in building the parish church of St. James's, Westminster, which, I presume, is the most capacious, with these qualifications, that hath yet been built; and yet at a solemn time, when the church was much crowded, I could not discern from a gallery that two thousand were present. In this church I mention, though very broad, and the middle nave arched up, yet as there are no walls of a second order, nor lanterns, nor buttresses, but the whole roof rests upon the pillars, as do also the galleries, I think it may be found beautiful and convenient, and, as such, the cheapest of any form I could invent." On the place of the pulpit in a church of this class, the same architect continues: "Concerning the placing of the pulpit, I shall observe, a moderate voice may be heard fifty feet distant before the preacher, thirty feet on each side, and twenty behind the pulpit; and not this, unless the pronunciation be distinct and equal, without losing the voice at the last word of the sentence, which is commonly emphatical, and if obscured spoils the whole sense. A Frenchman is heard further than an English preacher, because he raises his voice, and not sinks his last words. I mention this insufferable fault in the pronunciation of some of our otherwise excellent preachers, which schoolmasters might correct in the young, as a vicious pronunciation, and not as the Roman orators spoke: for the principal verb is in Latin usually the last word; and if that be lost, what becomes of the sentence?" Speaking of the dimensions of a church, the following are Wren's own words, after stating that a proposed church may be 60 feet broad, and 90 feet long, "besides a chancel at one end, and the belfry and portico at the other." "These proportions," he says, "may be varied; but to build more room than that every person may conveniently hear and see, is to create noise and confusion. A church should not be so filled with pews, but that the poor may have room enough to stand and sit in the alleys, for to them equally is the gospel preached. It were to be wished there were to be no pews, but benches; but there is *no stemming the tide of profit*, and the advantage of pew-keepers; especially, too, since by pews in the chapels of ease the minister is chiefly supported." We shall close the section by the following quotation from the same admirable artist. Quaint though the language now seem, and simple as the mind of the writer, it is of great value, and would be respected by any but commissioners for building churches. "As to the situation of the churches, I should propose they be brought as forward as possible into the larger and more open streets, not in obscure lanes, nor where coaches will be much obstructed in the passage. Nor are we, I think, too nicely to observe east or west in the position, unless it falls out

properly: such fronts as shall happen to lie most open in view should be adorned with porticoes, both for beauty and convenience; which, together with handsome spires or lanterns, rising in good proportion above the neighbouring houses, (of which I have given several examples in the city, of different forms,) may be of sufficient ornament to the town, without a great expense for enriching the outward walls of the churches, in which plainness and duration ought principally, if not wholly, to be studied." Such are the common-sense remarks of a man of whom this country has to be proud, but who died neglected, the common fate of all artists who do not minister to the vanity of their employers.

2876. Churches are usually constructed on the plan of a *Greek cross*, which is that wherein the length of the transverse part, or transept, is equal to that of the nave; of a *Latin cross*, wherein the nave is longer than the transept; *in rotondo*, where the plan is a circle; *simple*, where the church has only a nave and choir; *with aisles*, when a subdivision occurs on each side of the nave; and those with aisles, as we have above seen, may have more than one of such aisles on each side of the nave.

#### SECT. IV.

##### PALACES.

2877. We regret that in this country we can offer no model of a palace for the student. Windsor Castle, with all its beauties, which however consist more in site and scenery than in the disposition of a palace, will not assist us. A palace is properly an edifice destined not only for the residence of the sovereign or prince, but for the reception also of persons who have the privilege of public or private audience. It being impossible for the whole of the parties to be present together, besides the apartments which are occupied by the sovereign and his family, there must be ample room and apartments for the attendants in waiting of every degree, and the consequent accessories. A palace should be disposed with porticoes, vestibules, galleries, halls of waiting suited to every season, wherein those to be admitted may wait with convenience and comfort till their turn of admission arrives. It is evident that, from the nature of such an edifice, much magnificence should be displayed in it. The palaces of the Escorial, Versailles, and the Tuileries are, though extremely spacious, and consequently imposing, but ill disposed and imperfect examples of a palace. Perhaps the most perfect in Europe is that of the King of Naples at Caserta, commenced in 1752, which is described by Milizia as follows:—"The plan of this palace is a vast rectangle, 731 feet long from east to west, 569 from north to south, and 106 feet in height. The interior is divided into four courts, 162 feet by 244. The depth of building that surrounds these courts, in which are the apartments, passages, &c., is 80 feet, including the thickness of the walls, which are in some instances 15 feet. The two principal façades have five stories besides that below the ground, and each contains thirty-seven windows. There are three entrances, one in the centre, and the others at equal distances between it and the extreme angles, where, as well as in the centre, the building breaks forward a little, is carried up to the height of 60 feet, and formed into pavilions by columns 42 feet high. Thus the whole height of the building is 102 feet from the foundation to the top of the pavilion, at the angles 162 feet, and in the centre 190 feet. The basement, which is rusticated, comprises the lower offices, the ground floor and its mezzanine. Above is placed an Ionic order of columns and pilasters, which contains the two ranges of state apartments; the lower windows are ornamented with pediments; in the frieze are introduced the windows of the upper mezzanine. The centre entrance leads to a superb portico, which traverses the building from north to south, and is sufficiently spacious to allow carriages to pass under from either façade to the centre of the building, where is a large octangular vestibule, which unites the arms of the cross produced by dividing the plan into four courts: two sides of the octagon are open to the portico, four to the four courts, one to the grand staircase, and the eighth is occupied by a statue of Hercules crowned by Virtue, with this inscription:—

'Virtus post fortia facta coronat.'

2878. "The grand staircase, which is on the right, is lighted by twenty-four windows, and decorated in a beautiful style. At the first landing it is divided into two flights; the hundred steps of which it is composed are 18 feet long, and each of one piece of marble; it is lighted also from the top by a double skylight. The upper vestibule is also octangular, and surrounded by twenty-four columns of yellow marble 18 feet high. Four doors lead from thence to the apartments, the one opposite the landing to the chapel, that to the right to the apartments of the king, which comprehend the south-west angle of the building overlooking the sea and the plains of Naples and Capua. To the left are the apartments of the queen, occupying the north-west angle, the remainder of these floors being occupied by the princes. The chambers throughout are vaulted, and admirably arranged; the

apartments of the king and queen are separated by a gallery 138 feet long, 42 wide, and 52 high. The palace contains a small elegant theatre, on a circular plan, divided into nine compartments, with four tiers of boxes. The chapel is rectangular in its plan, with the end terminated semicircularly, and decorated with isolated Corinthian columns on pedestals, with an entablature, in which the cornice is not omitted. The marbles and sculptures throughout are of the richest kind; the apartments generally well arranged and distributed, of magnificent dimensions, and of various forms. The whole is a rare assemblage of vastness, regularity, symmetry, richness, ease, and elegance. The multiplicity of windows may certainly be a little at variance with propriety.

"But the most wonderful part of this grand work has not as yet been described. There are ranges of aqueducts of a great height, and of sufficient length to unite the two Tifati mountains near the Furche Caudine. The waters on the mountains are collected into a canal for the purpose of supplying these aqueducts, and conducted to various lakes and fountains of every description. To the embellishments," adds Milizia, "of this royal residence are added a convenience and solidity that throw into shade all that has been done before or since." The plans, &c. of this palace may be referred to in Durand's *Parallele des Edifices*.

2879. Great as this work is, it would not have eclipsed the palace at Whitehall projected by Inigo Jones, and published in Kent's *Designs*, (see fig. 207., *supra*.) had the edifice, whereof the banqueting-house is not the hundredth part, been carried to completion. This palace has already been described in the First Book of this work, in turning to which the reader will find that the proposed palace consisted of six courts, and, with greater beauties of composition, would have occupied a much larger site than the palace at Caserta.

2880. We have been diffuse in the description of the last-named palace, because it contains the leading, and, indeed, governing principles, upon which the palace for a sovereign should be constructed; and from the description, the student might almost be at once led to the design of such an edifice.

2881. The designs which Bernini made at the request of Louis XIV., instigated, no doubt, by his minister Colbert, (for they were both of them lovers and patrons of the fine arts,) for uniting the Tuileries and Louvre, would, had they been executed, added another palace to which the student might have been referred for information on the subject of palaces. They may be seen in Durand's "Parallel" above mentioned, and, we think, will bear out the propriety of reference; and we fully agree with Le Grand, except in the inflated language he adopts, that "Le gouvernement qui attachera son nom a cette execution sera proclamé grand dans la posterité; il honorera la nation par les arts en reunissant ainsi les beautés eparses, incomplètes de ces deux palais, pour n'en former qu'un seul, il s'assurera la gloire d'effacer par cette merveille celles dont, excepté les pyramides d'Egyptes l'existence n'est plus que dans l'histoire."

2882. It is almost unnecessary to observe, that the site on which a palace is to be seated must be open and free in every respect, that a large expanse of gardens should be attached to it for the use of the public as well as the sovereign, in which respect the palaces of the Tuileries and Versailles are unparalleled. All should have a royal bearing, parsimony being inadmissible in works of this nature.

## SECT. V.

### GOVERNMENT OFFICES.

2883. The offices of government should be designed consistently as regards their distribution and magnificence, with some respect to the power and importance of the nation for whose use they are to be constructed. Whilst on the Continent, and especially in Paris, some of the finest examples of art provide for the convenience of the different departments, the only building that can be named here in this respect are the offices at Somerset House, built by the late Sir W. Chambers. And herein so mean and indifferent to the arts has of late been every set of ministers in this country, that but for the appropriation of the eastern part of the site to a joint-stock college, it is probable the river front would never have been finished.

2884. The nature of the disposition of government buildings must of course depend on the particular department for which the building is destined, full information on which must be had in every particular before the architect can begin to imagine the building to be designed. The most ample space should be allotted to them, and no rooms for the performance of the duties attached to the department should be allowed above the first story over the ground floor. The public, indeed, ought not to have to ascend or descend even one flight of steps. The access to the different apartments should be spacious and easy;

the quadrangles, where they are necessary, should be ample, so as to afford abundance of light and air; porticoes should be provided for the shelter of the public who have to transact business, and the façades should be in a broad simple style.

2885. Without intending any affection of the fanciful style adopted by their architect, we would, in this country, point to the mode in which the offices at the Bank of England were disposed and planned by the late Sir John Soane, and the beautiful method of lighting, as highly valuable studies for the architect. The skill here exhibited by him, if not obscured by his successors, and the restless desire of change that the directors seem to exhibit, will be lasting monuments of that architect's ability, however disfigured his designs may have been by the caprice of their ornaments.

2886. The splendour of the government offices in this country seems, in every case, to be in an inverse ratio to the renown of the department. Thus, let the Admiralty be the example for consideration, and it would be difficult to decide which was worst, the interior or the exterior. On the Treasury jumble of buildings, it would be difficult to bestow a serious word. If the country be too poor to accomplish all the works at once which would be necessary for putting us in possession of buildings worthy the country, surely designs on a proper scale for rebuilding all these edifices might be made, and rigidly adhering to the designs approved after due consideration, portions might be annually executed, so as to distribute the outlay over a series of years. But we regret to say that we fear any hints under this section will be thrown away, while political parties are contending for power, and consider the comfort of the public and the promotion of the fine arts subjects of comparative insignificance. The source of the evil is in the nature of the constitution; and though, speaking as Englishmen, we do not wish to see that changed, yet we think a little more absolute power, under which there is invariably less jobbing, would be in some measure beneficial to the arts.

2887. We have hinted that there is no government building to which we should wish to refer the reader, Somerset House excepted. In Paris he will find an abundance of examples. The Admiralty there, a recent building of the most simple exterior, on which there are neither dolphins, tridents, nor anchors, as in that near Charing Cross, is a stupendous mass of building, well calculated for the narrow street in which it stands, to which it imparts unmeasured dignity. The *Garde Meuble*, as it was formerly called, in the Place de la Concorde (formerly de Louis XV.) is one of the most beautiful compositions in Europe. This is, perhaps, an example rather too florid for imitation (we do not mean in lines, but in spirit) in this country, though it is known that a well and richly-designed building costs little, if any, more than a bad, ill-digested one. The Mint of Paris is another of the French government offices worthy of the nation. But we need not multiply the instances, Paris being now almost as well known to the Englishman as London itself. It is, however, to be recollected that in France all the government buildings are of as much interest to the government in the provinces as in its metropolis, and that the great hospital at Lyons, by Soufflot, is not surpassed in Europe. In England, we know not one that approaches it.

## SECT. VI.

### COURTS OF LAW.

2888. A court of law in this country, speaking in more senses than one, but chiefly, here, to preserve the gravity of our work architecturally, is a building in which every one, whose business unfortunately leads him to it, sits in pain, the judges and counsel excepted. Attorneys, witnesses, jury, and audience, or public, are equally doomed to be pent up and cramped like the poor sheep at Smithfield, or a sailor in the bilboes, if that punishment be still in existence. The practice is infamous and inexcusable; it originates not with the architect, but with the government, which affords neither space nor money for the erection of courts suitable to the administration of justice, though the public are, by a pleasing assumption of the administrators of the laws, supposed to know all the decisions that take place in them, and treated by an answer to those that plead ignorance, which, but from the little of their proceedings that oozes out by that useful organ, the public press, would really be the case — “*Ignorantia non excusat legem.*” It came out in evidence before a committee of the House of Commons on the late rebuilding of the courts at Westminster, that Sir John Soane, their architect, was told by a chief of one of the courts then proposed to be built and since executed, that *his* court, as planned, would be quite large enough to hold all *that had any business there*; rather a strange dictum for a personage whose duty, sitting on the judgment-seat, was to tell the people that their unaffected ignorance of the laws he was sworn to administer was no excuse for violating the law which might bring them before him.

2889. We have thus prefaced our short observations on this section for the purpose of impressing on the mind of the architect who may be called on to furnish designs in the provinces (for in London there is not much chance of his employment on such an occasion), that there are other persons who have equal right to as good accommodation as the judges and the bar, who are extremely well paid for the duties they perform; the parties to which we allude being the jury who are to decide upon the evidence, the witnesses from whom such evidence is derived, the attorneys whose instructions to counsel are from instant to instant necessary for the proper conduct of a case, and, though last not least, the public, who have an undoubted right to be present, not only because they are entitled to instruct themselves, as the axiom requires, that they may not be ignorant of the law, but because, in this country, the conduct of the judge himself may be open to public opinion, and his character properly transmitted to posterity, and estimated by the public.

2890. After the foregoing remarks, we apprehend it will be scarcely necessary to impress on the mind of the architect the importance of providing an ample space for the audience or public, rooms for jurymen in waiting, and full space for the latter when they are placed in what is called their *box*, so that the pain of the body may not distract the mind from the evidence of the witnesses and the charge of the judge. The artist, therefore, must be careful to supply such accommodation as shall render the office of all parties engaged a pleasing duty rather than an irksome task.

2891. To every court of law should be attached a large vestibule or salon, sufficiently large to afford a promenade for those of all classes engaged in the courts. In Westminster, bad as the courts are, this is well provided in the magnificent room called Westminster Hall, to which had the courts that open on it been in character our opening observations had been spared. It is almost needless to observe that apartments and accommodation are to be provided for the robing and occasional refreshment of the judges, the bar, and the different officers attached to the court. In courts for the trial of felons it may be necessary, if the prison has no communication with the court, to add some few cells for securing criminals. This, however, will be dependent on the circumstance mentioned, and should be provided accordingly.

2892. In these, as in other buildings where there is often congregated a great number of persons, the entrances, and at the same time outlets, should be increased in number as much as convenience and the situation will permit; and another indispensable requisite is, that the court itself should be so placed in the design that no noise created on the outside of the building may be heard in the interior, so as to interfere with the attention of those engaged on the business before them.

2893. In the provinces the observations we have made may be of some use to the student, and on this ground we have thought it our duty to offer them.

## SECT. VII.

### TOWN HALLS.

2894. The town hall of a city or town will necessarily vary with their extent and opulence. In towns of small extent it should stand in the market-place; indeed, in a large proportion of the towns of this country the ground floor is usually on columns, and forms the corn market of the place, the upper floor being generally sufficiently spacious for transacting its municipal business. Where the sessions or assizes, as in cities, are held in the town hall, it is necessary to provide two courts, one for the civil and the other for the criminal trials; and in this case the observations on courts of law in the preceding section equally apply to this in that respect.

2895. In cities and corporations where much municipal business occurs, the number of apartments must of course be increased to meet the exigencies of the particular case; and, if possible, a large hall should be provided for the meetings of the corporation. A certain appearance of its being the property of the public is the character to be imparted to it, and this character must be stamped on the disposition as well as the elevation. Thus, on the ground floor of the first class of town halls, courts, porticoes, or arcades, and spacious staircases should prepare for and lead to the large apartments and courts of law on the first floor. Every means should be employed in providing ample ingress and egress to the persons assembling. Fire-proof rooms, moreover, should be always provided for the records and accounts belonging to the town. The exterior of the building should not be highly decorated, but designed with simplicity, yet with majesty, as it is an index to the wealth and importance of the place for whose use it is erected.

2896. For the disposition of these buildings the student may turn with profit to the examples abroad, in which, generally, apartments are provided for every branch of the

government of the city. Durand, in his *Parallèle des Edifices*, has given several examples, among which that of the city of Brussels is a beautiful instance of the application of Gothic to town architecture. It was commenced at the beginning and finished in the middle of the fifteenth century, having a tower and spire which, together, rise upwards of 360 feet from the level of the place. The interior of this edifice presents all the accommodations which are required for a municipality; and the principal façade, though a little disfigured by the tower not rising in the centre of it, is composed with great unity, harmony, and simplicity. Though rich, the ornaments are introduced with great order and symmetry, and the system of design pervading the front is by pyramidal masses, whose effect is exceedingly light though bold.

2897. The most celebrated of town halls in Europe is that of Amsterdam, erected during the first half of the seventeenth century by Van Campen. The design is given in Durand's *Parallèle*, and also forms the subject of a volume, in folio, published in Holland; the cost of its erection was more than thirty millions of florins, and the fabric stands, they say, on 13,659 piles, which were required from the marshy nature of the ground. The plan is nearly a square; it is 282 feet long and 255 feet wide, and its height is 116 feet. To describe the disposition of the plan would be impossible; it can only be comprehended by reference to it. The ground story in the principal façade forms the basement on which rises an order of Corinthian pilasters, containing two ranges of windows; then an entablature, and above that a repetition of similar pilasters, containing two ranges of windows. The latter are simple, having no ornament except a festoon between each range. At the angles are two pavilions, ornamented with four pilasters, and in the centre one with eight, which projects forward a little. On this a pediment rises ornamented with historical bas-reliefs, and thereover, more distant, is an elegant cupola for the clock. Instead of one large principal entrance there are seven small ones, alluding, as it is said, to the seven united provinces; and it is also pleasantly said that the smallness of the provinces are typical of the smallness of the doors.

2898. We cannot, however, laud the composition of this building, which, by the way, encloses the bank and public treasury. Its merit consists mainly in the disposition of the plan, the restraint in decoration, and the good construction of the work, whilst its imposing effect results from its magnitude as a mass. The use of the Corinthian and Composite orders for such a building was almost an abuse, for their proportions vary so little from each other as almost to create confusion between the two. Again, the similarity of the subdivision in the two stories, each divided into two ranks of windows, produces a cold monotony. The windows too, without architraves, have an effect as mean as the festoons which are introduced between the windows are insipid. Neither will the excuse given for the seven small doors justify the introduction of such poverty in a building whose dimensions are so great, besides their appearance seeming to give strength to the impression that they are only entrances to the basement story. The student, on the subject of town halls, may be referred also to those of Antwerp and Maestricht and Louvain. And here we cannot refrain from alluding to the works we noticed but a little time past in the restoration, and indeed completion, of the Hotel de Ville at Paris, first commenced in 1533 on the designs of François de Cortonne, in what is now called the style of the renaissance. The additions which became necessary in consequence of the extended business of the city are executing in the same style, and will present one of the most picturesque features of the city. Such an occasion as this is a legitimate one for the employment of the style of the renaissance, and not in the trumpery stuff that appears in this country, without any solid reason for its adoption. The interior of this building, with its court or quadrangle, is not without grandeur; and the interior distribution of it, with its beautiful staircase, is a sufficient proof that what the Germans and their admirers now denominate "aesthetics" in art was well understood and practised in Italy, France, and even England, on the renaissance, whilst their country, as respects architecture, was in a state of barbarism. We regret we have not the opportunity of referring to any town hall in England which meets in all respects what we deem the requisites of such a building. We do not say that none such exist, only that it has not come to our knowledge.

## SECT. VIII.

### COLLEGES.

2899. A college, which is an establishment for the education of young men, generally consists in this country of one or more courts or quadrangles, round which are disposed the rooms for the students, with the chapel, library, and eating hall; apartments for the head of the establishment and for the fellows; a combination room, which is a spacious apart-

ment, wherein the latter assemble after dinner; kitchen, buttery, and other domestic offices, laitrines, gardens, &c.

2900. In these particulars, we are speaking of English habits, for on the Continent the college is quite a different sort of thing. As, however, we consider the best instruction to the student will be concise information on those which exist, we shall shortly mention the most celebrated abroad and in England.

2901. At Rome, the college formerly that of the Jesuits, now the Roman College, is a very large edifice, simple in character, as this species of building seems to demand. Its length is 328 feet, and its height, without the attic, 87 feet. Two large gateways are placed in the middle compartment, and form the entrances to the building. In these there is nothing particularly to admire, nor in the façade generally, which is encumbered, from the nature of the edifice, with a great number of windows. The great quadrangle is, however, one of the finest in Rome, consisting of two stories of arcades, a distribution particularly applicable to buildings of this class, and which we are surprised has never found adoption in this country. In these galleries the different classes or lecture rooms are placed, under their divisions of literæ humaniores, rhetoric, and philosophy. Had the building been finished as Ammanati designed it, there would not have been in Italy a finer structure nor one more suitable to its destination. It has, by the alterations from the original plan, been much cut up; yet it is a magnificent pile of building, consisting of corridors, dormitories, gardens, refectories, and other accessories, which, with the church which forms a part of the plan, occupy a circuit of upwards of 1500 feet. The other buildings in Rome which pass under the name of colleges are not to be considered as establishments for education, being destined to the study of theology and other sciences: such are the Propaganda and the Sapienza, which last is one of the finest modern buildings of the eternal city.

2902. At Genoa is a magnificent college, which was formerly the palace of the Balbi family, by whom it was given to the Jesuits for a place of education; but, from the original destination of the building, it possesses none of the essential character which belongs to an edifice of this class.

2903. Paris, we believe, still contains nine colleges, hardly one whereof, says the author of the article "College" in the *Encyclopédie Methodique*, deserves notice. The same writer says that in England alone are found examples of what a college ought to be; and from all that we have seen on the Continent, we believe him to have come thereon to a correct conclusion.

2904. The universities of Oxford and Cambridge furnish a study for the architect in this class of building nowhere else to be found; and though the greater part of their colleges are extremely irregular in plan, they are generally convenient in disposition and highly picturesque in effect. In Oxford, the most regular in plan is Queen's College, and this is of modern construction, having been commenced as late as 1710, and in the Italian style. We are not, however, about to describe the style, which is not an example for study, but the disposition of the building. The principal front stands towards the High Street. The whole site on which the college stands is 300 feet by 220, which is divided by the chapel and hall on the right and left of the intervening building into two spacious courts. The south court, which is that nearest the street, is 140 feet long and 130 broad, having an arcade round it on the south, east, and west sides. Over that on the west side are two stories, which contain the apartments of the fellows, those of the provost, and a gallery communicating with the hall and common or combination room. The east side, which is uniform with that on the west, comprises the apartments for students of the society, and on the north side are the chapel and hall. The south side of the court or quadrangle has no dwelling in it, but is composed of a decorated wall, in whose centre is the great entrance, above whose arch an open cupola stands upon columns, and under the cupola the statue of Queen Caroline, the consort of George II. The interior court or north quadrangle is 130 feet by 90. On the north, east, and south sides are provided apartments for the members of the society, and the west is occupied by the library: the entrance to it is by a passage between the hall and chapel. The dimensions of the hall are 60 by 30 feet; those of the chapel are necessarily, as to width, the same, but it is 100 feet long. The library, which was completed earlier than the rest of the building, is 123 feet long and 30 feet broad. That the student may form an idea of the accommodation afforded on the site described, it may be taken as holding about 170 persons, including the provost and fellows, whose apartments, of course, occupy a considerable portion of the space. Hawksmoor is, as we believe, the architect; certainly, as far as we can judge, not Sir Christopher Wren, to whom some have attributed it.

2905. We have no intention to pursue the description of the colleges in either of the universities. We have selected the above as a model of disposition only, because, as we have hinted, it is in very bad taste: so bad, indeed, in that respect, as to be a model for avoidance. We shall, however, give a few more memoranda as to the parts of colleges in existence, here merely observing that a bed and sitting room, both of moderate dimensions, are as much as can be afforded to the students of the establishment.

2906. Of the colleges in Oxford, Christchurch is past question the most magnificent. Its extent, towards the street, is 400 feet. Its hall is 115 feet long, 40 feet broad, and 50 feet in height, and the entrance to it is by a very noble staircase. The chapel is the cathedral of Oxford, and is 154 feet long, and the breadth, including aisles, 54 feet. The great quadrangle is nearly 280 feet square, and this communicates with another called Peckwater quadrangle, of considerable dimensions, in which, on the south side, stands the noble library of the college, the upper room whereof is 141 feet long, 30 feet broad, and 37 feet high. At the side of and adjoining the last are the Canterbury quadrangle and Fell's Buildings, and on the other side the chaplain's quadrangle. What is called the Christchurch Meadow, attached, affords the most delightful walks for the exercise and recreation of the members, being bounded on the east by the Cherwell, on the south by the Isis, and on the west by a branch of the same river. The whole establishment is worthy of the princely founder, whose spirit seems still to reign in the conduct of those connected with it. Such a magnificent foundation cannot elsewhere be referred to.

2907. In Cambridge, the library and court of Trinity College, the former one of the finest works of Wren, and the extraordinary and beautiful chapel of King's College, are the principal features of the university. There are also some beautiful pieces of architectural composition; but as there is nothing we could select as a model for a college, which is the principal object of the section, we do not consider it necessary to detain the reader by an account of them. We may, however, mention that the chapel of King's College is 316 feet long, 84 feet broad, and 90 feet from the ground to the top of the battlements. Corpus Christi College is, perhaps, the last college in either of the universities that has been rebuilt; but in disposition, and most especially in design, it is rather an *index rerum vitandarum* than a model we should recommend to the student's attention.

## SECT. IX.

### PUBLIC LIBRARIES.

2908. Although a public library would seem to require a grave and simple style of treatment, it is, nevertheless, properly susceptible of much richness, if the funds admit, and it comports with the surrounding buildings to use much decoration. A public library may be considered as the treasury of public knowledge; indeed its treasures are even more important to society than the public treasures of gold and silver. It is also to be considered as a temple consecrated to study. Security against fire is the first important consideration in its construction; indeed that point ought to be deemed indispensable; and the next consideration for the accomplishment of its purpose is quietness. The first requires that no materials except stone, brick, and iron should be employed in the walls, floors, and roofs; and the last, that it should stand far removed from a public thoroughfare. Within, especially in this climate, there can scarcely be too much light, because there are always modes of excluding the excess in the brightest days of our short summers; and in the dark days of our winters no such excess can occur. Neither should the light be placed high up for the purpose of obtaining more room for the presses which are to receive the books, because even a greater space may be obtained, as in the magnificent library at Trinity College, Cambridge, by Wren, by making the presses stand against the piers at right angles with the longitudinal walls, and placing the windows between them. Moreover, the presses, when placed longitudinally against the walls, the windows being above, have the titles of the books they contain indistinct, from being too much in shadow. The library just mentioned is in every respect one of the finest works of Sir Christopher Wren. It stands on an open arcade, at the north end whereof is a vestibule, whence the ascent is by a spacious staircase to the library itself, which is 200 feet long, 40 feet wide, and 38 feet high, floored with marble, and decorated with pilasters and an entablature of the Corinthian order. Though this library is of no mean extent, we do not adduce it as an example of a large public library suited to a nation, but as a perfect model of the mode of distribution, which might be carried in principle to any extent. If the readers be very numerous, a reading room, of course, becomes necessary, which should be placed as centrally as may be to the whole mass of building, so that the labour of the attendants may be lessened, and the readers at the same time more readily served with the books wanting. The best mode of warming the apartments is by a furnace and boilers, not at all adjoining to or communicating with the building, but by carrying pipes round the apartments or in the floor, through which pipes a constant circulation of the boiling liquid is kept up, and from which a radiation of the heat takes place.

2909. The most ancient and celebrated library in existence is that of the Vatican; in the latter respect, as well on account of its size as of the number of valuable manuscripts it con-

tains : it occupies in the suite of its apartments one of the sides of the Vatican 900 feet in length. The presses containing the books are decorated with the finest specimens of Etruscan vases. The long gallery terminates at one end by the Museum Christianum and the Stanza de' Papyri, and at the other end by the new museum, with which it communicates by a marble staircase. The ante-salon to the library is about 200 feet long and about 87 wide. In the architecture or arrangement there is nothing particularly to admire, and indeed it was not originally intended for the purpose to which it has been appropriated.

2910. We do not think it necessary to stop the reader for an account of the Medicean library at Florence, though the work of Michael Angelo. Its proportions are grand, but the details are as capricious as that great man could possibly have invented ; but of the library of St. Mark at Venice we entertain the greatest admiration. We have already described this in the First Book when speaking of the Venetian school. Notwithstanding the difficulties that Sansovino had to encounter in respect of its site and connection with other buildings, which restricted the design in the façade, because of the height of the adjoining *Procurazie Vecchie*, and the width of the ground ; — notwithstanding all these, and the jealousy of his enemies superadded, Palladio considered the success of it to have been so great as to have made it worthy of any age.

2911. The splendid collection of books at Paris, containing 900,000 and upwards printed volumes, called the *Bibliothèque du Roi*, is, speaking architecturally, though of immense extent, little more than a warehouse for holding the books : that, however, of the abbey of St. Geneviève in the same city, though containing less than a quarter of the number just mentioned of printed volumes and 30,000 MSS., is a well-conceived and well-designed building, and particularly suited to its destination. The plan is that of a large Greek cross, which affords on the plan four large halls, connected by a central circular apartment crowned with a dome.

2912. Perhaps one of the most absurd distributions of plan for the buildings under consideration is to be seen in the Radcliffe Library at Oxford. It is circular on the plan, and hence vast loss of room is experienced ; but we do not think it necessary further to enter into its demerits, merely stating here that it was unworthy of Gibbs, who in most of his works exhibited great good sense.

## SECT. X.

## MUSEUMS.

2913. A museum is a building destined to the reception of literary or scientific curiosities, and for that of the works of learned men and artists. The term was first applied to that part of the palace at Alexandria appropriated solely to the purpose of affording an asylum for learned men ; it contained buildings and groves of considerable magnificence, and a temple wherein was a golden coffin containing the body of Alexander. Men of learning were here lodged and accommodated with large halls for literary conversations, and porticoes and shady walks, where, supplied with every necessary, they devoted themselves entirely to study. The establishment is supposed to have been founded by Ptolemy Philadelphus, who here placed his library. It was divided into colleges or companies of professors of the several sciences, and to each of such professors was allotted a suitable revenue. Museums, in the modern sense of the word, began to be established about the sixteenth century, when collections were formed by most of the learned men who studied natural history.

2914. Museums on a small scale are becoming every day more common in the principal towns of this country, and we hope the day is not distant when none will be without its collections of science, literature, and art. Where economy requires it, and the collection in each department be not too large, the whole may be properly and conveniently comprised within one building. In respect of security against fire, and quietness of the situation, the same precautions will be necessary as are indicated for libraries in the preceding section, and must always be observed.

2915. Great skill is necessary in introducing the light properly on the objects in a museum, inasmuch as the mode of throwing the light upon objects of natural history is very different from that which is required for pictures, and this, again, from what sculpture requires.

2916. Specimens illustrating natural history sculpture, vases, and the like, should, if possible, be lighted vertically ; and we have seen in subsec. 2774., where reference is made to the light introduced into the Pantheon, how very small an opening in a spherical ceiling will produce abundance of light. There are subjects, nevertheless, in all these classes, (in mineralogy for example,) for which strong side lights are essential to an advantageous exhibition of them. In such cases small recesses may be practised for the purpose. At the

*Hotel de Monnaies at Paris*, the presses which contain the collection of mineralogy form a circle which encloses a small lecture theatre, and thus become doubly serviceable. We mention this *en passant* that the student may be aware how room is to be gained when the area of a site is restricted. Picture galleries in a museum, as elsewhere by themselves, when containing large paintings, should be lighted from above. In this case the lights should be in square or polygonal tambours, whose sashes should be vertical or slightly inclined inwards, their forms following the form on the plan of the rooms. The noble pictures of Paul Veronese at the Louvre could not be seen with side lights. For small cabinet pictures side lights are well adapted to their display. Every one will recollect how miserably lighted for exhibiting the pictures is the long gallery of the Louvre; the same may be said, though not to so great an extent, of the collection of sculpture, whilst the models and other objects, paintings excepted, in the Vieux Louvre, are exhibited to perfection.

2917. Where the same museum is to contain several classes of objects the suites of rooms for the different departments should be accessible from some central one common to all: this may be circular or polygonal, as may best suit the arrangement and means; and, if possible from the site, the building should not consist of more than one story above the ground; on no account of more than two.

2918. For the objects it contains we question whether the British Museum is surpassed, as a whole, in Europe; and those of the Vatican, of the Uffizj at Florence, of Portici, and of Paris, are none of them of sufficient architectural importance to detain the reader by description; neither would they, if so described, be useful to the student as models. At Munich the Glyptotek for sculpture, and the Pinacotek for pictures, are in some respects well suited to the exhibition of the objects deposited in them, better, indeed, than is the museum at Berlin. These have all been much praised by persons of incompetent judgment as specimens of fine architecture; but we cannot recommend the study of them to any one who is desirous of acquiring a pure taste in the art, nor indeed any other works of the modern German school.

2919 In the composition of museums decoration must not be exuberant. It must be kept in the interior so far subordinate as not to interfere with the objects to be exhibited, which are the principal features of the place. With this caution we do not preclude the requisite degree of richness which the architecture itself requires. Using the shorthand of the previous chapter — , the Greek cross, connected by a dome in the centre, for the great hall of communication, is perhaps as good a form for a museum on a small scale as could be adopted: however, this is a matter which would form an admirable exercise for the student.

## SECT. XI.

### OBSERVATORIES.

2920. We had great doubts upon the admission of this section, not because of its want of importance, but because we can scarcely bring ourselves to the conviction that traversing domes for equatorial instruments and chases in a roof for fixed ones can be ever united with beauty of design. The observatory at Paris, from the designs of Perrault, is a noble building, but, we believe, is universally admitted to be very ill suited to the purposes for which it was built. Hence we shall be brief in what we have to say under this section.

2921. A regular observatory is one where instruments are fixed in the meridian, whereby, with the assistance of astronomical clocks, the right ascensions and declinations of the heavenly bodies are determined, and thus motion, time, and space are converted into measures of each other. On the observations and determinations made in such establishments they are therefore, to maritime states, of vital importance, and ought to be liberally endowed by their governments. As the subject will be better understood by a plan, we subjoin, in *fig. 1031.*, a plan and elevation of the observatory at Edinburgh. The general form of the plan, as will be therein seen, is a Greek cross, 62 feet long, terminated at its feet by projecting hexastyle porticoes, which are 28 feet in front, and surmounted by pediments. The intersecting limbs of the cross at their intersection are covered by a dome 13 feet diameter, which traverses round horizontally, and under its centre a pier of solid masonry is brought up of a conical form 6 feet in diameter at the base, and 19 feet high. This is intended for a portable astronomical circle or for an equatorial instrument for observations of the heavenly bodies made out of the meridian. In the eastern foot of the cross (*bb*) are stone piers for the reception of the transit instrument; *c* is the stone pier to which the transit clock is attached; and *d* is a stone piece on which an artificial horizon may be placed, when observations are taken by reflection: this is covered by a floor board when

Fig. 1031.

not in use, being just under the level of the floor; *aa* are the slits or chases running through the walls and roof, but closeable by means of shutters when the observation is completed. On the western side (*ee*) are chases as in the transit room; *f* a large stone pier for the reception of a mural circle; *g* the clock pier; *h* the pier for an artificial horizon as before; *i* is the conical pier above mentioned, over which the moveable dome is placed, having an opening (*l*) in the elevation for the purpose of observation; *k* is the observer's room; and *m* the front entrance.

2922. It is to be especially observed that the piers for the reception of the instruments must not be in any way connected with the walls of the building; they should stand on the firmest possible foundation, which, if at all doubtful, must be formed with concrete, and the piers should, if possible, be out of a single block of stone; but if that cannot be obtained, the beds must be kept extremely thin; partial settlement being ruinous to the nicety of the instruments as well as to the observer's business. The observation applies also to the clock piers, all vibration and settlement being injurious also to them. At the Campden Hill observatory, near Kensington, belonging to Sir James South, there is a traversing dome 30 feet diameter in the clear.

2923. A dry situation should be chosen for the site, for, except in the computing rooms, no fire heat can be allowed; and it is important that the brass whereof the instruments are made should not be corroded by the action of moisture. In large public observatories there should be the readiest access from one part to another, and rooms for a library and computers independent of the chief astronomer's room.

## SECT. XII.

## LIGHTHOUSES.

2924. It may perhaps be thought that we are touching on the province of the engineer in devoting a section to lighthouses; but we cannot forego the completion of the previous section by some few observations on lighthouses, which are the handmaids to the important results which flow from observatories, being the spots which verify the course of the navigator, and serve as precautions for his guidance when near the shores of a country.

2925. The lighthouse dates from the earliest period; and without entering into the question whether the ancient lighthouses were dedicated to the gods, or whether the towers erected for the purpose of warning the mariner were nautical colleges, where astronomy and the art of navigation were perfectly taught, we may at once proceed to state that in the earliest times they appear to have consisted of a tower of masonry, sometimes of a circular form, but usually square, and consisting of various apartments, as the establishment was greater or less, wherein was a raised altar upon which the beacon was established.

2926. Those who wish to pursue the history of the lighthouse must be referred by us to Jacob Bryant, whose theory is so pleasant that to it we must apply the old Italian saying, "*Se non è vero è ben trovato.*" We therefore leave the reader to consult our author on the subject of the purait or fire-towers. So also we shall not touch upon their perversion, nor the alleged dissoluteness and barbarity of the priests and priestesses who had the care of them, which we believe to be fables.

2927. Certain however it is that the whole of the ancient establishment of fire-towers or lighthouses at an early period common on the shores of the Mediterranean, the Archipelago, the Bosphorus, and Red Sea, have long since disappeared. Among the most celebrated of these was the Pharos of Alexandria, which has given its name in French and Italian to all lighthouses. It was accounted one of the seven wonders of the world, and, in history at least, has perpetuated the glory and name of its founder, Ptolemy Philadelphus. If Pliny may be relied on, it was the work of Sostratus, 300 years before the Christian era, and bore an inscription to the following effect: "Sostratus the Gnidian, the son of Dexiphanes, to the gods preservers, for the benefit of those who use the sea." Lucian, however, says that this inscription was craftily covered with plaster, on which the name of Ptolemy was inscribed, but that the decay of the plaster left the name of Sostratus only. The story is however improbable, and is dependent entirely on the authority of the satirist. The dimensions of this building are not satisfactorily known: some have said its height was 300 cubits, or 100 times the height of a man, which would assign to it a height of 550 feet. On its top a fire was constantly kept, which, according to Josephus, was seen at the distance of three hundred stadia, equal to about forty-two British miles, which is a reasonable account; but those who have delighted in marvellous stories have made the distance one hundred miles, and others have wonderfully gone beyond the last by assigning seven hundred miles as the distance, from which the speculum used distributed light! That this work was one of extraordinary magnificence cannot be doubted; the cost has been stated at 800 talents (300,000*l.* sterling); and there is reason to suppose that it was *quasi* the parent of all others: but all we have said must be taken with great allowance, except that we believe it was a splendid monument of the time.

2928. We have thus far extended in this case our observations, not perhaps in very strict accordance with the plan of this chapter, which relates rather to principles than history; and the only excuse we offer is, that we know not where in our work they might have been more appropriately introduced. We perhaps may not better satisfy the reader in what follows; which, from the nature of the subject, must be more instructive from what has been actually executed than from the general principles upon which the construction of a lighthouse depends.

2929. The most architectural of modern lighthouses is that of Corduan on the coast of France, which stands on a large rock, or rather on a low island, about three miles from land, at the entrance of the river Garonne. Like that of Alexandria, this lighthouse seems to have been intended for the commemoration of an æra in the history of France from the eminent utility of the building and the magnificence of its structure. Founded about the year 1584, in the reign of Henry II. king of France, it was carried on under the reigns of three successive monarchs, arriving at its completion in 1610, in the reign of Henry IV. It stands upon a platform of solid masonry, and is surrounded by a parapet about 145 feet in diameter, which is equal to the height. The lightkeepers' apartments and store rooms are not in the main tower, but form a detached range of buildings on the great platform, the interior of the tower itself being finished in a style of magnificence too splendid for the use of common persons. Over the fuel cellar, which is formed in the solid masonry of the platform, is the great hall, 22 feet square, 20 feet high, with an arched

ceiling. On this floor are two wardrobes and other conveniences. Above the last-mentioned room is the king's room, 21 feet square and 20 high, with an elliptical ceiling. There are on this floor a vestibule, two wardrobes, and other conveniences. On the third floor is placed the chapel, for a priest who occasionally says mass is attached to the establishment, and this is 21 feet in diameter, domed, and 40 feet high, and lighted by eight windows. There is an eye in the dome through which is seen the ornamental roof of the room above, and that is 14 feet diameter and 27 feet high. This is used by the lightkeepers as a watch room. Over it rises an apartment, which is immediately under the light room, used for holding sufficient fuel for one night's consumption, and capable itself of being converted into a place for the exhibition of a light in case of repairs being required to any extent in the main light room, which, as we have said, is immediately over it, and is surrounded by a balcony and circular stone parapet. The height from the floor to the top of the cupola of the original lantern or light room was 17 feet, and being unglazed, the smoke was carried out on either side in the direction of the wind. The roof, moreover, formed a kind of chimney in the form of a spire, terminating with a ball. The height of the light room, which was entirely of stone, was 31 feet from the light room floor to the ball on the top of the spire. The fuel first used for the light was oak, after which pit coal was introduced; but in modern times lamps and reflectors have succeeded the last, and the light is now seen at a proper distance.

2930. In England the student may turn to the Eddystone lighthouse, by the celebrated Smeaton, not only as an object of great beauty, but of that soundness of construction, which is the most essential requisite in works of this kind. The general form is seen in fig. 1032. This is a fine illustration of fitness producing beauty. The resistance it affords against the waves arises from the beautiful curved line which leads them up it instead of being broken against it. Indeed, in stormy weather, the waves actually roll up the side, and fall in a contrary curve over the top of the lighthouse. The beds of the masonry are so laid and dovetailed and joggled into the rock itself as to become a part of it. The foundation stone of it was laid on the 12th of June, 1757, and it was first lighted on the 16th of October, 1759. A narrative of the work was published by Mr. Smeaton, to which for detail the reader is referred. The two lower stories are used as store rooms; the next above serves for the kitchen, above which is the bedroom, over which is the light room.

2931. Thus, we see, there is no reason why lighthouses should not be beautifully formed structures, instead of absurd misshapen masses of masonry, as they generally are. The attempt to make them resemble columns is intolerable; they should possess, according to the different situations, a character peculiar to themselves: hence the application of a column for the purpose is the worst of abuses. The North Foreland lighthouse, whose plan is polygonal, would be a good example had the details been properly attended to in the design. We do not here touch upon the mode of lighting, which has of late years occupied much attention, having considered the duty of the architect performed when he has provided a beautiful, lasting, and secure fabric for the reception of the lights.

Fig. 1032.

## SECT. XIII.

## ABATTOIRS OR PUBLIC SLAUGHTER-HOUSES.

2932. It may be thought unnecessary to assign a section in this work to the consideration of a species of building unfortunately unknown to this country, in which its non-employment is truly a reproach. The improvements still in progress however in the metropolis justify, we hope, the expectation that the paltry interests of a particular class, and the disgraceful opposition of the corporation of the city of London, will not much longer prevail to prevent the removal of Smithfield market, and the establishment of public slaughter-houses or abattoirs round the different outskirts of the metropolis. It is the duty of the legislature

to interfere and stop the danger and unwholesomeness of the present practice, and not to leave it to individuals to improve the comforts and security of London and its suburbs. The cemeteries established by companies have done much: we hope to see the day when the subject in question will be forced on the government, without respect to the corporation tolls of the market at Smithfield.

2933. The accidents arising from overdriving cattle through the narrow streets of Paris, and the infectious effluvia from the slaughter-houses often causing contagious maladies in their neighbourhood, induced the French government, in 1811, to execute a project which had been entertained for nearly a century previously, that of removing all the slaughter-houses from the heart of their capital. The result of this determination has been, not only the prevention of all cause of complaint of the former inconveniences, but has produced a set of buildings bearing a character of grandeur and magnificence proportionate to their destination. It was a worthy exercise of the power of the government; it has obviated the disgraceful sights almost every day witnessed in London, sights tending to deprive the lower classes of humanity, and to render them ferocious, to corrupt the mind, to offend the eye, and to injure the public health. Without strictly adhering to the term *abattoir*, which would more properly signify a slaughter-house where the cattle are slaughtered, we mean by our proposition, not only the place for killing the cattle, but an establishment where, after they are killed, under the inspection of proper officers, the skins are arranged for sale, as well as the tallow obtained from the fat, before these are distributed to the respective trades.

2934. Political economists have doubted whether an individual ought to be restricted in the exercise of his industry wherever he may think it most conducive to his interest; we are however inclined to apply to the principle the maxim of the lawyers, "*sic utere tuo ut alienum non lædas*," and think that disagreeable and unwholesome establishments should be removed from all large cities. The experiment however, at all events, has been most successfully made in Paris, where butchers are no longer allowed to kill their cattle, except in the public *abattoirs*. For the purpose five open airy spots have been selected in the outskirts of the city, corresponding in size to the demand of those parts of the town to which they are correspondent. Those of Menilmontant and of Montmartre are the most considerable and extensive; but the rest are constructed on similar plans, in which there is no difference except in the number and extent of the buildings. We shall therefore describe generally the first named, that of Menilmontant.

2935. The slaughter-house of Menilmontant at Paris is situated on a declivity, which contributes to its good drainage, and the consequent salubrity of the establishment. It stands on a site about 700 feet by about 620 feet, being insulated between four streets. Through an iron railing, about 108 feet in extent, flanked by two lodges, or *pavillons*, in which are accommodated the officers of the establishment and their *bureaux*, is the principal entrance of the edifice. On entering from this a large square space presents itself, from the centre whereof may be seen the whole of the buildings, twenty-three in number, composing the *abattoir*. This court is about 315 feet broad, and on its great sides about 475 feet long, and on its right and left are four double buildings, separated by a road which traverses the whole ground parallel to the principal façade. These are the slaughter-houses, each whereof is about 200 feet long by 136 feet in breadth, and they are separated by a paved court, in the direction of their length, so inclined as to carry off the filth, such court dividing them into two piles of building, each of which contains eight slaughter-houses for the particular use of the butchers. Each slaughter-house is lighted and ventilated from openings in the front walls. Above them are attics for drying the skins and depositing the tallow, and to keep them cool the flat roofs project very considerably. Behind the slaughter-houses, and parallel to them, are two sheepfolds, and at their extremities two stables, each of which contains lofts for the hay, and on each side of the court complete the two masses of building which compose the design. At the end of the court is a convenient watering place, and two folds for the first distribution of the cattle; and also two insulated buildings for melting the tallow. These are intersected by a broad corridor, giving access to four separate melting-houses, with vaulted cellars, which serve as coolers. Beyond these, parallel to the enclosing wall, are two long buildings, divided into many warehouses on the ground and first floor, and standing on cellars, in which the undressed leather is kept, the upper floor being destined for the reception of calves' and sheep skins. The last point to be noticed is a large double reservoir of water, of masonry, carried on two series of vaults, which serve as stands for carriages. A steam-engine between the two basins pumps the water into the reservoir. The basins are about 323 feet in length. Happe was the architect; and the cost was something above 120,000*l*. The rent which some years ago the five establishments yielded to the city was about 12,000*l*. per annum.

2936. The description we have given shows the general distribution of the buildings, which are the subject of the section. Although general, we apprehend that, with the particular information of which in every case the architect must possess himself, enough has been said on the subject.

SECT. XIV.

EXCHANGES.

2937. An exchange is a place of meeting and resort for the merchants of a city to transact the affairs relating to their trading. We are not aware that the ancients had any edifices exactly in their destination resembling the modern exchange, as used by us in these days; there is, indeed, every reason to believe that the ancient basilica served at the same time for the accommodation of the officers of the law and for the assembling of the merchants.

2938. All modern cities with any pretension to commerce have some place appropriated to the reception of the merchant, to which at a certain hour he resorts. Sometimes we find it a place surrounded with porticoes and planted with trees. Often it is a building, including several porticoes on the ground floor, surrounded by offices for the bankers and money-changers, which latter use has given among us the name of exchange to the building.

2939. The Exchange at Amsterdam seems for a long time to have prevailed as the model for all others. It was commenced in 1608, and finished in 1613, and its architect was Cornelis Dankers de Ry. It is about 271 feet long, and about 152 feet wide. The whole edifice is supported on three large arches, under which flow as many canals. On the ground floor is a portico surrounding a court, above which are halls supported on forty-six piers. The divisions which they form are numbered and assigned each to a particular nation or class of merchants. In the court, and within the enclosure, is the place of meeting for mercantile affairs. At the top is another large hall, and a warehouse for various kinds of merchandise.

2940. The exchange is, perhaps, next in importance to the cathedral of the city, and should be commensurate in appearance and accommodation with its wealth and consequence; it should, moreover, if possible, be placed in the most central part. Such was Sir Christopher Wren's idea in forming the plan of London after the conflagration. He considered the forum of the ancients to be the true model upon which a modern exchange might be engrafted, and we think he was correct. Any edifice which in appearance resembles an ancient temple is unfit in character, and shows puerility and poverty of imagination in the designer. Porticoes are the principal features of such a building, and the variety in which they may be used for the purpose is infinite, and will afford ample scope for the artist's talent.

2941. No offices or shops, as about to be constructed in the new Royal Exchange, for the purpose of obtaining rent, should be connected with the fabric, save only as in Paris, for example, a *Tribunal de Commerce* with its accessories, an establishment much wanted in England; and perhaps in addition to this, in a maritime country like ours, a large hall and offices for the transaction of business relating to the shipping interest.

2942. In London and other places it has been usual to leave the court of resort open to the heavens; an absurd practice, which, we suppose, because it was, so before, has been re-adopted in the exchange about to be rebuilt in this city. The French are wiser, and though the weather is, generally speaking, much finer in France than it is here, they build their exchange with a roof, for the comfort of those that use it. If, however, our merchants prefer exposure to the inclemency of the seasons, it is not our business to complain of the fancy.

2943. As we consider the Bourse at Paris an admirable model, both in distribution and design, we shall briefly here describe it. The edifice in question was begun in 1808, under the designs of Brongniart, and completed by Labarre at a much protracted period. The general form on the plan is a parallelogram of 212 feet by 126 feet. It is surrounded by an unbroken peristyle of sixty-six Corinthian columns, supporting an entablature and attic. The peristyle forms a covered gallery, to which the ascent is by a flight of steps extending the whole width of the western front. The intercolumniations on the walls are filled in with two tiers, one above the other, of arched windows, separated by a Doric entablature, and surmounted by a decorated frieze. The roof is formed entirely of iron and copper. In the centre of the parallelogram is the *Salle de la Bourse*, or great hall, 116 feet long and 76 feet broad, wherein the merchants and brokers assemble. The Doric order is that used with arcades round the sides, and between the arcades are inscribed the names of the principal mercantile cities in the world. The ceiling is formed by a cove, and in the centre a large skylight serves for lighting the great hall just described. It is rich in sculpture, and decorated with monochrome paintings, to imitate bassi relievi, sixteen in the whole, that is, five on each long and three on each short side. They are all allegorical. The hall conveniently contains 2000 persons. At its eastern end is a circular space railed off for the convenience of the *agens de change*: these only are admitted within it, and to it there is a communication from their hall of business. On the right are rooms for the committee

and syndicate of the *agens de change*, for the *courtiers de commerce*, and a hall of meeting for the latter. On the left is an ample staircase leading to the gallery, supported by Doric columns, and to the hall of the Tribunal de Commerce, with its several apartments and waiting rooms. From the gallery, as on the ground floor, a corridor extends round the Salle, communicating with the Chamber of Commerce, the Court of Bankruptcy, and other public offices. The cost of this very elegant and splendid building was about 326,000*l.*; but the merchants and city of London disgrace themselves by allowing 150,000*l.* for a similar purpose here; and even for this sum they cut up their building into little slices, to reimburse themselves by rents for the miserable outlay. So much for the spirit and liberality of the British merchant!

## SECT. XV.

### CUSTOM-HOUSES.

2944. It is almost unnecessary to inform our readers that a custom-house is an establishment for receiving the duties, or, as they are called, customs levied on merchandise imported into a country, as well as of regulating the bounty or drawback on goods exported. According, therefore, to the importance and wealth of a city, the building to receive it is of considerable consequence. The first point that immediately presents itself is, that it should be provided with spacious warehouses for holding the merchandise which arrives, and in which it is, as it were, impounded till the duties are paid; and next, that there must be provided ample accommodation for the officers who are to supervise the levying of the imposts. Now, these being the data, it is manifest that there can be no building so subject to modification in every respect as a custom-house, and that that which might be well suited to a small town or city, looking to its trade, would be ridiculous either in excess or smallness in another. Yet there are general principles which should guide the student in designing the smallest as well as the largest establishment of this sort, and these are contained in the two maxims, of ample capaciousness for the merchandise to be received into the warehouses, and a panoptical view, on the part of the proper officers, of that which passes in the establishment. Without these requisites, a custom-house is an ill-planned building; but it is not to be supposed that such an observation can apply to an establishment of this nature in a metropolis like London, the subdivisions and details of whose commerce have found as yet all the delegations of the customs in the various docks and sufferance wharfs still even too small for the commerce of the country, and have induced the government to extend the collection of the dues beyond the central establishment. We must, however, return to the custom-house calculated for a port of ordinary size, and not that of a metropolis like London, though presently we must refer to what on that has been thought necessary for our guidance in smaller matters. Security against fire must be strictly attended to. The warehouses and covered places for examining and stowing the goods should therefore be arched in brick or stone, and should, moreover, be as much as possible on the ground floor. The offices for the public and heads of the establishment may be over them on the first floor. Both of these are, of course, to be regulated in size by the extent of trade in the place. The general character should be that of simplicity; decoration is unsuited, and should be very sparingly employed. The species of composition most suitable seems to be pointed out in arcades and arched openings. The site should be as near as may be to the river or port, so that the merchandise may be landed and housed with as little labour as possible.

2945. The following is a general view of the apartments and offices of the London Custom House. The long room, which is the principal public room for the entries &c., is 190 feet long and 66 wide. This, as well as the rooms next enumerated, are on the first or principal floor, viz. a pay office for duties, treasury, bench officers or commissioners' rooms, secretary's room, rooms for the inspector general, surveyor of shipping, registrar of shipping, surveyor of acts of navigation, strong rooms, comptrollers, outward and inward, surveyor of works; Trinity light office, bond office, board room, chairman's room, committee room and plantation clerk's office. On the ground floor are the following offices: for minute clerks, clerk of papers, petitions, messengers, landing surveyors, wood farm office, tide waiters, tide surveyors, inspectors of river, gaugers, landing waiters, coast waiters, coast office long room, coast bond office, coffee office, housekeeper, searchers, merchants and brokers' rooms, comptrolling searchers, appointers of the weighers and office for the plantation department. Besides these apartments there are warehouses for the merchandise.

2946. The above long list will give a notion of what would be wanted on a smaller scale; but on such matters the special instructions on each case must be the guide to the architect in making his design. Many of the above offices would, of course, be unnecessary

in a small port, neither would the dimensions be so large as in the example quoted. The staircases, corridors, and halls must be spacious in all cases, the building being one for the service of the public.

## SECT. XVI.

## THEATRES.

2947. A taste for dramatic representations prevailed at a very early period among the people of antiquity, and this was not diminished by the introduction of Christianity, even when the temples were deserted and paganism seemed extinct. The destruction of these, however, was its concluding triumph. It would be a difficult matter to fix the precise date of the abolition of the pagan theatre, but it seems likely to have resulted rather from the falling into decay of the old theatres than from a disinclination on the part of the people to the pleasure they received at them. It is not, however, the object of this section to trace the history of the theatre; though we think it right to say a few more words on the subject. With the revival of the arts, the taste for scenic representations appeared with the literature on which they are dependent. In Italy we find, therefore, the drama at this period represented in very large enclosures, such as the amphitheatre constructed by Bramante in the large court of the Vatican, whence the taste soon spread over all the nations of Europe.

2948. The pleasure which flowed from this renewal of an ancient art was at first confined to few, and those were either men of learning or select societies, who bore the expenses, and again raised in the country a renewal of a theatre much resembling those of the ancients as respected the form and disposition. To prove this, we need only cite the example of the celebrated theatre at Vicenza, built by Palladio in 1583, and designed in imitation of the ancient theatres. Its form is a semi-ellipsis, whose transverse axis is parallel with the scene, encompassed with fourteen ranges of steps for the spectators. The greater diameter of this ellipse is  $97\frac{1}{2}$  feet, and the lesser, as far as the stage, about  $57\frac{1}{2}$  feet. At the summit is a corridor of the Corinthian order, which, from the want of ground, could not be detached all round from the external wall. The nine central and the three external intercolumniations, therefore, where the columns touch the external wall, are filled with niches and statues. The stage is designed with two tiers of Corinthian columns surmounted with an appropriate attic. In the front of the stage are three openings through which three avenues of magnificent buildings appear, and at the end of each is a triumphal arch. All these are executed in alto relievo, but are foreshortened and diminished perspective. A full account of this building, which is well worth the student's attention, is given in *L'Origine dell' Accademia Olimpica*, &c. *Opera di Ottavio Bertotti Scamozzi*. Vicenza, 1690. For dramatic representations this theatre is no longer used, and at present it is only recognised as a monument of the extraordinary skill of the architect, and a memorial of the dramatic buildings of its period. The theatre at Parma, built by Aleotti, is another building belonging to the same class, and preserved, like the last-mentioned, as a curiosity.

2949. When, however, the taste for scenic amusements began to spread, the sovereign princes, who alone could support the expense of such establishments, began to make them a necessary part of their palaces; and the theatre, no longer a public and essential building, became what it now is, not an edifice for the reception and accommodation of the whole population of a city at certain periods, but a place which served for the habitual amusement of those who could afford it. The drama again revived, and its history is an index to the edifices that rose for its representation. Becoming thus necessary for the amusement of the better classes of society, the establishment of theatres was undertaken by individuals in almost every city, and competition was the natural consequence. Then began the division of the theatre into different parts, the entry to which was marked by different prices, and the separation of the common people from those of rank and fortune.

2950. Italy does not contain so many theatres, nor of such consequence, as might be predicated from the taste of its inhabitants. Among the earliest of consequence was that built at Bologna in 1763 by Antonio Galli Bibiena, (not to mention that built at Verona under the direction of the celebrated Scipio Maffei by Francesco Galli Bibiena,) with a noble portico in front and salons in the angles, possessing moreover great merit in its interior distribution. In the Italian theatres there is almost invariably a certain feeling of grandeur and unity about the interior little to be expected from the exterior, which in no way leads the spectator to the suspicion of a fine *Salle de Spectacle* behind it.

2951. France has the credit of having erected the first modern theatre that can be denominated an example in this species of monumental architecture. That to which we allude is the theatre at Bordeaux, which is 325 feet in length, and half that measure in width. It is surrounded by arcades, whose piers are decorated with pilasters of the Corinthian order, running up the whole height through the ground and one-pair stories. Set back, an attic

is raised, which conceals the roof, wherein the necessary accommodations which a theatre requires are disposed. Whether we consider the exterior or interior of this edifice, everything is grand; the accessories are worthy of the whole, and the richness of the interior decoration is only equalled by the fine forms whereon the decorations are used. The ingress and egress are admirable; and a splendid concert-room and magnificent staircases complete the destination, to which it is so suited, as to afford the finest model of a theatre to which we can refer the student. The plans, &c. of this work were published by the architect, under the title of *Salle de Spectacle de Bourdeaux*, atlas folio, Paris, 1782. Paris but followed Bourdeaux in improving its theatres, and latterly the metropolis of England followed in the wake.

2952. The principal points for the consideration of the architect in the composition of a theatre, may be classed under the heads of utility, suitability for the purpose, and taste in combining them. Under the first head must be placed the accomplishment of two main objects, those of seeing and hearing what passes on the stage. These, indeed, are intimately connected with each other, and are entirely dependent on the form adopted for the plan of the interior, that is, the general form given to the boxes which surround the part before the curtain. We are not aware of any plan which, in this respect, is not based on a quadrangular, elliptical, or circular form.

2953. The quadrangular form, besides its want of beauty, is not well adapted for fulfilling the objects with which we set out. In this, the greater number of spectators or audience who occupy the side boxes, are so inconveniently placed, that, to observe what is going on, their heads must be turned sidewise, and they are hence in a false position for the object. The actor being generally the point to which all eyes are directed, the spectator close to the proscenium will look at him in a right direction; but as the spectator removes to the extremity of the side, it is manifest that the angle in which the head must be turned becomes sharper, and the position is then painful. Besides this objection, the form is known to be unfavourable to hearing or to the propagation of sound.

2954. The truncated oval is in some measure subject to the same inconveniences on the sides as the last-mentioned figure. It removes also a large portion of the spectators to a considerable distance from the centre of the scene, besides which, in the boxes near the proscenium their seats tend in opposite directions to the actor. It has been to remedy these faults that the form of the horseshoe has been adopted, which is a sort of mean between the quadrangular and oval forms: and where the plot of ground is much longer than it is wide, it is a suitable figure, and one which affords the opportunity of increasing the number of boxes.

2955. When, however, the circumstances concur in allowing it, the adoption of the semicircular plan is doubtless the best. It is a figure which allows each spectator to be at an equal distance from the scene, that also by which the spectators in adjoining boxes less interfere with one another, that which affords the means of all seeing equally well, that in which the sound is most equally distributed, and that whose uniformity and simplicity seems to engender the best decoration. The semi-elliptic, with the transverse axis parallel to the proscenium, has interior advantages in some respects over the semicircle; but it induces great difficulty in connecting the proscenium itself with the auditory part of the house, and, by increasing the width of the proscenium, increases the difficulty of framing the roof conveniently for the painting rooms, and securely as respects the walls.

2956. Upon the destruction by fire of Drury Lane Theatre, a pamphlet appeared, entitled "Observations on the Principles of a Design for a Theatre," by Benjamin Wyatt, London, 8vo. 1811. These observations are so well worth the notice of the student that we shall close this section by giving the substance of them. The heads for consideration, says the author, are —

2957. *First.* The size or capacity of the theatre, as governed by the width of the proscenium or stage opening; and by the pecuniary return to be made to those whose property may be embarked in the concern. *Second.* The form or shape of the theatre, as connected with the primary objects of sound and vision. *Third.* The facility of ingress and egress, as materially affecting the convenience of those who go to every part of the house respectively, as well as their lives, in cases of sudden accident or alarm. *Fourth.* Decorum amongst the several orders and classes of the visitants to the theatre, as essential to the accommodation of the more respectable part of those visitants, and consequently of great importance to the interests of the theatre. *Fifth.* Security against fire, as well with relation to the expense of insurance as with relation to the lives of individuals going to the theatre.

2958. The size or capacity will necessarily depend very much on the width of the proscenium or stage opening, inasmuch as it is from the extremities of that opening that the form of the theatre must spring. The annexed is a statement of the width of proscenium at the theatres named: —

Argentino, at Rome	-	-	-	-	-	36 feet.
Covent Garden	-	-	-	-	-	38 feet.

Théâtre Italien, Paris (burnt)	-	-	38 feet.
Turin	-	-	39 feet.
Bourdeaux	-	-	39 feet.
Parma	-	-	40 feet.
Milan	-	-	40 feet.
San Benedetto, at Venice	-	-	40 feet.
Théâtre François, at Paris	-	-	40 feet.
Drury Lane	-	-	40 feet 6 inches.

A width beyond 40 feet seems to be considered by the performers as inconvenient from the space they would have to pass over in the business of the drama. A greater width, indeed, than that stated prevents the easy and secure working of the scenes, for the machinery is increased in magnitude and weight as the height and breadth of the scenes increase. In mere *spectacle* and scenic grouping a reduction in the width of the proscenium reduces the number of extra performers, or supernumeraries as they are called, which become necessary for filling the stage. Again, every additional foot given to the stage opening increases the quantity of canvass used in the scenes, as well as the framing whereon they are fixed.

In the *Edinburgh New Philosophical Journal*, vol. xxvii., there are, by Mr. J. S. Russell, some elementary considerations of certain principles in the construction of buildings designed to accommodate spectators and auditors, well worth the architect's notice. In every large room, says the writer, a perfectly good seat is one in which, without uneasy elevation of the head or eye, without straining or stretching, we can calmly and quietly take any easy position, or variety of positions, which we may be disposed to assume, and yet may in all of them see and hear the speaker with equal clearness and repose, so as to give him patient and undisturbed attention. The object, then, is to ascertain in what manner the interior of a building for public speaking should be formed, so that throughout the whole range which the voice of a man is capable of filling, each individual should see and hear without interruption from any of the rest of the audience, with equal comfort in an easy posture,

Fig. 1033.

and as clearly as if no other individual auditor or spectator were present. (See *figs.* 1033. and 1034.) The position of the seats is first investigated. In the usual variety of station

Fig. 1034.

and of position, it appears from experiments that the range required for the purpose is more than a foot and less than 18 inches, so that these may be taken as the limits; that is, over the head of the person before you there must be a clear range of 12 or 18 inches, through which the head may be moved upwards or downwards without interruption. In other words, that a straight line drawn from the speaker's head over that of the anterior spectator shall intercept the straight line which forms the back of the seat of the posterior observer, so as to cut off a height of 12 or 18 inches, within which the head of the spectator shall at

times be comprehended while sitting in a comfortable position. Thus let *S* (fig. 1033.) be the speaker and *XYZ* be three successive ascents; then the line *SX* must fall below *SY*, so as to leave the space  $Yx = 18 \text{ inches} = Zy$ .

2959. Applying this formula to every individual place in the room or building, we shall have the form required to satisfy the auditors. Let  $2\frac{1}{2}$  feet be assumed as a constant representing the distance of one spectator behind another, measured horizontally; and  $1\frac{1}{4}$  feet as the clear space, measured on the vertical line, for the mean range of comfortable vision for each. If the level of the floor, that is, of the lowest seats, be already determined, the form of the interior accommodation may be thus described. *AY* (fig. 1034.), the height of the speaker, *YX* the level floor. From *Ay* take  $Yy = 4 \text{ feet}$ . Draw *yx* parallel to *YX*. Take *Ay* to *yx* as  $1\frac{1}{4}$  to  $2\frac{1}{2}$ , that is, as *h*, the range of position of the spectator, to *d*, the distance between the seats. Take horizontal distances 1, 2, 3, 4, &c. =  $2\frac{1}{2}$  feet, prolong *Ax* to *x'*, then the height  $x' = l = 1\frac{1}{4}$  feet. Join *Al* and prolong it to *x''*, and take a distance  $x'' = m = 1\frac{1}{4}$  feet. Through *m* draw *Am*, and prolong it to *x'''*, and take  $x''' = n = 1\frac{1}{4}$  feet. Continue the process in the same manner to *p, q, r, s, t, &c.*, and the points will be found of the successive places which the heads of the auditors should occupy.

2960. But it is not only in receding that the back seats must rise; those too far forward may be also unpleasant. They are too low; they also should be raised: but this must be done so as not to interrupt those who are behind. It may be accomplished in a similar way; for, as formerly set off, 1, 2, 3, 4, 5, 6, &c. =  $2\frac{1}{2}$  feet (fig. 1035.), 1 is the first anterior point. Join *Al*, and let it cut the vertical line through 2 in *x'*, the portion downwards  $x' = l = 1\frac{1}{4}$  feet; then *l* is the point found. Join *Al*, make  $x'' = k = 1\frac{1}{4}$  feet; join *Ak* and  $x''' = i = 1\frac{1}{4}$  feet; and so on. *g, h, i, k, l*, are the places found which the heads of the spectators should occupy, and show the elevation to be given to the seats successively.

Fig. 1035.

2961. If the simple process described be accurately performed, the points which indicate the places of the spectators will lie in the branches of a very beautiful curve, which may be termed the *iseidomal* or the *isacoustic curve*, that is, *one of equal seeing or hearing*: it will be of the form in fig. 1036. *A* being the place of the speaker, and the heads of the spec-

Fig. 1036.

tators being placed on the line *Amn*, continued as far as the voice will reach, *XAX* being the axis of the curve, and *YY* its parameter. This curve has two branches on opposite sides of *A*, showing that if the building extend behind the speaker, or if the spectacle be visible or the sound audible on every side, the same may be continued all round. By means of this curve, the position of seats in a theatre may be satisfactorily determined.

2962. For any great assemblage, where it is desirable that one individual or group of individuals should be seen or heard, an amphitheatre of this form might be constructed from the surface of revolution generated by moving the curve round its axis, which would perfectly accommodate 10,000 individuals.

2963. According to the arrangement of London audiences, Mr. Wyatt calculates that a theatre consisting of three fourths of a circle on the plan, with a stage opening of 35 feet, will contain

78 boxes, in four tiers, and holding	-	-	1004
4 boxes of larger size, on each side next the stage	-	-	188
A pit, capable of containing	-	-	911
A two-shilling gallery	-	-	482
A one-shilling gallery	-	-	284

2869 persons, exclusive of four boxes in the proscenium, and fourteen in the basement of the theatre, immediately under the dress boxes.

2964. We have already given some general hints relative to the form; we shall here add the author's view of this matter; and thereon he very properly says that, with reference to distinct sound, the safest method is to adopt a form known to be most capable of conveying sound with facility, to construct that form of materials that are conductors of sound, and to avoid all breaks and projections on the surface of that form, because they obstruct and impede the progress of the sound. It is well known that a circular enclosure without breaks possesses the power of conveying sounds with facility, and that wood is an admirable conducting material for the purpose. Count Algarotti, in his treatise on the Opera, says, daily experience teaches us that in a box whose walls are naked, the singer's voice is reverberated in a particular manner; it sounds crude and harsh, and by no means flattering to the ear; the accents are quite lost if the box be hung with tapestry; whereas they are reflected full, sonorous, and agreeable to the ear when the boxes are only boarded, which is an obvious proof, and confirmed by experience, that the best lining for the interior part of a theatre is wood.

2965. Whatever be the form of the theatre, it ought in every part to be limited in extent to such distance as the voice will distinctly reach; and the nearer that figure conforms to the proportions which the natural voice is heard in each direction, the more equally will the sound be heard in every part of the theatre. The experiments tried by Mr. Wyatt proved that the reach of the voice when moderately exerted was in the proportion of about two ninths further in a direct front line than laterally; and that being distinctly audible on each side of the speaker at a distance of seventy-five feet, it will be as plainly heard at a distance of ninety-two feet in front of him, declining in strength behind him so as not to be clearly heard at much more than thirty feet. "According," says Mr. Wyatt, "to these data, it would appear that the geometrical figure, which comes the nearest to the extreme limits of the natural expansion of the voice, is a semicircle of 75 feet radius, or 150 feet in diameter, continued on each side to the extent of 17 feet, or in the proportion of about two ninths of its lateral expansion (*fig.* 1037.) beyond the limits of the semicircle, and then converging suddenly until the two lines meet at C, behind the back of the speaker." But though the voice may be heard at these distances, it does not follow that a theatre of this extent should be erected; indeed, it would be absurd to do so, for the actor varies his place almost every moment; and as he removes from the centre, from which it has been assumed he is speaking, he would become inaudible to some parts of the audience as he receded from it. It is evident, therefore, in planning a theatre, the radius or semi-diameter must be so reduced as to bring the extreme distance at which he may in any case be placed within the space of 75 feet, that is, that when the speaker is placed at the extremity of either side of the stage, his voice may be heard by those seated on the opposite side of the house. In the diagram, the widest part of the theatre inscribed in the larger figure is 58 feet upon the level of the dress boxes; and allowing 9 feet 6 inches for the depth of the boxes on that floor, by means of a projection of 18 inches more than the boxes above, there will be 67 feet 6 inches between the extreme part of the stage on one side and the back wall of the boxes on the opposite side: but as the speaker is in no case placed at either extremity of the stage, and even if so situated, the distance between him and the opposite side of the house would be within 8 feet of the reach of his voice in its lateral direction, and 25 feet within its limits in a direct line; it hence appears that the circular is preferable to any other form; and if we fix a limit for the diameter of that form, we are in possession of the rules which limit the length of the theatre, or the distance from the front line of the stage to the boxes immediately in front of that line. Taking 75 feet for the distance at which the voice can be heard laterally, as the space between the front line of the stage and its immediately opposite boxes may occasionally be in the lateral direction of the voice, the greatest distance from the front wall of the stage to the back wall of the boxes opposite the stage should not exceed 75 feet, the limit of the voice in its lateral direction, because of the turns of head which he must often make for the business of the scene, when that which was opposite might become lateral; and thus those persons sitting in the opposite boxes would be  $92 - 75$  feet = 17 feet beyond the reach of his voice.

Fig. 1037.

2966. The use of a semicircle without modification would, however, involve the extension of the stage opening to an inconvenient width; and Mr. Wyatt very properly considers that the whole area of a theatre should contain little more than one third of the space over

which the voice can reach ; "the one," he says, "being (independently of the space behind the back of the speaker) a superficies of 11,385 feet, and the other of 4003." This, he thinks, will compensate for the absorption of sound consequent on the number of the audience, the woollen garments they wear, and the state of the atmosphere, and would ensure a good hearing in every part of the house.

2967. According to the author's statement, he recommends that the distance from the front of the stage to the back wall of the boxes immediately opposite should be about 54 feet ; in the old Drury Lane it was 74 feet, and in the old Covent Garden Theatre, built about 1730, it was 54 feet 6 inches. In the Opera House, built by Vanbrugh, it was 66 feet. At Milan it is 78 feet. At the old San Carlos, at Naples, 73 feet ; and at Bologna, 74 feet. The distance in the present Covent Garden Theatre is 69 feet 8 inches, or nearly 16 feet more than it ought to have been. How, then, can people wonder at not seeing and hearing in such theatres, where the cupidity of the projectors has overstepped the mark, and very much contributed to the ruin of the drama ?

2968. In an opera house the band as it were sustains the voice, and the *spectacle* of the ballet is more addressed to the eye than to the understanding ; but even in that the theatre is universally too large for the pleasure of those who appreciate properly what is transacted in the scene. It is satisfactory to know that the theatre which we in our introductory remarks selected as a model should coincide in the main points here in question with Mr. Wyatt's project. We are not certain whether he has visited it, but are certain that if he has he would not change his opinion.

2969. In respect of vision in a theatre, there can be no question that the semicircle gives the best chance for the whole of the audience ; but the objections to it are, that it requires that either the stage opening should be of inconvenient width or that the size of the house should be too small. It is therefore, without modification, inadmissible. It is on this account that the ellipse, the horseshoe, and other flat-sided forms, have in later theatres been adopted, though it is manifest that a large proportion of the audience, says our author, "must be placed with their backs inclining towards the scene, and that in *all* of them (if the house be not of extremely *small* dimensions) the front boxes must be at a great distance from the stage ; for in proportion as the sides shall approximate each other the front must recede, provided the circumference be not varied." The summing up of the question on this head is thus given by Mr. Wyatt : "There is no object connected with the formation of a theatre which, in all its bearings, is of more importance than that the part of the house which faces the scene should be within a moderate distance from the stage. Unless that be the case, it is obvious that a very large proportion of the spectators must be excluded from a clear and distinct view of that play of the features which constitutes the principal merit of the actor in many of the most interesting scenes." Mr. Wyatt does not believe that the height of the ceiling injures or affects the sound of the voice in the lower parts of the theatre, and observes that it must in every theatre "be much too high to act as a reverberator or sounding board to the lower parts of the house." But we do not agree with him on this point, and think we could refer him to more than one theatre in the metropolis which is defective in the conveyance of the sound from this cause alone. Besides this, we do not feel quite certain that the diagonal line drawn from the actor to the upper tier of boxes should not be the regulating distance, instead of the horizontal one which has been mentioned above.

2970. Ingress and egress should be provided on each side of the house, so that whatever doors, passages, and staircases are placed on one side, there must be corresponding ones on the other. The spectators are thus divided, and pressure avoided. Angles should as much as possible be avoided, as well as steps in passages, for which no excuse can be offered. Doorways ought not to be less than six feet wide, nor should staircases be of less dimensions. In large staircases, which consist of a centre and two side flights, the central one should be equal in width to the side flights added together. In calculating the size, regard should in some measure be had to the number of persons which the part they serve will contain.

2971. It is only in an English theatre that the public have to complain of the admission of the most unfortunate members of the community, and of their subjection to scenes of great indecency. Nothing of this sort occurs on the Continent, whilst here the proprietors of theatres allow the admission of such persons at a reduced rate of payment if they take an admission for the season. As, in this country, it is impossible to exclude any particular class of persons, it would be well so to contrive the access to the dress circle of boxes that it may be arrived at without passing near the saloons, which are generally the resort of the class of people alluded to.

2972. With the exception of the dressings and interior ornaments of the building, and those parts of the stage and machinery which must be made of wood, it would be possible, though perhaps somewhat inconvenient, to erect a theatre, though not absolutely fire-proof, yet very secure against fire. This is, however, a subject not to be treated here ; but we ought not to omit that the supply of water from large reservoirs provided in the upper parts of the

building, is a precaution which should never be omitted. Pipes may be laid on from them to those parts, such as the carpenters' room, scene room, and painting room, where fires would be most likely to break out, and where, if they did break out, they would be likely to be most dangerous.

## SECT. XVII.

## HOSPITALS.

2973. The buildings called hospitals are destined for the reception of the sick poor, for insane persons, and sometimes for particular diseases, among which old age may be enumerated, or disability from wounds, &c. in the public service, of which last class are the royal hospitals of Greenwich and Chelsea. There are some for the reception and education of foundlings, and others for the reception and delivery of pregnant women; and the term is sometimes used to denote a building appropriated to poor persons, where they have an allowance for their board and are lodged free; in short, what is otherwise called an almshouse.

2974. The ancients seem to have had no establishments like our hospitals for the sick; neither do they seem to have had asylums for those who suffered in the public service, though at Athens they were fed in the Prytaneum. In Sparta there does not appear to have been any such establishments; neither under the kings, consuls, or emperors of Rome does it seem there was any institution for the reception of poor sick persons. After the establishment of Christianity many hospitals were built by the emperors at Constantinople for poor infants, for aged persons, orphans, and strangers. To the honour of the nations of Europe, no city in it is unprovided with one or more hospitals. In Paris there are thirty-two hospitals, and in London, we believe, some few more. The governments of France, Russia, Germany, and Turkey support these institutions; but in England, with the exception of Chelsea and Greenwich Hospitals, they depend upon the charity and foundations of benevolent individuals, as at Guy's, Bartholomew's, and the other hospitals of London.

There is great reluctance often on the part of the poor to enter an hospital; and on this account we do not think that money ill bestowed which tends to impart to it an agreeable and cheerful exterior. It is almost unnecessary to insist upon a thorough warming, and, what is equally important, ventilation of the edifice: no means should be omitted to render the place wholesome, and to prevent infection spreading from one part to another. If possible, the hospitals of a city should be seated in the least populous parts, if the health of the city be consulted, or on each suburb; in which latter case the establishment would be nearer the quarter it is to serve, and more accessible in a short time in the case of accidents.

2975. The plans of some of the finest hospitals in Europe are given in Durand's *Parallèle d'Edifices*; among them may be mentioned that of Milan as a very fine example of disposition. It is indeed the most celebrated in Italy. A large portion of it remains still unfinished. The architect was Filarete, and, being commenced in 1457, it is of course in a half-Gothic sort of style. The accommodations for the men are on one side of a very large cloistered court, 152 feet wide and 204 feet long, and are in the form of a cross, 304 feet long on each side and 30 feet wide. In the intervals of the cross are four court yards, on whose remaining sides are rooms for the assistants. A canal flowing at the side answers the domestic purposes of the place, and also turns a mill for the use of the establishment. On the opposite side of the cloistral court above mentioned are similar accommodations for the women. And in the middle of the narrow side of the great cloister, opposite the entrance, is a church, which serves for the whole establishment. The cloisters of the large court and the main body of the building are in two stories, so that they form galleries of communications. This edifice has served for model to many others; and though it is now many years since we visited it, its excellence will not easily be effaced from our recollection. The hospital, given by Durand in the plates above quoted, De la Roquette, in the suburbs of Paris, designed by Poyet, was conceived on a magnificent scale, and was admirably planned. In this design each room, as well those on one side of the establishment for the males as those on the other side for the females, is appropriated to one particular disease. Each of these rooms is about 32 feet wide and 30 feet 6 inches high. Behind the beds (which are in two rows in each room) runs a passage about 3 feet 4 inches wide, which removes them so much from the walls, and allows therefore of the necessary waiting on the invalids, and hides the wardrobe attached to each bed in the window recesses. Above these passages, which are about 6 feet 6 inches high, is arranged on each side a row of windows, by which ventilation as well as light is obtained. The ground floor contains the halls and offices necessary for such an establishment. The designs for this building were made about 1788, on the instructions drawn up, after several

years' investigation, by a number of the most skilful and learned medical men of France, so as best to unite health and convenience in such an edifice. One of the conditions prescribed by their programme was the complete insulation of each apartment, as well as an easy communication by covered galleries round the building, and these were required to be of such extended dimensions that the air around should be unobstructed and circulating in every part with freedom, thus affording a wholesome promenade for the patients.

2976. The hospitals of Greenwich and Chelsea are good examples for establishments of this nature; the former, indeed, adds to its other excellencies a magnificence in the architecture worthy the object, though not so originally intended. The Hotel des Invalides at Paris is another monument worthy of all praise; and indeed we scarcely know a quadrangle more imposing than the court of this edifice with its double tier of arcades. This hospital contains 7000 veterans, and has attached to it a library of 20,000 volumes. We know not how better to close this section than with the maxims, or rather general observations, of Durand upon the subject: "*Dans des hospices,*" says the author, "*dont la disposition répondraient si parfaitement à l'importance de leur objet, on ne craindrait plus de venir chercher des secours. Leur aspect seul, si non magnifique, du moins noble et agréable, influerait sur l'efficacité des remèdes. En entrant dans des tels édifices, où tout annonce le respect que l'on porte à l'humanité, et surtout à l'humanité souffrante, on se sentirait soulagé du poids de la honte, fardeau souvent plus insupportable et plus accablant que celui du malheur même.*"

## SECT. XVIII.

### PRISONS.

2977. In considerable cities and towns, humanity, and indeed justice, demands, independent of the injury done to the morals of the public, that the same building which confines the convicted felon should not enclose the debtor and the untried prisoner, as well as him whose offence is not of an aggravated nature. Where there is a mixture of the several classes of those that have violated the laws, the young soon becomes infected by the old offender with whom he comes in contact, and returns to society, after undergoing his punishment, a much worse member of it than he was before his incarceration. In small towns, where there is only one, perhaps small, prison, the separation of the prisoners is more difficult to accomplish; but it ought always to be obtained. We hardly need say that the separation of the sexes in a prison is indispensable.

2978. For whatever class of prisoners a building is erected, salubrity and ventilation are as essential as the security of those confined. The loss of liberty is itself a punishment hard to endure, without superadding the risk of disease and death in their train, to persons who may be even innocent of the crimes with which they are charged. Besides which, the disease engendered in a gaol called the prison fever may spread into the city and carry off its inhabitants.

2979. We shall here place before the student the principal requisites which the celebrated Howard has specified for prisons. "A county gaol, and indeed every prison, should be built on a spot that is airy, and, if possible, near a river or brook. I have commonly found prisons near a river the cleanest and most healthy. They generally have not (and indeed could not well have) subterraneous dungeons, which have been so fatal to thousands; and by their nearness to running water another evil almost as noxious is prevented, that is, the stench of sewers. I said a gaol should be near a stream; but I must annex this caution, that it be not so near as that either the house or yard shall be within the reach of floods." . . . "If it be not practicable to build near a stream, then an eminence should be chosen; for as the wall round a prison should be so high as greatly to obstruct a free circulation of air, this inconvenience should be lessened by rising ground, and the prison should not be surrounded by other buildings, nor built in the middle of a town or city. That part of the building which is detached from the walls, and contains the men felons' wards, may be square or rectangular, raised on arcades that it may be more airy, and have under it a dry walk in wet weather. These wards over arcades are also best for safety; for I have found that escapes have been most commonly effected by undermining cells and dungeons. If felons should find any other means to break out of the raised ward, they will still be stopped by the wall of the court, which is the principal security; and the walls of the wards need not then be of that great thickness they are generally built, whereby the access of light and air is impeded. I wish to have so many small rooms or cabins that each criminal may sleep alone; these rooms to be ten feet high to the crown of the arch, and to have double doors, one of them iron-latticed for the circulation of air. If it be difficult to prevent their being together in the daytime, they should by all means be separated at night. Solitude and silence are favourable to reflec-

tion, and may possibly lead to repentance." . . . "The separation I am pleading for, especially at night, would prevent escapes, or make them very difficult, for that is the time in which they are generally planned and effected. Another reason for separation is, that it would free gaolers from a difficulty of which I have heard them complain: they hardly know where to keep criminals admitted to be evidence for the king; these would be murdered by their accomplices if put among them, and in more than one prison I have seen them for that reason put in the women's ward. Where there are opposite windows they should have shutters, but these should be open all day. In the men felons' ward the windows should be six feet from the floor; there should be no glass, nor should the prisoners be allowed to stop them with straw, &c. The women felons' ward should be quite distinct from that of the men, and the young criminals from old and hardened offenders. Each of these three classes should also have their day room or kitchen with a fireplace, and their court and offices all separate. Every court should be paved with flags or flat stones for the more convenient washing, it, and have a good pump or water laid on, both if possible; and the pump and pipes should be repaired as soon as they need it, otherwise the gaols will soon be offensive and unwholesome, as I have always found them to be in such cases. A small stream constantly running in the court is very desirable. In a room or shed near the pump or pipe there should be a commodious bath, with steps, (as there is in some country hospitals,) to wash prisoners that come in dirty, and to induce them afterwards to the frequent use of it. It should be filled every morning, and let off in the evening through the sewers into the drains. There should also be a copper in the shed to heat a quantity of water sufficient to warm that in the bath for those that are sickly. There should also be an oven: nothing so effectually destroys vermin in clothes and bedding, nor purifies them so thoroughly when tainted with infection, as being a few hours in an oven moderately heated. The infirmary or sick ward should be in the most airy part of the court, quite detached from the rest of the gaol, and raised on arcades. These rooms should never be without crib-beds and bedding. In the middle of the floor of each room there should be a grate of twelve or fourteen inches square, covered with a shutter or hatch at night. The sewers or vaults of all prisons should be in the courts, and not in the passages, and (like those in colleges) close boarded between the seats up to the ceiling, the boards projecting ten inches before each seat. The infirmary and sheds will not render the court unsafe, provided the walls have parapets or small *chevaux de frise*. Debtors and felons should have wards totally separate; the peace, the cleanliness, the health and morals of debtors cannot be secured otherwise. The ward for men debtors should also be over arcades, and placed on one side of the gaoler's house. This house should be in or near the middle of the gaol, with windows to the felons' and to the debtors' courts. This would be a check on the prisoners to keep them in order, and would engage the gaoler to be attentive to cleanliness and constant washing to prevent his own apartments from being offensive. A chapel is necessary in a gaol. I have chosen for it what seems to me a proper situation. It should have a gallery for debtors or women; for the latter should be out of sight of all the other prisoners, and the rest may be separated below."

2980. The above general principles are excellent, and are followed in all gaols of modern construction. The tread-mill is also introduced for punishment, as well as occasionally workshops for trades, to avoid the idleness of the prisoners. Society owes a debt of infinite magnitude to the benevolent man from whom the foregoing quotation has been taken.

2981. One of the most celebrated prisons on a panoptical system in Europe is the celebrated house of correction at Ghent. It is situated on the north side of that city, on the Coupure canal, which is bordered by a double row of large trees. A plate of the plan is given, No. 28. Durand's *Parallèle d'Edifices*. It was begun in 1773, under the reign of Maria Theresa, and is in the form of a slightly elongated octagon, in the centre whereof is a spacious court, which communicates with the different quadrangles of the edifice. Each quadrangle or ward (eight in number) has a yard, and in the centre of that, belonging to the female ward, is a large basin of water, in which the female prisoners wash the linen of the whole establishment. Each prisoner sleeps alone, in a small but well-aired room, and is employed during the day in working at the trade or business to which he or she is competent. Of the produce of such labour, government retains one half when the prisoners are detained merely for correction, six tenths when condemned to a term of imprisonment under martial law, and seven tenths when they have been sentenced to hard labour. The remainder is divided into two portions, one given weekly to the prisoners for pocket money, the other given to them on the expiry of their imprisonment, to assist their re-establishment in society. Religious service and instruction are provided; and if prisoners are destitute of the first elements of knowledge, they are taught reading, writing, and arithmetic, besides receiving other instruction. Solitary confinement is the punishment for insubordination or refractory conduct. The shops for refreshments sold to the prisoners are strictly regulated by the officers of the institution; and the profits resulting from the

sale of the different articles are reserved for rewarding the most industrious and best-behaved prisoners. The new part of the building, which has recently been completed, has cost 40,000*l.* sterling; and the whole edifice, when finished, and there is much still to be done, will contain 2600 prisoners. The defect in the institution lies in the reception of unfortunate and criminal persons of all descriptions, from the simple mendicant to the hardened murderer. It is true that those confined for heinous crimes are separated from those who have been guilty of misdemeanours; but the knowledge, on the part of all its inmates, that they to a certain extent are considered in the same predicament, must necessarily so operate on their minds as to throw down the barriers between misfortune and crime, as well as between those who are only commencing a guilty course and those who have consummated their vicious career. The Penitentiary at Milbank, in London, has been erected in some measure on the principles of the house of correction at Ghent, but its inmates are such only as have received the sentence of a criminal court. Where, indeed, the population is so great as in the metropolis of England, prisons for each class of offenders should be provided, at whatever cost. It is a duty due from the government to humanity to see that this is done.

---

## SECT. XIX.

### BARRACKS.

2982. Barracks, or buildings for the reception of the military, were common with the Romans, amongst whom they were called *castra* or camps. There were many of these at Rome and in the provinces; but the most perfect remains of Roman barracks are at Pompeii, of which sufficient remains exist to give us a general idea of their distribution. The distribution was in an oblong, and the quadrangle or parade was surrounded by a covered gallery on columns. From this gallery was the entrance to the rooms of the soldiers, but it also served as an ambulatory for exercise. Beyond the further end, opposite the entrance, was a theatre. A more perfect knowledge, however, than we have of the barracks of the ancients, would not assist us in providing better for the military in these days; indeed, there is little required to be said in this place on the subject, inasmuch as in respect of healthy situation, perfect ventilation, and security against fire, the principles which chiefly regulate the disposition and distribution of a hospital, are equally applicable in building barracks, which are, in truth, *hospitia* for the reception of men in health instead of sick persons. Private soldiers in barracks, however, usually sleep on inclined planes, raised from the floor, and at the head abutting against the wall, instead of being provided with separate beds. In Paris there are no less than thirty buildings used as barracks. The details necessary to be provided are a canteen or public-house, for the use of the privates and non-commissioned officers; a spacious mess-room and separate apartments for the officers, and an infirmary. In cavalry barracks, proper stabling and a riding-house of large dimensions must of course be added. For cleanliness, all the yards should be paved, and the utmost precaution taken for carrying off all filth and waste water by means of drainage into a sewer, having a considerable fall from the place. This will, as much as anything, tend to the healthiness of the building.

---

## SECT. XX.

### PRIVATE BUILDINGS — GENERAL OBSERVATIONS.

2983. Private buildings differ in their proper character from public buildings as much as one public building differs in character from another not of the same kind. The ends in both, however, in common, are suitableness and utility. The means are the same, namely, the observance of convenience and economy. The same elements are used in the formation of one as of the other; hence they are subject to the same principles and the same mechanical composition. Distribution, which is usually treated distinct from decoration and construction, and very improperly so, as applied to private edifices, is conducted as for public buildings, that is, as we have said, with a view to utility and economy.

2984. If the student thoroughly understand the true principles of architecture, — if he possess the facility of combining the different elements of buildings, or, in other words, fully comprehend the mechanism of composition, which it has in a previous part of this Book (III.) been our object to explain, nothing will remain for him in the composition of private buildings, but to study the special or particular conveniences required in each. There are some quaint old aphorisms of Dr. Fuller, prebendary of Sarum, which are so

applicable to all private buildings, that we shall not apologise for transferring them to our pages.

2985. "First," he says, "let not the common rooms be several, nor the several rooms common; that the common rooms should not be private or retired, as the hall (which is a *pandochæum*), galleries, &c., which are to be open; and the chambers, closets, &c. retired and private, provided the whole house be not spent in paths. Light (God's eldest daughter) is a principal beauty in a *building*; yet it shines not alike from all parts of the heavens. An east window gives the infant beams of the sun, before they are of strength to do harm, and is offensive to none but a sluggard. A south window in summer is a chimney with a fire in it, and stands in need to be screened by a curtain. In a west window the sun grows low, and ever familiar towards night in summer time, and with more light than delight. A north window is best for butteries and cellars, where the beer will be sour because the sun smiles upon it. Thorough lights are best for rooms of entertainments, and windows on one side for dormitories."

2986. "Secondly, as to capaciousness, a house had better be too little for a day than too big for a year; therefore houses ought to be proportioned to ordinary occasions, and not to extraordinary. It will be easier borrowing a brace of chambers of a neighbour for a night, than a bag of money for a year; therefore 'tis a vanity to proportion the receipt to an extraordinary occasion, as those do who, by overbuilding their houses, dilapidate their lands, so that their estates are pressed to death under the weight of their house."

2987. "Thirdly, as for strength, country houses must be substantives, able to stand of themselves, not like city buildings, supported and flanked by those of their neighbour on each side. By strength is meant such as may resist weather and time, but not attacks; castles being out of date in England, except on the sea-coasts, &c. As for moats round houses, 'tis questionable whether the fogs that arise from the water are not more unhealthful than the defence that the water gives countervails, or the fish brings profit."

2988. "Fourthly, as for beauty, let not the front look asquint upon a stranger, but accost him right at his entrance. Uniformity and proportions are very pleasing to the eye; and 'tis observable that freestone, like a fair complexion, grows old, whilst bricks keep their beauty longest."

2989. "Fifthly, let the offices keep their due distance from the mansion-house; those are too familiar which presume to be of the same pile with it. The same may be said of stables and barns; without which a house is like a city without works, it can never hold out long. It is not only very inconvenient, but rather a blemish than a beauty to a building, to see the barns and stables too near the house; because cattle, poultry, and suchlike must be kept near them, which will be an annoyance to a house. Gardens ought also to be disposed in their proper places. When God planted a garden eastward, he made to grow out of the ground every tree pleasant to the sight and good for food. Sure he knew better what was proper for a garden than those who now-a-days only feed their eyes and starve their taste and smell." The same honest old dignitary (would we had some such in these days!) says, "He who alters an old house is ty'd as a translator to the original, and is confined to the fancy of the first builder. Such a man would be unwise to pull down a good old building, perhaps to erect a worse new one. But those who erect a new house from the ground are worthy of blame if they make it not handsome and useful, when method and confusion are both of a price to them."

## SECT. XXI.

### PRIVATE BUILDINGS IN TOWNS.

2990. The common houses of the town are not those which will engage our attention. In London, and indeed throughout the towns of England, the habits of the people lead them to prefer separate houses for each family, to one large one in which several families may be well lodged, or, in other words, they prefer rows of mean-looking buildings, with holes in the walls for windows, to the palatial appearance which results, in Paris and most of the other cities in Europe, from large magnificent buildings with courts, and capable of accommodating a number of different establishments. The section will be confined chiefly to the arrangement of a house of the first class; and from what will be said, sufficient hints may be drawn for the composition of those in a lower class.

2991. The private buildings in a town are often in their composition beset with difficulties which do not occur in those of the country, where the extent of site is freer and ampler. These, therefore, may be isolated, and receive light from every side. Their offices may be separated from the main house, and the parts may be disposed in the simplest possible manner; but in cities the site is generally more or less restricted, often very

irregular in form, and generally bounded by party walls. Yet, with all these obstacles, it is necessary to provide almost as many conveniences as are required in a country house; whence the disposition cannot be so simple in its application as where there is no restraint. All that can be done is to make it as much so as the nature of the spot will permit, and to produce the maximum of comfort which the site affords.

2992. Nothing must be considered below the attention of an accomplished architect, nor anything above his powers; he ought as cheerfully to undertake for the proprietor the conduct of the meanest cottage as of the most magnificent palace. Little will be requisite to be said on the common houses of London, or other cities and towns in which there are seldom more than two rooms and a closet on a floor, with an opening behind. These may be varied; but the general mode is to construct them with a kitchen in a floor sunk below the ground, and a room behind, serving for a variety of purposes; an area in front, with vaults under the street, and the same often in the rear of the house. The space opposite the descending stairs will form a dark closet; and the privies, and wine and beer cellars, with other small offices, are provided in the vaults. On the ground floor there is rarely more than a passage on one side, which conducts to a staircase; and this requiring more width than the passage itself, the best room on this floor is placed in front, and the back is a smaller room, often opening on a small light closet still further in the rear. A yard is supposed behind, by which light is obtained for the back room. On the one-pair and other floors the passage becomes unnecessary as an access; the drawing or front room therefore runs over it, and becomes larger, capable, in the upper floors, of subdivision for bedrooms, or other purposes, as may be required; and the back rooms, with their closets, if carried up, follow the form of those on the ground floor. Though little variety may be the result of the restricted space to which this species of house is usually confined, the addition of four or five feet either way will enable an intelligent architect to throw in closets and other conveniences which are invaluable, as relieving a small house from the pressure which otherwise will exist in the different apartments. But this will be obvious to the practical man, unless he walks about blindfold. The houses we have just described may stand upon a site of about twenty feet by thirty feet, independent of the vaults in front and rear, and the back light closet, which is an invaluable appendage to a house of this description; which is the scale of a second-rate house.

2993. Of the next higher rate of house the varieties are too great to be described, because the extent of the largest arrives at what would be called a palace on the continent. But, taking a mean between that just described and that last named, we may take one similar to a moderate one in Portland Place for example. In such a one we must provide, on the basement or sunk story, vaults under the street for beer, coals, wood, privies, and the like, the refuse or dust of the house. The body or corps de logis on this floor must contain housekeeper's room, servants' hall, rooms for butler and head footman, wine cellar, closets for linen, strong room for plate, with closets and other conveniences for the household. The ascending staircase must also have a space set apart for it. In the rear, under the open area behind, will be placed a kitchen, scullery, and the larder, with the other appendages of this part of the household; an area, covered, where the communication with the rest of the floor is made between the body of the house and the offices in question. Beyond the kitchen are often vaults (though the disposition is sometimes otherwise), over which the stables and coachhouses are placed, opening on the ground floor or to a mews parallel to the street in which the house is situate. The ground floor of this disposition has usually a dining-room in front, with a good-sized hall at its side, leading to a staircase which ascends in direction of the long side of the house; and this is necessary when the rooms above are to communicate by folding doors. In some old houses, however, the staircase ascends between the front and back rooms, and a back staircase is provided by the side of it. But more commonly this is placed beyond the principal stairs, to allow of throwing the drawing-rooms into one. In rear of the dining-room is often placed a library for the gentleman of the house; and beyond this, and further than the back stairs, when the lateral staircase is used, a waiting-room, at the rear of which a water-closet may be placed, with a door from it to the area over the kitchen; or there may be a communication of this sort from the waiting-room, which may serve the purpose of access to the stables. On the one-pair floor the disposition will be two drawing-rooms, a boudoir over the waiting-room, and beyond this a water-closet. On the two-pair floor two bed-rooms, each with a dressing-room, or three bed-rooms and one dressing-room, and a bath-room and water-closet. Above this four bed-rooms and closets may be obtained; and, if necessary, rooms in the roof in addition. For a good house of this class, with the offices, the plot of ground should not be much less than 100 feet by 30.

2994. Of the first class of houses, as a model may be taken the town-house, in Piccadilly, of His Grace the Duke of Devonshire, which, with the offices and court-yard in front, covers an area extending about 231 feet towards the street, and 188 feet in depth, whereof the house itself occupies a frontage of 163 feet and a depth of 188 feet, and opens on to a large garden in the rear. On the east side of the court-yard are dis-

posed the kitchen and other domestic offices, opposite where to, on the west side, stand the coach-houses and stabling. The basement of the house contains apartments for the various persons attached to such an establishment. The principal floor to which the ascent is by an external staircase, contains an entrance-hall, 35 feet by 30 feet, and communicates to an apartment on the west side, 33 feet by 22 feet, leading to the south-western corner room, which is 20 feet square. On the north of the last is a room, making the north-west angle of the building, and this is 40 feet by 20 feet. On the east side of this last, and facing the north, is a room 33 feet by 23 feet, and in the centre of the north front, corresponding with the width of the hall, is an apartment 30 feet by 23 feet 6 inches. To the east of the last is a room 33 feet by 24 feet, and east of that, forming the north-east angle, is a small room 20 feet square. Thus far these rooms, seven in number, are all *en suite*, but this is in some measure interrupted by the remainder of the east flank, which is filled with three smaller rooms. To that of them, however, at the south, which is 20 feet square, a passage is preserved, and from that you enter another room, 23 feet by 22 feet, which once more brings you back to the hall. The staircases are between the north and south rooms on each side of the hall. Above this floor are the lodging rooms, &c. The superficial area of all the reception rooms on the principal floor, added together, amounts to 5708 feet.

2995. Burlington-house, in some respects,—for instance, in its beautiful front court,—may be considered superior to that we have just described. It can be hardly necessary to add that, in such edifices, rooms must be provided for steward, butler, housekeeper, stillroom-maid, servants' hall of good dimensions, valets, ladies' maids, &c.; for a muniment room and plate, both of which must be fire-proof. Baths also should be placed on the chamber floor, with other conveniences which will occur to the architect. The rooms for pictures, if possible, should be on the north side of the building. To Lord Burlington the English aristocracy is much indebted for the introduction of the Italian style into their dwellings; for the taste of Jones had almost passed away when the talented nobleman in question gave a new impetus to proper distribution and decoration. Plans and elevations of Devonshire-house are given in the *Vitruvius Britannicus*, which contains other town houses of importance well worth the student's attention.

## SECT. XXII.

## PRIVATE BUILDINGS IN THE COUNTRY.

2996. Of first-class private buildings in the country, we apprehend we cannot furnish better hints than by describing that of Kedleston, in Derbyshire, erected for Lord Scarsdale by Robert Adam. There are others which are larger, but we do not think any superior in distribution and effect. The plans and elevations of it are to be seen in the *Vitruvius Britannicus* above mentioned. The main body of the house M (*fig. 1038.*), is about 136 feet by 105 feet; and at each angle are quadrants of communication to the four wings A, B, C, and D, which are each about 70 feet by 54 feet. On the basement story of the main building are a large and small sub-hall in the centre, the former 67 feet 3 inches by 42 feet, and the latter 42 feet by 40 feet 7 inches. On the right of these are disposed a butler's room, 22 feet 6 inches by 17 feet 9 inches; a housekeeper's room, and a steward's room, 30 feet by 21 feet 6 inches. On the left, a bath, a gun-room, 23 feet 9 inches by 23 feet 7 inches; a smoking parlour, 28 feet by 17 feet 9 inches; a boot-room, 22 feet 6 inches by 17 feet 9 inches, besides closets and staircases, &c. on either side. The wing B contains the stables, a chapel, and other apartments. C, sleeping and other rooms, eight in number, with a staircase which conducts to the corridor in the corresponding quadrant. D contains the kitchen and its requisite accessories, and a servants' hall. This wing has also a staircase to its corresponding corridor in the quadrant, which attaches it to the main body. On the principal story, the main body M has at the entrance, which is in the centre, and approached by a noble flight of steps, a magnificent hall, 69 feet 3 inches by 42 feet, at the end whereof is a saloon 42 feet diameter. To the right, entering from the hall, is the principal staircase, beyond which, laterally, is a bed-chamber 33 feet by 22 feet, with its accessories; and on its end, towards the back front, are ante-rooms, and towards the front the dining-room, whence by the corridor is access to the kitchen in the wing D, and from the ante-rooms above mentioned the corresponding corridor on that side leads to a conservatory in the back front of the wing, and the upper part of the chapel. On the left-hand side of the hall, with windows in the left flank of the main body, is the

Fig. 1038.

drawing-room, 44 feet by 28 feet; at the end towards the rear is a library, which is continued in the corridor leading to the wing A, wherein is a music gallery, 66 feet by 18 feet, with other rooms and a staircase. On the end of the drawing-room, towards the front, is a music room, 36 feet by 24 feet, whence the corridor leads to Lord Scarsdale's bedroom, 18 feet square, with dressing-rooms, and the lady's library, which, on this floor, are in the wing C. The wing D is occupied by the upper part of the kitchen, a laundry, 35 feet by 18 feet, and some bedrooms, to which access is by a gallery over part of the kitchen. The main body and wings contain a story over what has been last described, chiefly for chambers. We have before (in the First Book, *figs.* 221, 222.) noticed the splendid hall and salon, which occupy the height of the whole building, and are, though somewhat faulty in detail, very finely-conceived and well-proportioned apartments. The former is 40 feet high to the top of the cove, and the latter 55 feet to the level of the eye of the dome. Though the elevations exhibit defects, we are not inclined to quarrel with them in a dwelling which deserves rather the name of a palace than of a country house.

2997. England abounds with country seats of this class: among them is Holkham, which has already been mentioned in the First Book (511.); but we know none for disposition that can claim superiority over that which we have above described at length, from which the student may derive much information on the requirenda in a mansion of the first class. It is to be understood that we here intend modern buildings. The houses of the times of Elizabeth and James are many of them magnificent structures, but the comfort introduced into houses of later date leaves them, independent of their picturesque beauty, far behind the buildings of Kent, Carr, James, and many others. Blenheim is monumental in its design, and properly so, and hence does not fall within the category of the section.

2998. There are, of course, many intervening degrees between the mansion we have just described and the villa of the retired banker or merchant: it would be impossible to state them in detail. We have given the maximum in the above case, and we shall now give the minimum for the class last mentioned.

2999. The smallest site of ground on which a villa can be well designed is, supposing it an oblong, about 80 feet by 56 to 60 feet. This on the principal floor will admit of a hall, a salon or ante-room, which may lead to the principal apartments, a drawing-room, two secondary drawing-rooms, one whereof may be appropriated to the reception of a billiard table, a good dining-room, not less than 30 feet by 20 feet, a library of equal size, with other rooms, suitable to the particular taste of the proprietor, and the conveniences and accessories which such a building requires. The ground, supposing the domestic offices to be under the principal floor, should be raised, so that they need not be much sunk below the general level of the land. If the building be seated on rising ground, a little more sinking may be allowed than under other circumstances, provided the lower story be protected by dry drains all round the building, to prevent the earth lying against the walls, because drainage, the most important of all things in a building, may then be obtained easily by the natural fall of the ground. The plot we have mentioned will admit of all the offices below, which are necessary for the service of a good-sized family, and above, with only one story above the principal one, will afford a pretty fair allowance of dormitories; but if a concealed story for servants be practised in the roof, there are few establishments on a common scale for which, on the plot, accommodation may not be provided by a skilful artist. The stables and coach-houses and the greenhouses should stand apart. Some persons like to have these communicating with the villa itself; but the practice is destructive of symmetry, and very injurious (except in the villa on an irregular plan, which then rather approaches to the *cottage orné*) to the general effect of the architecture.

3000. The villas at Foot's Cray and Mereworth, imitations of Palladio's Villa Capra, so often mentioned in this volume, and represented in *fig.* 1018., are the maxima of villas: beyond this the villa becomes a mansion, and must be treated as one on a scale more or less grand, as the means of the proprietor allow the architect to provide for his wants. All precepts, however, on this head are valueless, because the architect is regulated so much by the convenience required. He must possess himself fully of that, and attending to the general rules given throughout the work, but especially in this Third Book, he will find little difficulty in fulfilling the commission with which he is intrusted. Among other matters let him well inform himself of what has been done, and make himself master of the points involved in domestic economy, from the lowest to the highest grade, and he cannot, using that information, fail of giving his employer that satisfaction which is the first care that should animate him.

3001. It is not our intention to touch upon the *cottage orné*, as it is called. This is a nondescript sort of building, subject only to rules which the architect chooses to impose upon himself. The only point to be attended to, after internal comfort has been provided for, is to present picturesque effect in the exterior. It is a branch of practice requiring a minimum of mind on the part of the architect, and for the successful execution of which the landscapes of Gaspar Poussin will give him enough hints to stud a province with them.

## SECT. XXIII.

## FARM-HOUSES.

3002. The mere building denominated a farm-house is simple enough in its distribution, and scarcely justifies a section here, because the persons engaged in agriculture have generally the best notion of the mode of suiting it to their own particular business and the nature of the farm they occupy. It is first to be considered whether it is expedient to place it close to the other buildings of the farm, such as the barns, stables, and stalls for cattle, &c. If so, it should be designed in character with them, and a large space of ground is enclosed for the formation of a farm-yard; which, notwithstanding the seemingly repulsive nature of the subject, may be made a very picturesque composition as a whole. The farm-house itself, though it must be sufficiently large to accommodate the family of the farmer, should be restricted in the size of its rooms and the extent of its plan by the magnitude of the farm, it being altogether an absurdity to plan a large house on a small farm, not only because of the original cost, which the rent of the land will not justify, but because of the cost of the annual repairs which a large building entails beyond those of a smaller one. The same observation applies to the farm buildings themselves, which in extent must be regulated by the size of the farm cultivated. It is moreover to be considered, in respect of the latter, whether the farm be grazing or arable. In the first case more provision of cattle sheds must be afforded; in the latter case more barns must be allotted to the cultivator. These, however, are matters upon which the architect receives his instructions from the proprietor, and whereon, generally speaking, he is himself incompetent to form a correct judgment.

3003. In the commonest farm-houses the external door may open to a plain passage, at the end whereof the staircase may be placed. On one side of the passage may be a common kitchen, and on the other side the better or larger kitchen, serving also as a parlour for the farmer and his family. Beyond these, on one side, may be placed the pantry, and on the other side the dairy-room, the last being much larger than the former, and being on the side of the parlour or best kitchen, not so liable to the heat. To these, as needful, may be added more rooms on the ground floor; the upper story being divided into bed-chambers for the family, with garrets over them for the servants. The kitchens should be placed upon arched cellars on several accounts, not the least of which is that the farmer should have the means of preserving in good condition the malt liquor or cyder which is the principal beverage of his establishment. It is a sad mistake on the part of landed proprietors, though common enough, to think that such buildings are not only below the care of an architect, but that he is too ignorant of the wants of the farmer to be competent to the task; if, however, he will reflect for a moment, he must admit that the artist who can make the most of a large plot of ground, with numberless requirements in the accommodation, is not less able to turn to the greatest advantage for the comfort of the occupier even a small farm-house.

3004. In the erection of a larger farm-house the choice of the site, as before, must depend on the nature of the ground and the situation of the farm. Health and convenience are the primary governing matters. It must never be placed where it cannot be well drained. It should be central to the land, and as near the road as the conditions will admit. For such a building the principal door may open into a moderately wide passage, having therein a staircase to the upper rooms. On the right of the passage a common kitchen may be provided for the family, and on the left a room somewhat larger, which in very small farm-houses used to be called the best kitchen, but which in this may be really the parlour, where the family may sit retired from the servants. Under these, cellars, as above mentioned, may be provided. On the ground floor we may now add a bakehouse and scullery to the pantry and dairy provided in the first scheme, as also closets and such conveniences for the housewife. The floor above may be extended over the additional rooms just mentioned, thus giving lodging room to a larger number of persons than to those contemplated in the first scheme. "In this manner," says Ware, in his *Complete Body of Architecture*, folio, London, 1756, "the young architect will very easily see how to enlarge or contract his plan for the building of farm-houses, according to the intended bigness." . . . "They all consist of the same number of rooms, and in general of the same number of offices; this is where the bare article of convenience for farming is concerned. Where the inhabitant is grown rich, and intends to live in another manner, he may add what he pleases, which the architect may adopt." . . . "It is then no longer to be considered a farm-house, but as the house of some person of fortune, who intends to live as those independent of business do, but withal to have some farming in his eye." When the farm-house comes to this extent it trenches hard upon the condition of the villa, though not quite reaching it, because the latter includes many provisions for a refined mode of living which the yeoman, the pride of England, does not require; a class which, we fear, the manufacturing and commercial classes are fast annihilating.

## SECT. XXIV.

## COTTAGES.

3005. "Estates," observes Kent, (*Hints to Gentlemen of Landed Property*, 8vo. London, 1776,) "being of no value without hands to cultivate them, the labourer is one of the most valuable members of society: without him the richest soil is not worth owning." It follows, then, that his condition should be most especially considered, and it is a duty on every country gentleman to take care that the labourers on his estate are so considered as to be made at least comfortable. "The shattered hovels," says the same author, "which half the poor of this kingdom are obliged to put up with, is truly affecting to a heart fraught with humanity." . . . "The weather penetrates all parts of them, which must occasion illness of various kinds, particularly agues; which more frequently visit the children of cottagers than any others, and early shake their constitutions." . . . "We are careful of our horses, nay, of our dogs, which are less valuable animals; we bestow considerable attention upon our stables and kennels, but we are apt to look upon cottages as incumbrances and clogs to our property, when, in fact, those who occupy them are the very nerves and sinews of agriculture." We fear the neglect of the comfort of the cottager has given a greater impulse to poaching and other crimes than his natural propensities have induced. This, however, is not a matter for discussion here. It is not to be supposed that we mean the labourer is to be placed in an expensive dwelling; a difference of rank must exist; and if the whole revenue of the country were divided among the population per head, it would be seen (as M. Dupin has recently shown in a most eloquent and sound address delivered in Paris as respects France) that the division of it per day, after allowing for the expenses of the most economical government that could be devised, would be such as would not satisfy the lowest class of labourer, much less the ingenious mechanic. This is a matter so susceptible of proof, and so proper to be generally promulgated, that we have here gone a little out of our way lest we should be considered too urgent with respect to the cottager.

3006. No cottage ought to be erected which does not contain a warm, comfortable, plain room, with an oven to bake the bread of its occupier; a small closet for the beer and provisions, two wholesome lodging rooms, one whereof should be for the man and his wife, and the other for his children. It would be well always, if possible, that the boys and girls in a cottage should be separated; but this unfortunately entails an expense, and perhaps is not so materially necessary, because the boys find employment at an early age. A shed for fuel should be attached.

Cottages should always be placed in sheltered spots, and as near as possible to the farm where the labourer is employed. The wear and tear of a man is not very dissimilar to that of an engine, and it tends as much to the interest of the farmer as it does to the comfort of the labourer that all unnecessary fatigue be avoided.

3007. In the erection of cottages it is not only more economical, but more comfortable to the occupiers, that they should be built double, or in twos at least. In those provinces where brick or stone can be obtained they should never be constructed with timber, and tiles, if they can conveniently be had, should always supersede thatch. Further observation on this subject will be unnecessary, for we have ill delivered the principles of our art if the student be not now prepared to carry out the few hints on the subject of cottages, — buildings, in point of fact, of importance paramount to the palace which the sovereign inhabits.

The following remarks are from a very talented and practical person, J. C. Loudon, Esquire.

"The essential requisites of a comfortable labourer's cottage may be thus summed up: —

"1. The cottage should be placed alongside a public road, as being more cheerful than a solitary situation, and in order that the cottager may enjoy the applause of the public when he has his garden in good order and keeping.

"2. The cottage should be so placed that the sun may shine on every side of it during the day throughout the year, when he is visible. For this reason, the front of the cottage can only be parallel to the public road in the case of roads in the direction of north-east, south-west, north-west, and south-east; in all other cases the front must be placed obliquely to the road, which, as we have previously shown, is greatly preferable to having the front parallel to the road.

"3. Every cottage ought to have the floor elevated, that it may be dry; the walls double or hollow, or battened, or not less than eighteen inches thick, that they may retain heat; with a course of slate or flagstone, or tiles bedded in cement, six inches above the surface, to prevent the rising of damp; the roof thick or double, for the sake of warmth; and projecting eighteen inches or two feet at the eaves, in order to keep the walls dry, and to check the radiation of heat from their exterior surface.

"4. In general, every cottage ought to be two stories high, so that the sleeping rooms may not be on the ground floor; and the ground floor ought to be from six inches to one foot above the outer surface.

"5. The minimum of accommodation ought to be the kitchen or living room, a back kitchen or wash-house, and a pantry, on the ground-floor, with three bedrooms over; or two rooms and a wash-house on the ground-floor, and two bedrooms over.

"6. Every cottage, including its garden, yard, &c., ought to occupy not less than one sixth of an acre; and the garden ought to surround the cottage, or at all events to extend both before and behind. In general, there ought to be a front garden and a back yard, the latter being entered from the back kitchen, and containing a privy, liquid manure tank, place for dust and ashes, and place for fuel.

"7. If practicable, every cottage ought to stand singly, and surrounded by its garden; or at all events not more than two cottages ought to be joined together. Among other important arguments in favour of this arrangement, it may be mentioned that it is the only one by which the sun can shine every day on every side of the cottage. When cottages are joined together in a row, unless that row is in a diagonal direction with reference to a south and north line, the sun will shine chiefly on one side. By having cottages singly or in pairs, they may always be placed along any road in such a manner that the sun may shine on every side of them, provided the point be given up of having the front parallel to the road, a point which in our opinion ought not for a moment to be put in competition with the advantages of an equal diffusion of sunshine.

"8. Every cottage ought to have an entrance porch for containing the labourer's tools, and into which, if possible, the stairs ought to open, in order that the bedrooms may be communicated with, without passing through the front or back kitchen. This, in the case of sickness, is very desirable, and also in the case of deaths, as the remains may be carried down stairs while the family are in the front room.

"9. The door to the front kitchen or best room should open from the porch, and not from the back kitchen, which, as it contains the cooking utensils and washing apparatus, can never be fit for being passed through by a stranger, or even the master of a family, where proper regard is had by the mistress to cleanliness and delicacy.

"10. When there is a supply of clear water from a spring adjoining the cottage, or from some other efficient source, then there ought to be a well or tank, partly under the floor of the back kitchen for drawing it up for use, as hereafter described in detail. The advantages of having the tank or well under the back kitchen are, that it will be secure from frost, and that the labour of carrying water will be avoided.

"11. The privy should always be separated from the dwelling, unless it is a proper water-closet, with a soil-pipe communicating with a distant liquid manure tank or cesspool. When detached, the privy should be over or adjoining a liquid manure tank, in which a straight tube from the bottom of the basin ought to terminate; by which means the soil basin may always be kept clean by pouring down the common slops of the house. No surface being left from which smell can arise, except that of the area of the pipe, the double flap, to be hereafter described, will prevent the escape of the evaporation from this small surface, and also ensure a dry and clean seat.

"12. The situation of the liquid manure tank should be as far as possible from that of the filtered water tank or clear water well. It should be covered by an air-tight cover of flagstone, and have a narrow well adjoining, into which the liquid should filter through a grating, so as to be pumped up or taken away without grosser impurities, and in this state applied to the soil about growing crops.

"13. In general, proprietors ought not to intrust the erection of labourers' cottages on their estate to the farmers, as it is chiefly owing to this practice that so many wretched hovels exist in the best-cultivated districts of Scotland and in Northumberland.

"14. No landed proprietor, as we think, ought to charge more for the land on which cottages are built than he would receive for it from a farmer if let as part of a farm; and no more rent ought to be charged for the cost of building the cottage and enclosing the garden than the same sum would yield if invested in land, or, at all events, not more than can be obtained by government securities.

"15. Most of these conditions are laid down on the supposition that the intended builder of the cottage is actuated more by feelings of human sympathy than by a desire to make money; and hence they are addressed to the wealthy, and especially to the proprietors of land and extensive manufactories or mines."

3008. The preceding observations of Mr. Loudon are extracted from a "Report to Her Majesty's principal Secretary of State, from the Poor Law Commissioners, on an Enquiry into the Sanitary Condition of the Labouring Population of Great Britain." 8vo. London, 1842. We regret that this Report was not published in time for us to notice one portion of it under its proper head, namely, that of sewers, a subject on which a very lengthened experience has enabled us to acquire some knowledge. The writer of the Re-

port, who himself cannot be supposed at all qualified for such a task, has recommended forms for sewers which practice has proved to be exceedingly inconvenient; and has moreover given to a gentleman having, as he says, "the experience and qualifications of an engineer," the credit of having invented a method of flushing the sewers, and of carrying off all the refuse by water: a scheme so far from novel that we ourselves have used it on a very extensive scale for the last thirty-five years at least. We have thought it right here to notice this Report, which in many other particulars is ill and carelessly drawn up. It is much to be regretted that it was not committed to more competent hands; we mean such parts as relate to the sifting and arrangement of the evidence whereon it is founded. But this is the course of things in this country: a briefless barrister, without the least preparatory education for the task, delivers opinions *ex cathedra*, on which a scientific person would pause. "Thus fools rush in where angels, &c." — but the quotation is trite.

# APPENDIX.

## I. — GOTHIC OR POINTED ARCHITECTURE.

### SECT. I.

#### GENERAL REMARKS ON POINTED ARCHITECTURE, IN RELATION TO ITS SYMMETRY AND STABILITY.

THE pontificate, towards the end of the tenth century, of a Benedictine monk, named Gerbert, afterwards known under the name of Sylvester II., and whose life, if Platina (*Lives of the Popes*) may be relied on, was not of the most virtuous character, seems to have induced an extraordinary change in the arts. Gerbert was a native of Auvergne, and, under Arabian masters at Cordova and Grenada, applied himself to, and became a great proficient in, mathematical learning. He afterwards appears to have settled at Rheims, and to have there planted a school which threw out many ramifications. The scholars of the period were confined to the clergy, and the sciences, having no tendency to injure the Church, were zealously cultivated by its members.

In the twelfth century, the *Elements of Euclid* became a text book, and though this country was then behind the Continent, as respected the art of architecture, there is good reason for believing it was by no means so in regard to proficiency in mathematics, inasmuch as the Benedictine monk, Adelard of Bath, is known to have been highly distinguished for his acquirements in them.

In the eleventh century, architecture, considered as an art, was little more than a barbarous imitation of that of ancient Rome, and in it, all that appears tasteful was, perhaps, more attributable to the symmetry flowing from an acquaintance with geometry, than the result of fine feeling in those that exercised it. It was adapted to religious monuments, with great modifications; but the materials and resources at hand, no less than the taste of those engaged in it, had considerable influence on the developments it was doomed to undergo. The sculptures of the period were borrowed largely from the ancients, and among them are often to be found centaurs and other fabulous animals of antiquity.

The first crusade had made the people of Europe acquainted with the East, and in the twelfth century the result of the knowledge thus acquired was manifest in France, England, and Germany; it could however scarcely be expected that the art would emerge otherwise than slowly under the hands of the churchmen, who were the principal practitioners. It is difficult to assign the date at which the renowned association of Freemasons had its origin: on all hands it seems agreed that we are indebted to it for the noble structures of the middle ages. The antiquity claimed by the Freemasons of this age is too absurd for serious discussion. It appears reasonable to assume, that as the power of the Church was sinking, that of the Freemasons rose into life, and at the same time the laity increased in their rank and standing with society. The germs of the body were, however, previously in existence; for it is well authenticated (*De Beka, De Episcopis Ultraject.*) that, in the eleventh century, a certain Bishop of Utrecht was killed by the father of a young Freemason, from whom the prelate had extracted the mystery (*arcana mysterium*) of laying the foundations of a church. The period at which arose the celebrated *Confraternité des Ponts*, founded by St. Benezet, is known to have been towards the latter end of the twelfth or the beginning of the thirteenth century, and it is not unlikely that it was a branch of the great masonic association. It is also worthy of notice, that the period in question coincides with the introduction of the pointed arch simultaneously in the different countries of Europe, as though they were all actuated by one general feeling, and directed and guided by one powerful and governing body with whom it seems to have originated. The association of Freemasons had, however, its types at a period extremely remote. Among the Romans, and still earlier, among even the Greeks, existed corporations (if they may be so called) of artificers and others; such were Numa's *Collegia Fabrorum* and *Collegia Artificum*, who made regulations for their own governance. These *collegia* were much in favour with the later Roman emperors, for in the third and fourth centuries we find that architects, painters, and sculptors, and many of the useful artificers, were free from taxation. The downfall, however, of the eastern and western empires, involved them in one

common ruin, though it did not actually extinguish them. There is said still to exist in England a document, alleged to be the constitution confirmed in 926 to the corporations of architects by King Athelstan, through his brother Edwin, but where it is deposited nobody seems to know: the story is doubtless a fable. Up, however, to 1425, it is clear they existed in this country, inasmuch as the statute of 3 Henry VI., which is to be seen on the Rolls of Parliament, prohibits their meeting in chapters. A perusal of the statute, which is very short, shows that up to that time they had continued to enjoy privileges, amounting almost to a building monopoly in this country. In an indenture of this reign, between the churchwardens of a parish in Suffolk and a lodge or company of Freemasons, it was stipulated by the latter that each mason should be provided with a pair of white leather gloves and a white apron, and, moreover, that the parish should erect a lodge, properly tiled, for the prosecution of the works. Some have imagined that the concealment of their modes of arrangement of arch stones was the chief object of their association, but there can be no doubt that the whole science of construction was studied and taught in the lodges. Others have thought that they inclined to Manicheism, of which the sects were numberless: but we think they had enough to engage their attention, without discussing whether all things were effected by the combination or repulsion of the good and the bad; or that men had a double soul, good and evil; or that their bodies were formed, the upper half by God, and the lower half by the devil.

How the laity managed to insinuate themselves into these corporations, which, until the thirteenth century, consisted of the clergy only, does not appear; but it is pretty certain that about this time the lay got the better of the sacerdotal architects, were received into favour, and protected by the public. Though the Freemasons, as a body, were not hostile to the Church, by which they were viewed with a jealous eye, they were inveterate enemies of the clergy, and more particularly of the monks. This is abundantly seen in the ridicule and grotesque lampoons bestowed on them in the sculptures of the thirteenth century. As the laity became contributors towards the monuments of the time, it was induced to obtain some control by the employment of lay architects, and the weakness of the Pope, whose authority had been considerably diminished during the twelfth century, tended likewise to a similar end. As an instance of the extreme length to which the ridicule of the priests was then carried, we have at Strasburg the representation of an ass saying mass, and, at it, being served by other animals.

It appears that while the art was in its practice confined to the clergy, their taste was bounded by the semicircular arch, and that the introduction of the pointed one, and the period of the acquisition of power by the Freemasons, were coeval; whence it came, or whether it was the invention of that society, has not as yet been satisfactorily answered. In glancing over the many writers on this subject, it is amusing to see the difference of opinion that exists among them. For instance, twenty are of opinion that it originated in Germany; fourteen, that it was of Eastern or Saracenic origin; six, that it arose from the hint suggested by the intersection of the Norman arches; four, that it was the invention of the Goths and Lombards; and three, that its origin was in Italy. Sprung, however, from whatever place, it appears to have given in every sense an independence to the art not before belonging to it, and to have introduced principles of far greater freedom, in respect of the ratio of points of support to the whole mass, than were previously exhibited or probably known.

M. Michelet (*Histoire de France*) observes, "Or, lors de l'apparition de l'ogive en Occident vers 1200, Innocent III. est le dernier rayon de cette puissance universelle, le pouvoir de l'Eglise Catholique s'affaiblit. La tentative des ordres des mendiants, des pères prêcheurs est infructueuse. Le pouvoir des prêtres tombe dans la main des laïques. La puissance du droit canonique, de ce robuste auxiliaire de l'Eglise, s'efface en France devant ces lois sages faites par le pieux Roi St. Louis, et ses établissements immortels servent de code nouveau à ses sujets. En Angleterre le Roi Jean-sans-terre donne, en 1215, la grande Charte. En Allemagne, au commencement du treizième siècle paraît le *Sachsenspiegel*. Au milieu du quatorzième, où le règne de l'ogive est à son apogée, l'Empereur Charles IV. donne la Bulle d'or. Au treizième siècle se terminent les Croisades qui mirent le Pape au dessus des pouvoirs temporels. Ces guerres saintes avaient fait prevaloir l'autorité de l'Evêque de Rome. Mais au treizième siècle l'activité des peuples Chrétiens avait prit une autre direction, et ils finirent par secouer toute espèce de domination." It is impossible, in passing the pontificate of Innocent III., to refrain from noticing that it was an epoch, in which such men appeared on the scene as St. Thomas Aquinas, St. Dominic, St. Francis of Assisi, John Gerson, author of the "Imitation of Jesus Christ," a composition that has been oftener printed than any other work; and in literature and the arts, about this period, are to be found the names of Dante, Robert de Lusarches, Arnolfo di Lapo, Erwin de Steinbach, besides a host of others.

Invested with all the character of chivalry and romance, and sacerdotal having yielded to secular art, the age seemed to express in matter its spiritual impressions. The aspiring vertical lines of its monuments have by some been considered types of aspiration after the Divinity. This may or may not have been the case, and there cannot but be an indisposition

to believe in symbolism, when there are so many forms in nature whose imitation, or the study whereof, would lead to the same results.

Architecture in the eleventh century was not even ranked among the liberal arts, which were but seven in number, as expressed in the subjoined hexameter line, those arts which were called servile being enumerated in the pentameter which follows it.

“Lingua, Tropus, Ratio, Numerus, Tonus, Angulus, Astra.  
Rus, Nemus, Arma, Faber, Vulnera, Lana, Rates.”

While the schools were limited in their instruction, and the Aristotelian philosophy was in its palmy state, the heavy Norman style, with its zig-zags, broken sticks, and dog's teeth, was the highest point the art could reach. Though the philosophy in question in some sort maintained its ground till the fourteenth century, it had been damaged previous to that period. Innocent III. issued a prohibition of the use of the physics and metaphysics of Aristotle, which, albeit not effectual, was nevertheless injurious to their growth. The universities, however, at a later period, did for the benefit of science and learning, what the association of Freemasons accomplished for pointed architecture at an earlier period. To these latter we are indebted, not only for the gigantic masses of exquisitely decorated composition, to be seen in the structures themselves which they erected, but for the amalgamation of them with the arts of painting and sculpture in the interiors.

From an early time the triangle seems to have been associated with as much mystery and veneration as the number 3. Without here touching on symbolism, in its use, whether equilateral or isosceles,—for the most important of the mysteries of the Christian religion will immediately occur to the reader, as respects the equilateral triangle,—we cannot but perceive, both in one and the other, a tendency to the production of the pointed arch. The geometrical law for describing it is, as every one knows, founded on the intersection of two circles of the same radius. The Pythagoreans called the equilateral triangle, Tritogeneia. It was, according to Plutarch, the symbol of justice. The subdivision of the arcs bounding an equilateral triangle by other arcs of equal radius, gives other modifications of the pointed arch, and by their intersections are obtained the skeleton lines of ornamented windows of an early period, which, at a later date, branched out into the most luxuriant forms. If we may depend on Cæsar Cæsarianus, the commentator on Vitruvius (1521), the equilateral triangle, which he applies on the cathedral of Milan, seems to have been as useful in its application to the general proportions of cathedrals as in the formation of the pointed arch. In applying it to Salisbury cathedral, the triangles on the section seem accurately to bound the dimensions used. There can, indeed, be no doubt that the heights, widths, and lengths of churches were greatly dependent on its repetition for their proportions; inasmuch as in most of the principal churches, when tested by it, the coincidence is too remarkable to be the result of accident. There were, however, other ingredients, and those of high importance, necessary to produce these noble edifices, to which we shall hereafter have occasion to allude. The same figure, the equilateral triangle was also of essential importance in governing the details of curves, wherein the subdivision 3 and its multiples were concerned.

Fig. 1.

Among other matters connected with the development of the art, Stieglitz, in 1834, brought to the notice of the public, the marks on courses of stone in many buildings in Germany, and elsewhere, called “masons' marks,” which by some have been supposed to be the personal marks of the masters of the works, but which are, in fact, nothing more than directions to the *setters*, and, indeed, are used by masons up to the present hour. Some of these, however, are curious in form and figure, and were most probably determined by the lodges. Their forms are principally rectangular, of forty-five degrees, of the equilateral triangle, of the intersection of horizontal and perpendicular lines, and circular. Some of them have so great a resemblance to Runic characters, that therefrom it has been argued the Anglo-Saxons taught the Germans architecture, and that they cultivated the art, and had masonic lodges among themselves, at a very early period; but this seems rather unreasonable; neither is it likely that the natives of this island were the chief artists employed on foreign cathedrals, though some may have been. That these marks, however, were used from some traditional knowledge can scarcely be doubted. Thus the mark , the cruciform hammer of Thor, is found in the minster at Båle, and repeated in the sixteenth century in the church at Oschatz. This mark abounds in a great variety of phases,—on medals, or annulets, in the museum of the Royal Academy of Copenhagen, and on many Runic monuments, as mentioned by Hobhouse, in his illustrations of *Childe Harold*. It is also found on the sacred jar of the Vaishnavas (*Asiatic Researches*, vol. viii.). At the Château de Coucy (13th century) is found , the Runic letter S. One mark of frequent recurrence is , an inverted Runic T. It may be seen at Fribourg, at the beautiful church of St. Catherine, Oppenheim, and at Strasburg, connected with the letter N. Without founding any hypothesis upon the singular agreement of these marks with the sixteen letters

of the Runic alphabet, it is at least a curious matter for further examination. These marks, it may be observed, are mostly found on the vertical faces of the masonry; but, as in present practice, they are also often found on the beds, or horizontal faces, where stones have been displaced. That they emanated from some central authority, and were universally understood by those who were subject to it, no doubt can exist, and their resemblance to the Runic characters seems to point to some Anglo-Saxon connection. This however is but conjecture.

Hobhouse, in the work above mentioned, states, that a character resembling the hammer of Thor is found in some Spanish inscriptions, and he seems to think it bears some affinity to *fig. 2*, which is often drawn by boys in Italy, though no meaning is ascribed to it; just as English shepherds, who never saw a coin of Antiochus, are in the habit of cutting the pentalpha on the turf.

The earliest lodge of which we have any authentic knowledge, was that of Strasburg. Of it, Erwin of Steinback seems to have been the head; he appears also to have been the first secular architect of importance that arose, and to have had privileges of great importance conceded to him by the emperor, Rodolph of Hapsburg. This lodge was regularly constituted, with power, round a certain extent of territory, to maintain order and obedience among the workmen under its jurisdiction. In 1278, Pope Nicholas III. granted to the body a bull of absolution, which was renewed by his successors up to the time, in the fourteenth century, when Benedict XII. occupied the papal chair. To Iodoque Dotzinger, master of the works at Strasburg in 1452, the merit seems attributable of so forming an alliance between the different lodges of Germany, as to induce a greater uniformity of practice. Whether from the central lodge of Strasburg, whence certainly branched lodges at Cologne, Vienna, and Zurich, branched also the lodges of France, England, and Italy, in which last named country, one existed at Orvieto, it is now perhaps too difficult a task to discover; but it is quite certain, from the majority of monuments in those countries, that in them all the constructive principles and the same proportions modified, were practised by the builders. While the architect was clerical, we observe the uniformity of the massive pillars, surmounted by the semicircular arch. In the thirteenth century, the lay architect appears, and the pointed arch becomes universal; the monuments of the latter period bearing so great a resemblance to each other, that no other probable cause can be assigned for their similarity, than the superintendence of some powerful association of operators. Allowance, however, must in many cases be made for the materials at hand in different localities, which, it is hardly necessary to observe, influence style in architecture.

In respect of what may be called the general form and character of the cathedrals and churches formed on the Byzantine models, which are derived from the ancient Basilica, it is well known the resemblance is close. In the principal features of the plan, the Byzantine and pointed cathedrals are the same. The choir is mostly found in the east, and is separated from the nave by transepts. Two towers with spires, at the west end, and a porch between, compose the principal façade. The nave rises above the side aisles. In the thirteenth century the choir, instead of being terminated circularly on the plan, became polygonal. It will be presently seen in what manner the number of sides of the polygon was regulated.

Among the more rational pieces of symbolism is that of the plan on which the earlier Christian churches were constructed, namely, the cross. At the beginning of the ninth century, in an inauguration (of a church) sermon, the preacher observes, "*In dextro cornu altaris quæ in modum crucis constructa est;*" and again, "*In medio ecclesiæ quæ est instar crucis constructa.*" (*Acta S. S. Benedict.*) After the tenth century it would perhaps be difficult to find a cathedral deviating from a cruciform plan. Round churches, as at Aix la Chapelle, Rieux, Merinville, and some few other places, are not enough in number to affect the rule. The Baptistery, which was a distinct and isolated building, and either circular or polygonal, does not here fall within our consideration.

It was in the thirteenth century that the termination of the choir of the Byzantine plan was changed, as we have just noticed, from a circular to a polygonal form. The general ordonnance of the plan was, however, not changed, and seems almost to have sprung from the laws and proportions upon which surfaces and solid bodies are dependent. The square and its diagonal, the cube and its sides, appear, at least the latter or the side of the former (see *fig. 3.*), to furnish the unit on which the system is based. Hence the numbers 3, 5, and 7, become the governing numbers of the different parts of the building. The

Fig. 2.

Fig. 3.

unit in the Latin cross, placed at the intersection of the nave, gives the development of a perfect cube, according to the rules of descriptive geometry. Here are found the number 3, in the arms of the cross and the centre square; the number 5, in the whole number of squares, omitting the central one; and the number 7, counting them in each direction. The foot, however, of the cross was, in time, lengthened to repetitions of five and six, and even more times. In monumental churches, formed on such a system, there necessarily arises an unity of a geometrical nature; and the geometrical principles emanating therefrom guided, not only their principal, but their secondary detail, as will after be seen. Even before the thirteenth century there seems to have been some relation between the number of bays into which the nave was longitudinally divided, and the exterior and interior divisions whereof the apsis consisted; but, after the introduction of the pointed style, this relation became so intimate, that from the number of sides of the apsis the number of bays in the nave may be always predicated, where the work has been carried out as it was originally designed. From the examination of many, indeed most, of the churches in Flanders, this circumstance had been long known to us; but for first publicly making it known, the antiquary is indebted, we believe, to M. Ramée (in 1843), whose work, as respects the German examples, has been of much service to us, and, moreover, extensively used: there are, however, many points on which M. Ramée does not enter into opinions similar to those we entertain. To resume, however: the connection of the bays of the nave with the terminating polygon of the choir was such, that the polygon is inscribed in a circle, whose diameter is the measuring unit of the nave, and generally of the transepts, and forms always the side of the square intercepted by them. It is most frequently octagonal (*fig. 4.*), and generally formed by three sides of the octagon. When this is used, the governing number will be found to be 8, or some multiple of it. Thus, in the Abbaye aux Hommes, at Caen (this, however, is previous to the thirteenth century), the termination of the choir is by a double octagon, and the number of bays in the nave is eight. The same occurs at St. Stephen's, Vienna, in the church of St. Catherine, at Oppenheim, at Lichfield cathedral, Tewkesbury abbey, and in almost every example that is known. It may be well here to observe, that the English cathedrals, from their great deficiency in symmetry, on account of their not having been finished on their original plans, do not afford that elucidation of the theory that is found in those on the Continent. In twenty-four instances of them we have sixteen in which the terminations are square instead of polygonal: when polygonal the rule seems to have been always followed.

An eastern termination of the choir in three bays may be produced from the octagon, by omitting the sides in the direction of the length of the building, as in *fig. 5.* In *fig. 6.*

Fig. 4.

Fig. 5.

Fig. 6.

the three sides will be found to be those of a hexagon; and in this case the number 6 governs the other parts. Examples of this arrangement are, the minster at Fribourg, in Brisgau; the cathedral at Cologne, where the apsis is dodecagonal, and there are six bays in the nave; and our own abbey at Westminster, where the eastern end is hexagonal, and there are found twelve bays in the nave.

In respect of nonagonal termination, the most extraordinary instance of a coincidence with the rules laid down by the governing lodges, occurs in the duomo of Milan, commenced at the end of the fourteenth century, and completed (the western front excepted) towards the end of the fifteenth century. However impure its details may appear to the rigid, it is nevertheless a monument of stupendous effect, and was doubtless the result of high refinement in the lodge which superintended its execution. Its apsis is formed by three sides of a nonagon, and the bays in the nave are nine in number. One third of the arc contained under the side of an equilateral triangle seems to be the governing dimension. The number 3, submultiple of 9, pervades the structure. There are three bays in the choir, and the like number in the transepts. The vault of the nave is subtended by an equilateral triangle. The lower principal windows are each designed in three bays. The plan of the columns in the nave in each quarter contains three principal subdivisions, and, in a transverse section of the nave, the voids are just one third of the solids. These are curious points, and, if Gothic architecture could ever again become the prevalent style of this country, much more worthy of investigation than the unimportant detail which now-a-days so much occupies the attention of archaeologists. If the stem of the plant is right, the leaves and fruit will be sure to grow into their proper forms.

*Figs. 7. and 8. show the decagonal terminations of an apsis. In the first, a side of the polygon faces the east; in the second, the angle of the polygon is on the axis of the church.*

Fig. 7.

Fig. 8.

The last case is of rare occurrence. Examples of it are, however, found in the church of Morienval, and in the choir of the dom-kirche of Naumburg. The first case is illustrated by a variety of examples, — such are Notre D<sup>me</sup> de Rheims, de Rouen, de Paris, dom of Magdeburg, Ulm, church of Ste. Elizabeth at Marpourg, the church of St. Quentin, &c., and, in this country, the cathedral of Peterborough; all of which have either five or ten bays in the nave.

The dodecagon, as a termination, is subject to the same observations as the hexagon: indeed they were anticipated by the mention of the cathedral at Cologne. The heptagon, however, and its double, have not been alluded to. Under this figure must be classed the magnificent cathedral of Amiens, wherein seven chapels radiate round the choir end, and as many bays in the nave. The choir at Beauvais is terminated by a double heptagon; and, had the church been completed, it would doubtless have had seven or fourteen bays in the nave. At Chartres, whose celebrated *clocher* forms, as the French saying goes, one of the requirements of a perfect cathedral, the choir is terminated by a double heptagon, and the nave contains seven bays. In the duomo at Florence, the eastern termination is octagonal, and there are four bays in the nave: this is an example of the expiring Gothic in Italy. It is much to be regretted that the piecemeal cathedrals of this country, though generally consisting of exquisite detail, do not, as has before been hinted, present examples upon which the great system of the Freemasons can be tested; neither do they afford means to investigate the dependence of the details, in respect of the multiple or submultiple of the polygon used in the apsis.

On an examination of the principal churches on the Continent, in and after the thirteenth century, it would appear that the practice of regulating the details was dependent on the number of sides in the apsis, or of bays in the nave. Thus, if the choir is terminated by three bays, formed on an octagonal plan, we find 3, or a multiple of it, is carried into the subdivision of the windows. So, if the number 5 is the dominant of the apsis, that number will be found transferred to the divisions of the windows; and in like manner the remainder is produced. In the finest examples on the Continent such will be found the prevalent arrangement. If it be attributable to any other cause than that suggested, let those who doubt point it out. The least that can be said of it is, that, if the facts be as stated, they point to a reliance on symmetry which, it is much to be regretted, has been entirely prætermitted in modern architecture, as now practised under the name of Gothic.

It may be proper to mention two or three other matters afflicting the extraordinary monuments of art erected in and after the thirteenth century. The aisles are usually half the width of the nave, though instances do occur where the width is equal. In some churches, previous to the twelfth century, the choir is found at the west end of the church. These were called *Eotholæ*, in contradistinction to the *Eopyle*, wherein the choir was in the east. Many churches also have two apsidæ, — such are the cathedrals at Nevers and at St. Cyr, and in Germany St. Sebald, Nuremberg; the dom-kirche at Mayence, the abbey church at Laach, the cathedrals of Bamberg, Worms, and others.

It will not be difficult to anticipate, by what has already dropped from us, that we hold symbolism in churches an idle conceit, and that not much will be said by us on that subject; but a few specimens of the nonsense it induces may as well be set down. The venerable Bede, for instance, says that the walls of a church are a symbol of the Christian worshippers that frequent the edifice. "*Omnes parietes templi per circuitum omnes sanctæ ecclesiæ populi sunt, quibus super fundamentum Christi locatis, ambitum orbis replevit.*" The venerable scribe, be it observed, is speaking of Solomon's temple. Again, in respect of doors, we have "*Ostium autem templi Dominus est, quia nemo venit ad Patrem nisi per illum,*" &c. As to the windows, they are symbols of the saints and spiritual worshippers; "*Fenestræ templi sunt sancti et spirituales.*" To come, however, to recent symbolism. We find that the moderns have discovered that the principal entrance of a church is a symbol of our entrance into physical and moral life; that the tympan, or gable-like form, over the great western porch (whose origin is the Greek pediment, but raised to conform with the character of the style), is a symbol of the Holy Trinity; the great rose window at the western end of a church is, from its circular form, accounted a symbol of Divine Providence! At Amiens, the four rose windows have been considered symbolical of the four elements! In respect of the towers, too, they are not without *their* meaning: that on the left is a symbol, at least so it is said, of the ecclesiastical and spiritual hierarchy, and that

to the right represents order, that is, the civil or temporal power! and generally, where four horizontal divisions occur, the lower one is symbolical of the curé, the next upwards of the dean or archdeacon, the third of the bishop, and the fourth of the archbishop. Should a fifth horizontal division occur, the primate is the type. So in the right hand tower, the lowest compartment represents the mayor, and in succession upwards appear a count, a duke, a king; and if the tower be covered with a spire, no less than an emperor appears. One is almost surprised that there is no symbol to represent the *suisse* of the continental, nor the beadle of our churches in this country.

The interior of a church, according to the symbolists, affords some further curious features of mysticism. The principal entrance is at the *foot* of the Cross, because, by the use of the FEET (i.e. travelling) the Gospel was preached! What is called *canting* heraldry surely does not equal this. The nave is said to represent the body of the faithful! The ceiling over the altar is accounted a symbol of heaven, and the chapels round the altar are said to represent the *aureola* round the head of Christ! But it is scarcely worth while to waste more time on the consideration of such absurdity, where the things have been ingeniously fitted to the types, instead of the converse. There is, however, one other point connected with the subject, which has been recently revived, and a few words must be expended in notice of it.

If on the diameter of a circle (*fig. 9.*), with an axis perpendicular to it, an equilateral triangle be described, whose vertical height shall be equal to the semi-diameter of such circle, and from the angles of the triangle on the diameter, with a radius equal to one side of the triangle, arcs of circles be described cutting each other superiorly and inferiorly, the figure described is that which is called the *Vesica Piscis*, or Fish's Bladder. This figure has been very cleverly adapted, first by Mr. Kerich, and since by others, to the plans of Gothic edifices, so as to make the one fit the other. Now, there is scarcely a regular geometrical figure which might not be coaxed into such an arrangement, hence it is worth while to examine the subject; but a slight investigation of this part of a fish's body will be sufficient, we trust, to set the matter at rest.

Fig. 9.

To the bladders of a large number of different sorts of fish examined by us, the figure in question has little or no resemblance. Its use to this class of animals is yet, among naturalists, unsettled. It is the *vesica natatoria* of Willoughby, and the *vesica aerea* of Artdi. In this country it is called the sound, or swim. Situate in the anterior part of the abdominal cavity, it adheres to the spine. In some fishes it is altogether wanting, and its shape varies in different fishes. In the herring and some others it is oblong, and pointed at both ends, and would tolerably suit the theory of the writers who proportion churches by it; but in the salmon it is obtuse at both ends. In the burbot it is obtuse at the lower end, and bifid at its superior extremity. In the carp it is divided transversely. *Utrum horum?* or have the symbolists procured a conventional fish for their purpose. If the general shape of a fish, a carp or bream for instance, were selected for their theory, we should be much nearer the form sought, and better able to connect it with the subject, for there is no doubt that the figure was held in great veneration by religionists, and, for aught we know, with justice.

The Greek word *ἰχθῦς*, signifying a fish, seems to have been in early ages a mystical word, under which Christ was denominated, "Eò quod in hujus mortalitatis abyssò, velut in aquarum profunditate, sine peccato esse potuerit, quemadmodum nihil salsedinis a marinis aquis pisci affricatur;" that is, Because in the unfathomed deep of this mortal life he could exist without sin, even as a fish in the depths of the sea is not affected by its saltness. The term, too, at a very early period furnished an anagram, whose parts were expanded into the expression *Ἰησοῦς Χριστὸς Θεοῦ υἱὸς Σωτὴρ*. The initials of these words were, in their turn, expanded into a long acrostic (to which reference may be had, *sub voce* *Acrostichia*, and also under the term *Ichthys*, in Hoffmann's incomparable Lexicon) on the Day of Judgment, said to have been delivered, *divino afflatu*, by the Erythrean sybil, but much more resembling the hard-spun verses of a learned and laborious man than the extemporaneous effusions of a mad woman. This acrostic is recognised by Eusebius, and by St. Augustine (*Civ. Dei.*) &c. Notwithstanding the sanctity with which the monogram is invested, as well as all that has been written on the subject, there is nothing connected with it to afford proof of its connection with the form and plan of the churches erected under the lodges of Freemasons at any period of the art. Indeed there are so many more scientific and reasonable grounds for the system on which they wrought than that just alluded to, that it is only necessary to dismiss it from further consideration by stating, that, if tested by the finest and most perfect of the cathedrals on the Continent, the impossibility of making it fit will soon be apparent. Apology perhaps, therefore, would be due for so long a digression upon it, had it not been for an adverse opinion recently published by a gentleman (C. R. Cockerell), whose talents and learning deservedly rank high in the eyes of the public, and for whom every one must entertain the highest respect and esteem. — (*See Pamphlet on the Archi-*

tectural works of William of Wykeham, read, 1845, before the Archæological Institute of Great Britain and Ireland, at their annual meeting.)

As the perpendicularity of style changed, at the beginning of the thirteenth century, from that which might be termed horizontal, so did the comparatively rude and clumsy form of its ornament assume a lightness founded on a close observation of nature. Its sculpture is endowed with life, and its aspiring forms are closely connected with the general outlines bounding the masses. The models used for decoration are selected from the forest and the meadow. These, however, though closely and beautifully imitated (says Ramée), are submitted to reduction within such boundaries as brought them to a regular and geometrical form. Thus is found every conceivable description of ornament brought within the limits of circles, squares, and triangles, as well as within the more varied forms of the many-sided polygons; the latter, as in the marigold and rose windows, being again subject to the circumscribing circle: these polygonal subdivisions having always reference to the regulating subdivisions of the apsis hereinbefore mentioned.

The circle obviously presents a boundary for a very extended range of objects in nature. In the vegetable world, a flower is scarcely to be found which, within it, cannot be symmetrically arranged. Its relations afford measures for its subdivisions into two, three, four, and six parts, and their multiples, by the diameter and radius alone; the last being an unit, upon which the equilateral triangle and hexagon are based: moreover, as the interior angles of every right-lined figure (*Euc. prop. 32. b. 1.*), together with four right angles, are equal to twice as many right angles as the figure has sides, it will be immediately seen that the interior angles in the equilateral triangle, the pentagon, the hexagon, the nonagon, and the dodecagon, are divisible by the sides so as to clear the result of fractions. Thus, in the equilateral triangle, the number of degrees subtended by the sides is  $60^\circ$ . In the pentagon the number is  $108^\circ$ ; in the hexagon,  $120^\circ$ ; in the nonagon,  $140^\circ$ ; and in the dodecagon,  $150^\circ$ . Independent, therefore, of the service of the circle in construction, we are not to be surprised at its being so favourite a figure in architecture, from the period at which the art was to become truly serviceable to mankind.

In respect of the pentagon (*fig. 12.*), if lines be drawn from each angle so as to connect every two of its sides, the pentalfa results; a figure in much esteem in the thirteenth and fourteenth centuries, and used among the Pythagoreans, as a symbol of health, centuries and centuries before.

The heptagon and undecagon, whose interior angles are not divisible without a fraction or remainder, were rarely used by the Freemasons, an instance of either does not occur to us.

An inspection of *figs. 10. to 16.* will show the mode of generating from the several polygons the lobes of circular windows, as also the way of obtaining the centres for the lobes in a simple and symmetrical manner. In *fig. 10.* the basis of formation is the equila-

Fig. 10.

Fig. 11.

Fig. 12.

Fig. 13.

teral triangle, and three lobes are the result. Those of four lobes, or quatrefoils (*fig. 11.*), originate from the square; and the Cruciferae, or cruciform plants, Tetradymania of Linnæus's system, seem to be their types in nature.

For those of five lobes, resulting from the pentagon (*fig. 12.*), types are found in the Pentandria, Decandria, and Icosandria classes of Linnæus. They comprise the rose, the apple, cherry, and medlar blossoms; those of the strawberry, the myrtle, and many others.

For circular windows consisting of six lobes, and based on the hexagonal formation (*fig. 13.*), the Hexandria class seems to furnish the type, under which are found almost all the bulbous-rooted flowers, pinks, &c. These observations might be extended to a great length; but the writer does not feel inclined to pursue the system to the extent to which it has been carried by a German author (Metzger), who bases the principles of all pointed architecture on the formations of the mineral and vegetable kingdoms. In *fig. 14.*

Fig 14.

Fig. 15.

the octagon is the base; in *fig. 15.* the nonagon; and in *fig. 16.* the dodecagon. Beyond the last, the subdivision is rarely carried. It was not that all these types were selected from a mere desire of assimilating to nature the decorations of the thirteenth century, but it sprang from that deep impression of the utility of geometrical arrangement, which sought in the vegetable kingdom, and elsewhere, such forms as fell in with the outlines adopted.

Among the flowers used for the angular decorations of pinnacles and spires, on crockets, and in similar situations, an ornament very much resembling the *Cypripedium calceolus*, or lady's slipper, and the iris, are of constant occurrence. The length, however, to which we might pursue the subject, warns us to refrain from further remarks on these matters, and to proceed to a short consideration of one much more important, and much less attended to in the present day, if indeed at all thought of.

On the horizontal section or plan of a building, the solid parts cut through at their bases are, it is well known, called its points of support, because on them rests the whole mass of materials of the edifice (see sect. 2848.). It is manifest, that as these points are diminished in area, in respect of the mass, so is a greater degree of skill exhibited in the work. From the table in the following page it will be seen that, in seventeen celebrated edifices, the ratio of their points of support to their whole areas varies from .116 to .238, nearly double. It is curious to observe the high rank borne in this table by Henry VII.'s chapel: generally, skill seems to have increased with greater experience.

Led by Le Brun (*Théorie de l'Architecture*, &c. fol. Paris, 1807.), we were many years ago, as previously stated in this work, induced to inquire into the doctrine of voids and solids in the Greek and Roman temples, and though we soon discovered that that author had committed manifest errors in his mode of applying his theory, there could be no doubt that if its principles were properly carried out, they would coincide with the best examples both ancient and modern. In a small work by the writer (London, 8vo. 1837), entitled *Elements of Architectural Criticism*, the subject was first brought before the English public; it was again considered in a paper read before the Institute of British Architects at an early period of its establishment; and subsequently, in the *Encyclopedia of Architecture* (1842), the investigation was extended to some length, but no application nor examination of it was entered into as connected with the Byzantine and pointed styles. The study we have subsequently bestowed upon it has not, we regret, from various pressing occupations, received from us all the attention necessary to reduce the examples within such

Fig. 16.

bounds as to make the matter subject to certain laws, though we think an approximation has been effected towards it.

It is greatly to be lamented that, among the many and able writers on Gothic architecture, details more than principles seem to have occupied their minds. The origin of the pointed arch seems to have entirely absorbed the attention of a large proportion of them, whilst others have been mainly content with discussions on the peculiarities of style at the different periods, and watching with anxiety the periods of transition from one to another.

Foliage, mouldings, and the like, have had charms for others; all, however, have neglected to bestow a thought upon the grand system of equilibrium by which such stupendous edifices were poised, and out of which system a key is to be extracted to the detail that enters into them. It is, however, to be hoped that abler hands than ours will henceforth be stimulated to the work, such being abundant in the profession whereof we place ourselves as the humblest of its members.

As on the horizontal projection or plan of a building, the ratio of the points of support have been above considered, so in the vertical projection or section of a building may the ratio of the solids to the voids be compared, as well as the ratio of the solids to the whole area. In *fig. 17.* the shaded parts represent the solids, which therefore give boundaries of the voids. Worcester Cathedral is the example shown. In this mode of viewing a structure, as also in that of the points of support, there is a minimum to which art is confined, and in both cases for obvious reasons there are some dependent on the nature of the materials, and others on the laws of statics. Though there may be found some exceptions to the enunciation as a general rule, it may be safely assumed, that in those buildings, as in the case of the points of support, wherein the ratios of the solids to the voids in section are the least, the art not only as respects construction, but also in point of magnificence in effect, is most advantageously displayed. In every edifice like a cathedral, the greater the

Fig. 17.

space over which the eye can range, whether horizontally or vertically, the more imposing is its effect on the spectator, provided the solids be not so lessened as to induce a sensation of danger.

In the subjoined table, which, with the exception of Nôtre Dame de Paris, contains the same buildings as those already cited, it will be seen that the ratios of the solids to the voids varies from  $\cdot472$  to  $1\cdot118$ , a little less than half to a little more than a whole. But if in their sections we compare the ratios of the solids to the whole area, there results a set of numbers varying from  $\cdot321$  to  $\cdot528$ , and that nearly following the order of the ratios of the points of support.

Though the coincidence between the ratios of increase, in the points of support, does not run quite concurrently with the ratios of the solids and the areas in comparing the cathedrals of the different centuries, yet sufficient appears to show an intimate connection between them. Where the discrepancy occurs, the points of support seem inversely set out. Such, for instance, will be seen in Ely Cathedral, wherein, though the ratio of the solids to the voids in section is as high as 1 (or ratio of equality), that of the points of support is as low as 0·182, so that the space, or airiness, which is lost in the former, is compensated by the latter. Generally speaking, however, the points of support diminish as the ornament of the style increases. Thus, in Norwich Cathedral (the nave), of the early part of the twelfth century, the ratio of the points of support is 0·238, that of the solids to the voids being 0·603; while at Salisbury (latter part of the thirteenth century) the ratio of the points of support is only 0·190, and that of the solids to the voids, 0·472.

From the foregoing examination, there can scarcely exist a doubt that the first and leading lines of these fabrics were based upon a geometrical calculation of extremely simple nature, but most rigidly adhered to. Thus, taking a single bay in the nave, say, from centre to centre, and ascertaining the area, that has only to be multiplied by the ratio, to give the superficies necessary for the points of support, which, as the tables indicate, were diminished as experience taught they might be. These matters then being adjusted, and falling as they might, the system of ornamentation was applied altogether subsidiary to the great and paramount consideration of stability.

A very ingenious writer and skilful architect (Mr. Geo. Ware), some years ago, took great trouble to deduce the stability of the buildings in question, from the general mass of the walls and vaulting containing within them some hidden catenarian curve. If such were the case, which can hardly be admitted, in as much as a chain for such purpose might be made to hang in all of them, it is quite certain this property was unknown to those who erected them. Dr. Hook was the first who gave the hint that the figure of a flexible cord, or chain, suspended from two points, was a proper form for an arch.

## SECT. II.

## DIFFERENT PERIODS OF THE ART, AND FLAMBOYANT STYLE.

The division we have used in a former part of the work (pages 169. to 195.) of the different styles of Gothic, may be usefully compared with those in France at the same respective periods; and using the small work of M. Caumont for that purpose, the following table results, in which the styles are set down as designated by that writer.

The Romanesque 996 to 1150	{ A. D. 1000 1100	{ Anglo-Saxon 970 to 1066 Norman 1066 to 1190
Primary Gothic 1150 to 1250	{ 1200	{ Early English (Lancet) 1190 to 1300
Secondary (Rayonnant) 1250 to 1400	{ 1300	{ Ornamented English 1300 to 1460
Tertiary (Flamboyant) 1400 to 1500	{ 1400 1500	{ Florid English or Tudor 1460 to 1537

The Comité des Arts adopted a classification somewhat different to the above, viz.

Latin Style. From the fifth to the eleventh century.

Roman Style. Eleventh and twelfth centuries.

Gothic Style. { Primary, or lancet, thirteenth century.  
Secondary, or radiating, fourteenth century.  
Tertiary, or flamboyant, fifteenth and early part of sixteenth century.

For the *château*, M. de Caumont has proposed the classification subjoined.

1st class. Fifth to tenth century : Primitive Roman.

2nd „ Tenth and eleventh centuries : First secondary.

3rd „ End of eleventh and twelfth century : First tertiary.

4th „ Thirteenth century : Primitive pointed.

5th „ Fourteenth and first half of fifteenth century : Secondary and tertiary pointed.

6th „ Second half of fifteenth and sixteenth century : Quaternary pointed.

These variations of nomenclature are an evil much to be regretted, and are not likely to be cured until some able man appear to re-christen the whole detail satisfactorily—He has not yet appeared.

Of the Tertiary French style, or the Flamboyant, some points demand attention. Full as it is of rich detail, and in that respect concurrent with the florid English, or Tudor style, yet there is vast difference between the two. The best example of it in this country—and there are but few—is in Dorchester church, Oxon. In France examples of it abound. It received its name from M. Auguste Le Prevost, and the appellation has been adopted by the English antiquaries. One of its chief features is the divergence of the mullions into flowing wavy lines resembling flame. Perhaps the finest specimen of this style is in the Cathedral at Evreux, whose north transept and spire are extraordinary works. In the *fig. 18.* we place before the reader one of the compartments of the sacristy of the church at Caudebec, which conveys a fair notion of the peculiarity of the style. It must be admitted that it is characterised by an excess and overcharge of ornament almost amounting to the capricious. The foliage of the forest and the vineyard is changed for colewort and the thistle. The sculpture becomes inflated, and, compared with the previous age, almost borders on vulgarity. The profiles are complex, and refined disorder seems to overpower the detail. As to repose, it is no where to be found, and the imagination of the artists who practised it seems to have exhausted itself in the tortuous, twisted, and laboured parts where of it is composed. Further it seems impossible to have advanced. It was to the Gothic, what the Borrominesque was to Italian architecture; and the introduction of the style known by the name of the Renaissance closed its career. Notwithstanding its faults, one cannot refrain from admiration of it. Besides the cathedral at Evreux, we may mention the examples of Nôtre-Dame de St. Lo, St. Vincent at Rouen, some parts of St. Jacques at Dieppe, St. Jean at Caen, St. Pierre at Senlis, St. Catherine at Honfleurs, the north porch at Beauvais, St.

Fig. 18.

Severin, St. Méry, St. Germain l'Auxerrois, and St. Gervais at Paris, the choir and transepts of St. Remi at Rheims, the upper part of the north tower and spire of the cathedral at Chartres, &c. Of it, however, much more will hereafter be said.

Among the characteristics of the Flamboyant style, is that which Mr. Willis of Cambridge calls, in a most ingenious and valuable paper, read before the Institute of British Architects, *penetration or interpenetration* of the different mouldings and parts. The French antiquaries have called the system in question *moultures prismatiques*. Neither of these terms seem satisfactory, but of the two we are inclined to prefer the first as most significant. We will here illustrate the subject by some examples. Mr. Willis, in the paper above mentioned, observes that the practice is very rarely to be seen in English buildings; he, however, produces an instance of it in the turrets of King's College chapel, at Cambridge (see fig. 19.), where the cornice A of the pedestal seems to pierce the plinths of the angle

FIG. 19.

FIG. 20.

buttresses, and appears at B. This appears, however, to be by no means a capricious, but rather an indispensable arrangement, by which the solidity of the octangular base was obtained without the necessity of the multitude of re-entering angular mouldings, which would have otherwise been carried round the buttresses.

The instances, however, of interpenetration are abundant in France. Amongst those selected by Mr. W. is one from a screen in the cathedral at Chartres; it is given here geometrically, instead of in perspective, as by that gentleman (see fig. 20.). The last example we shall produce is from the stone cross at Rouen (see fig. 21.), in which the interpenetration principle is displayed in many of the vertical as well as horizontal members of the structure. (See the parts marked A A where the fillet of the mullion pierces the chamfered and moulded parts of the sill.) "In many Flamboyant examples," says Mr. Willis, "small knobs and projections may be observed, and on a superficial view might pass for mere unmeaning ornaments, but will be found explicable upon this system of interpenetration." Fig. 22. "is a window (from a house near Roanne), at the base of whose mullions knobs may be observed, which really represent the Gothic base of a square mullion on the same plinth with the hollow chamfered mullion and interpenetrating with it."

Mr. Willis observes, "it may perhaps be found that this character belongs to one period, or one district, of the Flamboyant style;" but from our own observation, we are inclined to believe it to have been

FIG. 21.

FIG. 22.

universal from the middle of the fifteenth century, to the period when the style of the Renaissance superseded it. The principles on which it is conducted certainly prevailed in Germany and in the Low Countries, as Mr. W. afterwards states. A notion to what extent

Fig. 23.

it proceeded may be perceived by *fig. 23.*, above, which is from Möller's *Denkmäcker der Deutschen Baukunst*, and exhibits on the plan a series of interferences contrived with great ingenuity and a consummate acquaintance with practical geometry. The subject is the plan of a tabernacle, or canopy, such as is not unfrequent in churches on the Continent. It shows, says Möller, how the simple and severe architecture of the thirteenth and fourteenth centuries had been debased.

### SECT. III.

#### PENDENTS.

A striking feature of the Flamboyant style is the frequent use of pendants in the vaulted roofs of the period. These, however, are not confined to France or the Continent generally: the Tudor period in this country exhibits many splendid instances of their employment, none, perhaps, more gorgeous, or more interesting as regards its construction, than the

Chapel of Henry the Seventh. It is not our intention here to enter into the details of the various examples that exist. Some of them have been beautifully and scientifically investigated by Mr. Willis, the gentleman above quoted, in his paper to the Institute of Architects, on the construction of the vaults of the Middle Ages. That paper we earnestly recommend for perusal to every one who wishes to be intimately acquainted with the subject, and we therefore now proceed merely to indicate the principles upon which the fairy-like system of not only suspending vast bosses from the ceiling was conducted, but that by which these bosses or pendants became in their turn the springers for supporting other vaults, as in the beautiful little Lady Chapel at Caudebec in Normandy, and many other examples. The chapel in question is hexagonal on the plan, about 23 feet in span, or from side to side; and *fig. 24.* shows the mode by which, from the key-stone of an arch approaching

FIG. 24.

a semicircular form, and suspended or elongated beyond its ordinary depth, support is given for the springing of the vaults of the different bays. On this practice Philibert Delorme observes, "*Les ouvriers ne font seulement une clef au droit de la croisée d'ogives, mais aussi plusieurs quand ils veulent rendre plus riches leurs voutes, comme aux clefs où s'assemblent les tiercerons et liernes, et lieux où ils ont mis quelquefois des rempans, qui vont d'une branche à l'autre, et tombent sur les clefs suspendues, les unes étant circulaire, les autres en façon de soufflet avec des guymberges, mouchettes, claire-voyes, feuillages, crestes de choux et plusieurs bestions et animaux : qui étoient trouvés fort beaux du temps qu'on faisoit telles sortes des voutes, pour lors appellées des ouvriers (ainsi que nous avons dict) voutes à la mode française.*"

We have just above shown the mode of suspending the pendent in a polygonal building. The *fig. 25.*, on the following page, by a little consideration, will explain the mode of suspending pendants not centrally situate, as in the case of the ceiling of Henry the Seventh's Chapel, whose date runs coincident with the Flamboyant period. The figure is a transverse section and plans of the vaulting of the building, in which one of the main arches, on which the whole construction depends, springs just below A, and reaches its summit at B. The voussoirs or arch stones whereof it consists are marked in their order. The dotted interval from *a* to *b* is not to be considered as an interruption of the formation of the arch by the pendant, but may be supposed an imaginary line passing through it, or rather through the arch stone or voussoir C, whose general form is marked by the bounding letters *c d e f b a*; so that, in fact, the pendent is nothing more, as in the case of the Caudebec Lady Chapel, than a voussoir, a large part whereof hangs down below the face of the vaulting. The voussoirs are out of blocks about 3 feet 6 inches deep; but a considerable portion of the solid below the soffit of the arch is cut away to form the lobes of the cinquefoils. The arch D serves, by its connection with the walls, to stiffen and give weight to the arch where it would be most required, that is, towards the springing. The pendent or voussoir E, on the same block with C, being thus established in its place, serves at, or towards its foot, as a springer for the ribs of a fanwork tracery shown on the plan, whose ribs are, in fact, ribs of a dome, and in construction do not differ from it. Their section is shadowed somewhat lighter than the pendent voussoir. The fanwork round each affords the means of introducing another pendent at its meeting at F in the plan. The fan vault is very properly distinguished by Mr. Willis from what he calls the *stellar vault*, which is formed of ribs that may be, and indeed frequently are, of different curvature, and the rays of the star of different lengths; whereas the fan vault consists of ribs of the same curvature and height, and the summit of the fan is bounded (see the *fig.*) by a horizontal circular rib, instead of the ends of lozenges forming the points of the star. "The effect of the fan is that of a solid of revolu-

Fig. 25.

tion, upon whose surface panels are sunk: the effect of the star is that of a group of branching ribs." It is manifest that the constructive details of these two sorts of vaulting are vastly different. In the one, the dependence is upon ribs which support, by rebates on them, the filling-in panels; while, in the other, the principle is similar to that of dome-vaulting. This will be immediately perceived by reference to the plan G, in which the courses are marked, as also in the part of the section marked H. The plan I. shows the tracery of the soffite of the vault. The author above quoted observes, "The construction of these fan vaults is in all examples so nearly the same, that they seem to have proceeded from the same workshop; and it is remarkable that, at least as far as I know, there are no Continental examples of them; whereas, of the previous vaults, there are quite as many on the Continent as in England. In France, indeed, the *lierne*" (ribbed) "vaults are not very numerous; they are confined to small chapels, and their patterns are in general simple. But in Germany and in the Netherlands there is an abundance of them, distinguished, certainly, from ours by local peculiarities, but nevertheless of similar mechanical construction, and requiring the same geometrical methods."

The introduction of fan vaulting seems to have occurred in the beginning of the fifteenth century. The first instance wherein the span was considerable is the Dean's Chapel attached to the north-west transept of Canterbury cathedral. In St. George's Chapel at Windsor, the aisles and central compartment only have fan vaults, the principal vault not being fanwork. The chief works of this kind, of known date (about 1500), are

Henry the Seventh's Chapel at Westminster, King's College Chapel at Cambridge, the central tower of Canterbury, and Bath Abbey Church.

We must to the above add mention of the church of St. Etienne du Mont at Paris, in which we find a remarkable example of the style of the Renaissance contending with the expiring Flamboyant style. In short, the whole of the interior is a mass of interesting incongruities. The church is cruciform, and at the intersection of the cross is a pendent keystone, most elaborately wrought, and more than 13 feet deep. It is obvious, in respect of these pendants, that there is no mechanical difference between their pendency and their being insistent, as lanterns are, on domes.

## SECT. IV.

## VAULTING.

The method of covering a space by vaulting with cylindrical arches, in its various modes, has been already described in the body of this work. (See 1443. *et seq.*) We here, therefore, have thought it proper to enter into a view of the general forms of groining in pointed architecture, observing, by the way, that the groins at the arrises, up to the twelfth century, were seldom moulded with more than a simple torus or some fillets. In the twelfth century, however, the torus is doubled, and the doubling parted by a fillet. Towards the end of the twelfth century, three tori often occur; and at the beginning of the thirteenth, the moulded arrises become similar to the moulded archivolts of the arches both in their form and arrangement. In France, until the middle of the fifteenth century, the arrises of the groins only were moulded; but in this country the practice took place much earlier, for, instead of simple groining, the introduction of a number of subdivisions in the soffits of arches had become common. In *fig. 26.* is given a plan of the soffit of a vault of this kind, in which A is an *arc doubleau* (by which is understood an arc supposit below another at certain intervals, and concentric with the latter); B is an upper arch, called by the French antiquaries *formeret*; C, the wall arch, or *formeret du mur*; D is a diagonal rib, or *croisée d'ogive*; E, intermediate rib or *tierceron*; FF, summit ribs or *liernes*; G, the key or boss, *clef de route*. Mr. Willis has used the French terms here given, and as we have no simple terms to express them in English, it may be convenient to adopt the practice.

In Gothic edifices the ribs formed by the intersections of the groins perform the office of supporting the vaulting which lies upon them, they in their turn being borne by the pillars. Thus, in the simple groin (*fig. 27.*), the arches or ribs AA, and diagonal rib C, carry the vaulting BB, a rebate being formed at the lower part of the ribs on which the vaulting lies. This figure exhibits the simplest form of groining in any species of vaulting, the intersecting arches being of equal height. The contrivance in its earliest state was ingenious, and the study attractive, and we cannot be surprised at Dr. Robison observing, in respect of the artists of the thirteenth and two following centuries, that "an art so multifarious, and so much out of the road of ordinary thought, could not but become an object of fond study to the architects most eminent for ingenuity and invention: becoming thus the dupes of their own ingenuity, they were fond of displaying it where not necessary."

Fig. 26.

Fig. 27.

This observation would be fully verified had we room for showing the reader the infinite number of devices that ingenuity has created: he will, however, from the few elementary ones that we do give, be enabled to see the germs of countless others.

Ware, in his *Tracts on Vaults and Bridges* (London, 1822),—a work which, notwithstanding the quaint method in which the subject is treated, contains extremely valuable matter,—has made some remarks which we must introduce at length, or justice would not be done to them. “In the vaulting,” he says, “of the aisles of Durham and Canterbury cathedrals are to be observed the *arcs doubleaux* and groined ribs in round-headed vaults. In the naves of the same buildings is the same character of vaulting, except that the arch of the vault is pointed. Some vaults of this kind are to be distinguished from others by the positing of the stones of the vault between the ribs, which, instead of being parallel to each side of the plan, as in Roman groined vaults, take a mean direction between the groined rib and the ribs of the arches over the sides; whence they meet at the vertex at an acute angle, and are received by stones running along the vertex, cut in the form of a ratchet. The advantage of this method consists in requiring less centering, and originates in the position of the ribs at the springing.” “From these beginnings vaulting began to assume those practical advantages which the joint adaptation of the pointed arch and ribs was calculated to produce.” “The second step differed from the first, inasmuch as at the vertex of the vault a continued keystone or ridge projects below the surface of the vault, and forms a feature similar to the ribs. But here it was necessary that the ridge should be a stone of great length, or having artificially that property, because its suspension by a thinner vault than itself would be unsafe, unless assisted by the rib arches over the diagonals and side, a distance equal to half the width of the vault. To obviate this objection, other ribs were introduced at intervals, which may be conceived to be groined ribs over various oblongs, one side continually decreasing. This practice had a further advantage, as the panels or vaults between the ribs might become proportionally thinner as the principal supports increased. It is now that the apparent magic hardness of pointed vaulting and the high embowered roof began to display itself; from slender columns to stretch shades as broad as those of the oak’s thick branches, and, in the levity of the panel to the rib, to imitate that of the leaf to the branch.” “On comparing rib-pointed vaulting with Roman vaulting, it will be invariably found, that the rib itself is thinner than the uniform thickness of the Roman vault under similar circumstances; and that the panel, which is the principal part of the vault in superficial quantity, sometimes does not exceed one ninth part of the rib in thickness. The Gothic architects, it has been expressively said, have given to stone an apparent flexibility equal to the most ductile metals, and have made it forget its nature, weaving it from its fondness to descend to the centre.”

In the second example (*fig. 28.*), another rib, *ab*, is introduced, which on the plan pro-

Fig. 28.

Fig. 29.

duces the form of a star of four points. The forms of these thus inserted ribs result from curves of the lines on the plan in the space to be vaulted. As many radii are drawn from the angles of the plan as there are ribs intended, until they mutually intersect each other. The curvatures of the ribs will be elongated as they recede from the primitive arch, till they reach the centre on the place where the groins cross, and where of course the elongated curve is a maximum. The ribs thus form, when they are of the same curvature, portions of an inverted conoid.

In the next example (*fig. 29.*) the primitive arches are unequal in height, the arch *A* being higher than the arch *B*. The plan remains the same as in that immediately preceding; but from the inequality of height, *a d*, *c b*, must be joined by curved lines, determined on one side by the point *a*, where *e a* intersects the longer arch. A curved summit rib, as

well longitudinally as transversely, may occur with equal or unequal heights of primitive arches, as in *fig. 30.*; but the stellar form on the plan still remains, though differently

Fig. 30.

Fig. 31.

modified, with the same, or a less or greater, number of ribs on the plan (*fig. 31.*). By truncating, as it were, the summit ribs level or otherwise with the tops of the primitive arches, and introducing on the plan a polygon or a circle touching quadrants inscribed in the square, we obtain, by means of the rising conoidal quadrants, figures which perform the office of a key-stone. In this, as we have above observed, the construction of the work is totally different from rib vaulting, inasmuch as each course, in rising, supports the next, after the manner of a dome, and is not dependent on ribs for carrying the filling-in pieces. Hence the distinction between fanwork and radiating rib work so judiciously made by Mr. Willis.

The sixth example (*fig. 32.*) is with primitive arches of different heights. It is an irregular star on its plan, that is to say, the points are of different angles. From the figure it will scarcely need explanation, after what has been already said in relation to the subject.

A polygonal space may be vaulted in three different ways. First, by a column in its centre, which serves for the reception of the ribs of the vault, the column or pillar performing in such case the office of a wall, as in the chapter-houses of Worcester, Salisbury, Wells, and Lincoln. This mode evidently

Fig. 32.

admits of the largest space being covered on account of the subdivision of the whole area by means of the central pillar. The second mode is by a pendent impost for the reception of the arches, as in the case of the Lady Chapel at Caudebec above given. This mode is necessarily restricted in practice to small spans, on account of the limits attached to the power of materials; albeit in theory its range is as extensive as the last. The last method is by at once vaulting the space from wall to wall, as in *fig. 33.*, which is like the vaulting to the

Fig. 33.

Fig. 34.

kitchen of the monastery of Durham Cathedral, or the *fig. 34.*, similar to the chapter-house at York, of which, the upper part being of wood, Ware quaintly observes, "The people of

Yorkshire fondly admire and justly boast of their cathedral and chapter-house. The principle of vaulting at the chapter-house may be admired and imagined in stone; not so the vault of the nave; it is manifestly one of those sham productions which cheat where there is no merit in deceiving." The principle, as Ware justly observes, is perfectly masonic, and might be easily carried out with stone ribs and panel stones, it being nothing more than an extension of that exhibited in the third example of simple groining (*fig. 27.*) above given; and the same remark applies to the Durham kitchen.

Some observations must be offered to explain the nature of the vaulting at King's College Chapel at Cambridge, and the silly story related by Walpole of Sir Christopher Wren, saying, "that if any man would show him where to place the first stone he would engage to build another" (chapel like it). The vault of the chapel in question is divided into oblong severies, whose shorter sides are placed longitudinally (*fig. 35.*). It is, therefore, evident that the curves of the inverted quadrants must intersect each other previous to the whole quadrant of the circle being completed. Hence these intersections form a curved summit line lowest against the windows or smaller sides of the oblong. This summit line of the vaulting of the building in the direction of its length forms a series of curves, though from the angle under which it is seen it is scarcely perceptible. Mr. Ware says, "It is observable, in the construction of this vault, that the principle of using freestone for the ribs, and toph for the panels, has not been followed; but the whole vault has been *got out* of the same description of stone, and with an uniform face, and the panels worked afterwards, and reduced to a tenuity hardly credible except from measurement. The artists of this building might be trusted in the decoration of a vault with what is now called tracery; they knew how to render it the chief support, and what was the superfluous stone to be taken away: every part has a place, not only proper, but necessary; and in the ribs which adorn the vault we may in vain look for false positions. This is the ocular music which affords universal pleasure."

Fig. 35.

We now return to the consideration of two more modes of simple vaulting. In England, summit ribs of the vault are almost always found running longitudinally and transversely in the various examples. In Germany the summit ribs are more frequently omitted than introduced. Thus in the example *fig. 32.*, the scheme is merely a square diagonally placed within the severy, subdivided into four parts and connected with the base-points of the groins by ribs not parallel to the alternate sides of the inserted square. This, however, sometimes occurs in English buildings, as in the monument of Archbishop Stratford, at Canterbury Cathedral; though in that the central portion is not domical. It is to be remarked that the intersecting arches are not of equal height, otherwise the arrangement could not occur.

In the example *fig. 36.*, the arrangement completely assumes what Mr. Willis calls the stellar form. Here in the sofit a star of six points is the figure on which the projection depends, the points radiating from the angles of an hexagon, and thus forming a cluster of lozenges whose middle longitudinal sides produce another longitudinal lozenge to connect the centres of the pattern. The longitudinal arches are, as in the preceding figure, lower than the transverse arches. Mr. Willis says, "the principal distinction between these and our own fan-vaulting is the substitution of lozenge-headed compartments in the fans, for the English horizontal transom rib. We have also lozenge-headed compartments in our early vaulting, but they are never so symmetrically arranged in stars throughout."

Fig. 36.

From the simple lines or principles above given it is easy to perceive through what numberless ramifications of form they may be carried.

## SECT. V.

## SHAFTS.

It is not our intention to discuss, at any length, the forms of the piers or shafts whereon the vaults just mentioned were received. Their various configurations would exhaust much more space than we can bestow on them, or than is necessary to give for the advantage of the reader. From extremely simple cylindrical shafts at the beginning, they gradually advanced to shafts of a complicated, or apparently complicated, description.

The shafts of the vaults of the earliest period for carrying the walls of the nave were square, as at the cathedral at Worms. The first step to their relief seems to have been the application of engaged columns to them, as in *fig. 37*. The cylindrical shaft is usual in

Fig. 37.

Fig. 38.

England and elsewhere. In the twelfth century the shaft begins to take the form on its plan of a Greek cross (*fig. 38*.), with engaged columns in its angles as well as on its principal faces. After this came the shaft clustered with columns in various ways, not indeed correspondent always with the vaulting ribs, but so arranged that the groups of the latter are generally received on *colonnets* or small columns, which are also provided for the moulded soffits of the arches of the nave and choir. In the latter part of the fifteenth century the *colonnets* gradually disappeared, and the shafts became surrounded by mouldings, or rather wrought on the plan into series of mouldings.

In the second period just named, engaged *colonnets* for receiving the vault ribs rise from corbels, and sometimes the ribs themselves spring from them, as in Lincoln, Salisbury, and other cathedrals. For the details of these and other matters of the like nature, the reader may refer to the works published by Mr. Britton and others, in which every minor arrangement will be found for the use of the practical man, the student, and the amateur. For the use of the latter in making surveys of buildings, we think it useful to subjoin the following recommendation from the "Remarks" of Mr. Willis:—"In making architectural notes, the plan of a pier should always be accompanied with indications of the distribution of its parts to the vaulting ribs and arches which it carries. The mere plan of the pier by itself conveys but small information; for it often happens that the identical pier may be distributed in many different ways, and that these differences constitute the only characters that distinguish the practice of one age or country from another. *Fig. 39*. shows one way in which the plan alone may be made to convey these particulars. The dotted lines, drawn from the respective members of the pier, mark the direction of the ribs and arches; and upon each of these at a small distance from the pier are placed vertical sections of these ribs, as at ABCD."

The bases of the shafts in the eleventh and twelfth centuries are often chamfered and frequently moulded in the Attic form, more or less modified and debased. In the latter period the Attic base is sometimes found almost pure. In all the ages the torus plays a considerable part in their composition, and their variety is infinite. In the fifteenth century

Fig. 39.

the type is pretty uniform. The ogee is prevalent, the concave part whereof, much flattened above, is very long compared with the convex part of it: this is generally surmounted with a torus, and then a bead, or sometimes with another small ogee. The group is then borne by a prismatic plinth; but for all these, as in the case of shafts just mentioned, reference must be made to the works of Britton, Pugin, and others.

## WINDOWS.

In the body of the work we have, under each period of Gothic Architecture, given a description in general terms of the windows prevailing at the several times. It has been thought it might be advantageous to bring a few examples before the eye. They are, however, inserted merely for the purpose of showing the gradual change in their forms and combinations, which are almost infinite in number, and yet the latter are far from exhausted.

The most ancient windows are extremely small, always semicircular headed, and without moulded archivolts. They are usually with a single light, except in belfry towers where we often find them divided into two by a shaft with a capital, as in the tower at St Albans, which is here given (*fig. 40.*). The simple plain head, however, in the latter part of the first

Fig. 40. ST. ALBAN'S.

Fig. 41. REAUMESERT.

Fig. 42. TRINITY CHAPEL.

period was more or less ornamented with the chevron or zigzag, and other ornaments of the time, as in *fig. 41.* One of the greatest and most striking changes brought in by the pointed style was that of introducing, from the suddenly elongated dimensions of its windows, a blaze of light into its edifices, which, from the low and narrow dimensions of their predecessors, were masses of gloom. From the beginning of the twelfth century we see them lengthened in a surprising manner, and terminating with a lancet-head and sometimes with a trefoil. An instance of the simple lancet-head is given in *fig. 42.*, from the Trinity Chapel at Canterbury. Sometimes an elegant combination is obtained by grouping three of these lancet-headed windows together, the centre rising considerably in height above the side ones, as at Salisbury Cathedral. (See *fig. 43.*) In an example at Lincoln (*fig. 44.*), the height of the group is equal;

Fig. 43. SALISBURY.

Fig. 44. LINCOLN.

but the light of the centre being wider than the two side lights, the curvature of the arches of the latter is necessarily much less than that to the former, and the effect is neither graceful nor satisfactory. There were, however, many other arrangements in designing these lancet-headed windows than the single and triple ones just mentioned. Two four,

and five lights occasionally form the group. Of the last-named, are windows at Irthlingborough, in Warwickshire, and at Oundle, in Northamptonshire, in which the lights on the sides gradually rise up to the centre one. In the latter part of the period, heads finish with trefoils; the mullions are moulded and finished, both inside and outside, with shafts or colonette, from the capitals whereof spring the mouldings of the subdivisions.

Fig. 45.  
PAINTED CHAMBER.

By perforating the space between the heads of two adjoining lancet-headed windows, as in the painted chamber (*fig. 45.*), the elements of the ornamented window are obtained. To cover it, however, ornamentally, the enclosing arch must be depressed and modified; and at Ely (*fig. 46.*), we find an example for illustrating the remark. The lozenge-shaped form between the heads of the arches is converted into a circle, which, as well as the heads of the lights, is foliated.

Fig. 46. ELY.

Instead of a single circle inserted in the head of the window, we then have them with three foliated circles, as at Lincoln, one above and two below; in the east window of its upper part having one large circle, besides its containing similar ones in the heads of the side lights. The windows just described belong to a transition style between the early English Gothic and the ornamented; but the ornamented windows of the fourteenth century exhibit in their general form and details a vast variance from them in the easy unbroken flow of the tracery with which they abound.

Of the next stage come the examples shown by *fig. 47.*, Merton College Chapel, and *fig.*

Fig. 47. MERTON COLLEGE.

Fig. 48. OXFORD.

Fig. 49. ST. OUE.

48., Cathedral, Oxford; the latter whereof has a tendency toward the Flamboyant style, which has been before mentioned, and which, in the fourteenth century, had thoroughly established itself in France, as we may observe in the windows of the church of St. Ouen, at Rouen, exhibited in *fig. 49.* It may be observed that the principal lights are seldom divided by transoms; when they, however, occur they are mostly plain, and rarely embattled. Though the ogee head is often found, the usual form is that of the simple-pointed arch. In the clerestory, square-headed windows are often seen, but more often in other parts of the edifice. In the preceding as well as in this period, the window bounded by three equilaterally segmental curves foliated more or less as the date increases. The arrangement of the tracery of windows has, by the French antiquaries, been divided into two classes — *Rayonnant* and *Flamboyant*. Their *Rayonnant*, so called on account of the great part the circle plays in it, and on whose radii its leading forms are dependent, was flourishing throughout the fourteenth century in France. The *Flamboyant* or tertiary pointed style followed it. We have, we think, had occasion before, in this work, to observe that the Continent preceded us in each style as much as half a century.

After this comes the Florid style in which the edifices seem to consist almost entirely of windows, and those of the most highly ornamented description. It is scarcely necessary to do more than exhibit the figures for a comprehension of the nature of the change which took place; in short, the introduction of the Tudor arch alone was sufficient hint for a totally new system. In the example (*fig. 50.*), of a window at Cawston Church, we may observe the commencement of the use of transoms, which at length were repeated twice and even more by the

Fig. 50.

height of the window, and indeed became necessary for affording stays to the lengthy mullions that came into use. *Fig. 51.* is an example of the square-headed window of the

Fig. 51. NORWICH.

Fig. 52. AYLHAM.

period, and *fig. 52.* of a Tudor-headed window at Aylsham. Another example may be referred to in *fig. 200.* of this work.

#### CIRCULAR WINDOWS.

The large circular windows so frequently seen in the transepts of churches, and sometimes at the west ends of them, and going by the general name of rose windows, seem to have originated from the *oculi* with which the tympana of the ancient basilicæ were pierced, and which are still observable in monuments of the eleventh century. For the study of this species of window the edifices of France furnish the most abundant means, many of them being of exquisite composition, and in our opinion far surpassing any elsewhere to be seen.

It is scarcely previous to the twelfth century that they can be fairly called rose windows; before that period they are more properly denominated wheel windows, the radiating mullions resembling the spokes of a wheel and being formed of small columns regularly furnished with bases and capitals, and connected at top by semicircular arches or by trefoils. By many the more decorated circular window has been called the *marigold* window, but we scarcely know why that should have been done. The rose windows are used in gables, but their dimensions are then generally smaller and they are often enclosed in segmental curves whose versed sines form an equilateral triangle or a segmental square.

An early specimen of the wheel window is in Barfreston Church, (see *fig. 180.*), wherein it is manifestly later than the other parts of the front. The example from Patrixborne (*fig. 53.*) is a curious and early example of the wheel window; herein, and indeed in all the minor examples, a single order of columns is disposed round the centre; but in the south transept at York Cathedral (*fig. 54.*) we have a noble instance of this species,—a double order of columns being employed connected by foliation above the capitals of the

Fig. 53. PATRIBORNE.

Fig. 54. YORK.

Fig. 55. ST. DAVID'S.

columns. This is of the thirteenth century. As the early style came in, the columns would of course give place to the mullion, as in the elegant example from St. David's,

shown in *fig. 55*. The two following examples (*figs. 56. and 57.*) from Westminster, and Winchester Palace, Southwark, are both of the fourteenth century. The first is not the

Fig. 56. WESTMINSTER.

Fig. 57. WINCHESTER PALACE, SOUTHWARK.

original window, but we have reason to believe it was accurately remade from the original one. The latter is a most elegant arrangement flowing from the continued sides of the central hexagon, and consequently forming a series of equilateral triangles decorated with foliation. It was placed in the gable of the great hall of the palace, which hall was spanned by a timber roof of very beautiful and ingenious construction, a few years since destroyed by fire, after which the wall containing the window was taken down.

During the period of the three last examples in this country, the French were making rapid strides towards that era in which their Flamboyant was to be stifled and extinguished by the introduction of the Renaissance, on which we shall hereafter have to make some remarks, and perhaps produce some examples. In the church of St. Ouen, the circular window appended in *fig. 58.* (middle of the fourteenth century) exhibits the extraordinary difference between French and English examples of the same date. Beautiful as many of the English examples undoubtedly are, we know of none that is equal to this for the easy and elegant flow of the tracery whereof it is composed. The leading points it will be seen are dependent on the hexagon, but, those determined, it appears to branch off from the centre with unchecked luxuriance, preserving, nevertheless, a purity in its forms quite in character with the exquisite edifice it assists to light. The detail of this window may be advantageously studied in Pugin's *Antiquities of Normandy*.

Fig. 58. ST. OUEN.

Fig. 59. WYKEN CHURCH.

#### DOORWAYS.

It is almost needless to observe that through the several changes of style the doorways followed their several forms; our duty will, therefore, be to do little more than present the representations of four or five examples to the notice of the reader. The Prior's entrance at Ely (*fig. 187. p. 173.*) is a fine specimen of the Norman doorway highly decorated. The earlier Norman doorways were designed with but little carving. They are, as in *fig. 59.*, generally placed within a semicircular arch, borne by columns recessed from the wall, and the whole

They are, as in *fig. 59.*, generally placed within a semicircular arch, borne by columns recessed from the wall, and the whole

surmounted with a dripstone. In the cut above referred to (187.), it will be seen that the semicircular head of the door is filled in level with the springing, and sculptured with a figure of our Saviour in a sitting attitude; his right arm is raised, and in his left is a book. What is termed the vesica piscis, of which we have already treated in this Appendix, surrounds the composition, which is supported by an angel on each side. These representations are frequently met with in Norman doorways. Many examples are composed of a series of recesses, each spanned by semicircular arches springing from square jambs, and occupied by insulated columns; though sometimes the columns are wanting and the recesses run down to the plinth. The arches are very often decorated with the chevron, zigzag, and other Norman ornaments. There are but few Norman porches; of them Malmesbury Abbey Church is perhaps the finest example.

The early English doorways have the same character as the windows of the period; the smaller ones are often recessed with columns, from which a pointed arch is twined with a cut moulding on it, and a dripstone over it. The more important doors, however, are mostly in two divisions separated by a pier column, and with foliated heads. These are generally grouped under one arch, springing from clustered columns on each side, and the space over the openings is filled in, and decorated with a quatrefoil, as in the doorway to the chapter-house, Litchfield (*fig. 60.*). Sculpture often occurs in the arrangement.

Fig. 60. LITCHFIELD.

Fig. 61. ST. NICHOLAS, LYNN.

Porches appear in this period to have been extensively used, as at Salisbury, Wells, and even in small parish churches. The door *fig. 61.* is a curious example of the latter part of the period: it is from the chapel of St. Nicholas, at Lynn. This belongs to the decorated English period.

*Fig. 62.,* from Tattershall Castle, belongs to the Florid English style, whose simplest

Fig. 62. TATTERSHALL CASTLE.

Fig. 63. ST. GEORGE'S CHAPEL.

doorways were with the depressed or Tudor arch, and without the square head which appears in the example. The more ornamental ones were crocketed, and terminated with finials, as appears in *fig. 64.*, from King's College Chapel, Cambridge. *Fig. 63.*, from St. George's Chapel, at Windsor, though later in date, is more simple than the last, notwithstanding the exuberance of ornament and tracery had then nearly attained to its meridian. The porches of this period exceed in profuseness of decoration those of the preceding style: they were almost universally adopted. The south porch of Gloucester and the south-west porch of Canterbury are beautiful examples. In the former, canopied niches occupy the front over the doorway, the front being crowned with an embattled parapet of pierced panelling, and at the quoins are turrets embattled and finished with crocketed pinnacles.

Fig. 64.

KING'S COLLEGE, CHAPEL.

## SYMBOLS.

The constant occurrence of symbols in the edifices of the middle ages induces us to think it may be useful to insert a list of them, as attached to the Apostles and Saints, most commonly found.

## HOLY APOSTLES.

- St. Peter.*—Bears a key, or two keys with different wards.  
*St. Andrew.*—Leans on a cross, so called from him; called by heralds the "saltire."  
*St. John Evangelist.*—With a chalice, in which is a living serpent. When this symbol is used, the eagle, another symbol of him, is never given.  
*St. Bartholomew.*—With a flaying knife.  
*St. James the Less.*—A fuller's staff, bearing a small square banner.  
*St. James the Greater.*—A pilgrim's staff, hat, and escarp shell.  
*St. Thomas.*—An arrow or with a long staff.  
*St. Simon.*—A long saw.  
*St. Jude.*—A club.  
*St. Matthias.*—A hatchet.  
*St. Philip.*—Leans on a spear; or has a long cross in the shape of a T.  
*St. Matthew.*—A knife or dagger.  
*St. Mark.*—A winged lion.  
*St. Luke.*—A bull.  
*St. John.*—An eagle.  
*St. Paul.*—An elevated sword, or two swords in saltire.  
*St. John Baptist.*—An Agnus Dei.  
*St. Stephen.*—With stones in his lap.

## SAINTS.

- St. Agatha.*—Her breast torn by pincers.

- St. Agnes.*—A lamb at her feet.  
*St. Aidan.*—A stag crouching at his feet.  
*St. Alphege.*—His chasuble full of stones.  
*St. Anagradesma.*—Covered with leprosy.  
*St. Anne.*—Teaching the Blessed Virgin to read. Her finger usually pointing to the words *Radix Jesse floruit*.  
*St. Antony, Eremit.*—Devil appears to him in the shape of a goat.  
*St. Antony of Padua.*—Accompanied by a pig.  
*St. Apollonia.*—With a tooth.  
*St. Barbara.*—With a tower in her hands.  
*St. Blaise.*—With a woolcomb.  
*St. Boniface.*—Hewing down an oak.  
*St. Britius.*—With a child in his arms.  
*St. Canute.*—Lying at the foot of the altar.  
*St. Catherine.*—With a wheel and sword.  
*St. Cecilia.*—With an organ.  
*St. Christopher.*—A giant carrying the infant Saviour on his shoulder across a stream. A monk, or female figure, with a lantern on the further side.  
*St. Clement.*—With an anchor.  
*St. David.*—Preaching on a hill.  
*St. Denis.*—With his head in his hands.  
*St. Dorothy.*—Bears a nosegay in one hand and a sword in the other.  
*St. Dunstan.*—Bears a harp.  
*St. Edith.*—Washing a beggar's feet.  
*St. Edmund.*—Fastened to a tree and pierced with arrows.

*St. Edward.*—Bearing in his hand the Gospel of *St. John*.

*St. Eunuchus.*—A dove lighting on his head.

*St. Etheldreda, Abbess.*—Asleep, a young tree blossoming over her head.

*St. Eustachius, or St. Hubert.*—A stag appearing to him, with a cross between its horns.

*St. Fabian.*—Kneeling at the block with a triple crown at his side.

*St. Faith.*—With a bundle of rods.

*St. George.*—With the Dragon.

*St. Gertrude, Abbess.*—With a loaf.

*St. Giles, Abbot.*—A hind with an arrow piercing her neck, standing on her hind legs, and resting her feet in his lap.

*St. Gudula.*—With a lantern.

*St. Hilary.*—With three books.

*St. Hippolytus.*—Torn by wild horses.

*St. Hugh.*—With a lantern.

*St. Januarius.*—Lighting a fire.

*St. Joachim.*—With a staff, and two doves in a basket.

*St. Lawrence.*—With a gridiron.

*St. Magnus.*—Restoring sight to a blind man.

*St. Margaret.*—Trampling on a dragon, a crosier in her hands.

*St. Martin.*—Giving half his cloak to a beggar.

*St. Nicholas.*—With three naked children in a tub, in the end whereof rests his pastoral staff.

*St. Odilo, Abbot.*—With two goblets.

*St. Pancras.*—Trampling on a Saracen, a palm branch in his right hand.

*St. Richard.*—A chalice at his feet.

*St. Rosaly.*—With a rock in her arms.

*St. Sebastian.*—As *St. Edmund*, but without a crown.

*St. Ursula.*—Surrounded with virgins much less in size than herself.

*St. Vincent.*—On the rack.

*St. Walburga.*—Oil distilling from her hand.

*St. Waltheof.*—Kneeling at the block, the sun rising.

*St. Winifred, Abbess.*—With her head in her arms.

*St. Wulfstan.*—Striking his pastoral staff on a tomb.

THE BLESSED VIRGIN is usually represented—

1. At the Annunciation, with an almond-tree flourishing in a flower-pot.
2. At her Purification, with a pair of turtle doves.
3. In her Agony, with a sword piercing her heart.
4. In her "*Repose*" (death).
5. In her Assumption.
6. With the blessed Saviour in her lap.
7. In her Ecstasy, kneeling at a faldstool, which faces the Temple, the Holy Dove descending on her.

*Martyrs* hold palms; *Virgins*, lamps, or, if also *Martyrs*, lilies and roses; *Confessors*, lilies; *Patriarchs*, wheels.

*Glories* round heads are circular, except when living prelates eminent for holiness are represented, when they are square.

The cross, a symbol of Christianity has very naturally been extensively used in the monuments of the middle ages. It is unnecessary to give the ornamental and profusely decorated examples, which the student everywhere finds, and we shall therefore confine ourselves to the simple forms by which each cross is distinguished. When the two branches of the cross are equal in length, as in *fig. 65.*, the cross is called a Greek cross, and when the stem

Fig. 65.

Fig. 70.

Fig. 71.

Fig. 72.

Fig. 73.

is longer than the arms, as in *fig. 66.*, it is a Roman or Latin cross. When the figure has two arms, one longer than the other (the upper one meant as a representation of the inscription which was placed over the head of Christ), it is known by the name of the Lorraine cross, and has received that name from its being a bearing in the arms of the Dukes of Lorraine. It is represented in *fig. 67.* By our own heralds this is called a patriarchal cross. The next (*fig. 68.*), whose arms are triple, is the papal cross, and is one of the em-

blems of the papacy, signifying, perhaps, like the triple crown, or tiara, the triple sovereignty over the universal church, the suffering church, and the triumphant church.

The great majority of the western churches, with transepts, are constructed in the form of a Latin cross, those in the form of the Greek cross being very rare. Those in the form of the Lorraine cross are still rarer, and yet rarer are those constructed with triple transepts.

There is another form (*fig. 69.*), called the truncated or *tau* cross, having the form of that letter, on which, as a plan, a few churches have been built.

Considered as respects their contours, the cross in blason has been variously shaped and named. Thus, *fig. 70.*, in which the extremities widen as they recede from the centre, is called a cross *patée*. This is met with more frequently than any of the others. It is seen in the nimbus, on tombs, on shields, upon coins, &c. *Fig. 71.* is by the French called *ancrée*, the extremities forming hooks, but by our own heralds it is called the cross *moline*. Crosses *flory* are those in which the ends are formed into trefoils, as is seen on the papal cross above mentioned (*fig. 68.*). *Fig. 72.* is a cross *potent*, and *fig. 73.* is the cross *cléchée*, as respects the outer lines of its form; when it is *voided*, as shown by the inner lines, the ground or field is seen on which it lies.

#### SECULAR ARCHITECTURE OF FRANCE.

The civil and domestic architecture of this country has been considered already in this work, to as great a length as the materials allowed, and the space which could be allotted to it. The history of it on an extensive scale is a great desideratum, and would form a most interesting work. The time rapidly passes in which it will be possible to accomplish such an end: year after year, some destructive fire consumes a mansion, which would serve to illustrate such a history, while decay is eating away those that remain. Pictorially something has been done, but the whole on so limited an extent that it might almost be said nothing has been done in the matter.

The timber houses of England have received some attention, but generally speaking those that remain are much inferior to the examples on the Continent. Our old Cheshire, from the prints of it that exist, seems to have exhibited a picturesque assemblage of them. In Caen are to be seen several specimens, and their appearance there, where in the neighbourhood there is abundance of stone, has been by some accounted for, by Henry V. appropriating the quarries for his own use, allowing the stone they supplied to be employed only in churches, castles, and fortresses. The houses in question are, by the Abbé de la Rue, supposed to have been built after the English came into possession of the town, in 1417; and are principally of chesnut. In the town of Troyes in Champagne, and many other places as at Rouen, are to be seen numberless instances of the ingenuity and contrivance employed on their construction. For those of this country reference may be had to Pugin's work.

In the first quarter of the fifteenth century, the buildings of France, not less in secular than in ecclesiastical architecture, began to assume a highly florid character, and before the end of the century it passed through several gradations. In the best part of the period, the plans are contrived with much attention to the unity and design of the edifice. They were on a scale of great magnitude. The effects of light and shade which appeared upon them were the result of deeply studied arrangement, and a sensitive feeling of the beauty flowing from proportion. In the openings especially, it is observable how much more graceful they become from their lessening in width and increasing in height. The composition throughout assumes a more pyramidal shape. The spires are covered with filigree work and often pierced, and the ridges of the roofs are terminated with open lacework of fleurs-de-lis and other ornaments showing out against the sky. Nothing is abrupt, everything is well considered. Though the style of the early part of the century gathered, as it rolled on, fresh accession of ornament from year to year, it did not become thoroughly affected by the Italian style until the more intimate communication between France and Italy, which followed the rash enterprise of Charles VIII. to become master of Naples after having overrun Italy, and the exertions of Louis XII., his successor, to recover the duchy of Milan in right of his grandmother Valentina. Among the artists who were induced by the last-named sovereign to visit the country, was Frà Giocondo, who, after the death of Bramante, was, in conjunction with Raffaello and San Gallo, architect of St. Peter's. He is believed to have been employed on Pont Notre Dame at Paris, and there is great reason to suppose he was also employed in the celebrated Palais de Justice, at Rouen, which we shall presently notice at some length, as one of the examples of secular architecture most illustrative of the style of its period. To the same master has been attributed the Château de Gaillon, well known to the visitors of Paris, by the portion of one of its façades now standing in the entrance court of the Ecole des Beaux Arts. This edifice, constructed for Cardinal George d'Amboise, called the French *Medicis*, and one of the nine sons of Pierre d'Amboise, every one of whom rose to great distinction, seems, from the comparative purity of its detail, to have anticipated, in fact, the Renaissance of a later date. M. Emeric David,

in his biographical notice of Frà Giocondo, thinks that artist was not engaged on the château, because "les formes gothiques du Château de Gaillon, sont bien éloignées du style que les bons architectes Italiens avaient déjà mis en vogue vers le même temps;" and again, because "il n'est pas vraisemblable que Joconde, reparti pour l'Italie en 1506, ait pu construire ce château en 1505." To which it has been answered, that the forms of Gaillon are not more Gothic than those of the ancient palace of the Chambre des Comptes, destroyed by fire in 1737, but of which partial representations have been preserved, as the corbel towers, the open staircase resembling that at the Sainte Chapelle, the lofty roofs and dormers, &c., all of the same style as those of the Hôtel de Cluny and the Palais de Justice at Rouen. Then, in respect of the date 1505; it was discovered on one of the pilasters, not set in its place, in the middle of some arabesques winding round a mitre with the episcopal keys; and this date may quite as well apply to the finishing as the commencement of the building. George d'Amboise, who died at Lyons in 1510, it has been said, never inhabited the château at all, for the ancient one was destroyed in 1423; but there seems abundant evidence that he did reside there, and was much esteemed for his noble actions, among which has been recorded that of presenting to a young lady, by way of dower, the price of some lands contiguous to his estate which he had proposed to buy of her father, who had no other means of providing for her than by the sale of them. "J'aime mieux acquérir un ami qu'un domaine," were his words on the occasion.

But to return to the subject, from which we have a little digressed. The style after the first quarter of the fifteenth century has been by many—first we believe by a Quarterly Reviewer, in 1821—called Burgundian Architecture, because, says the reviewer, it originated in the dominions of Philip the Good, Duke of Burgundy. No example can, he says, be dated anterior to his reign, and buildings having its characteristics are found in all the states which were united under his authority. We, however, do not think the name apposite, and certainly prefer calling it the early Flamboyant. Philip the Good succeeded to the duchy in 1419, having been born at Dijon in 1396; he died at Bruges in 1496; but all the germs of the style are traceable in the Church of St. Ouen of a considerably earlier date, and the carrying them out and adding to their efflorescence in secular buildings do not justify the name, especially as they appear at as early period in other parts of France as in Burgundy. There is no doubt that Philip was a great patron of the arts; and in respect of the palace at Dijon, and its great presence chamber, it was in unison with the spirit of the people, and seemed to declare the "lusty character of the prince who held his court there;" but that does not justify the designation whereof we are speaking. It is not improbable, however, that through his influence the style soon prevailed in Flanders, where from the duke's possessions in right of his mother, Margaret of Flanders, he was in considerable authority. The Hôtels de Ville, both at Louvain and Brussels, were erected during the period of his power. His riches at his death were enormous. "Malgré un gout pour le faste, les plaisirs, et les luxes, on trouve dans ses coffres à sa mort 400,000 écus d'or et 7,200 marcs d'argent, sans parler de 2,000,000 d'autres effets. Ce trésor, dit un moderne, semble n'avoir été rassemblé que pour être l'instrument des extravagances et de la ruine de son fils." (*L'Art de vérifier les Dates.*)

We now propose to submit to the student, in order as nearly chronological as possible, the mention of a few out of the infinite number of works in France that exemplify the style from 1420 up to 1531, when it may be said to have been lost in the pure Renaissance, confining ourselves (except in one instance) to secular architecture; and we regret our space restricts us to so few illustrations. A more interesting work or a more valuable one could not be undertaken, than a complete history of the architecture of France and the Netherlands between the years 1400 and 1525. Its phases, till the Flamboyant ceased, are so melted into each other, that to use the common phrase of transition, an absurd one, is utterly inappropriate.

Among the earliest examples is that of the Hôtel des Ambassadeurs at Dijon, which resembled in some degree several subsequent edifices at Bourges, Meilan, &c. It has, moreover, some historical interest beyond that of the architecture which remains of it, for here it is believed the sister of Philip the Good, above mentioned, contracted marriage with the Duke of Bedford, then governor of France. At a later period (1477), it was still appropriated to the residence of English ambassadors at the court of Burgundy. The date of this hotel is pretty well ascertained to have been about 1420.

The next example would seem to show the impropriety of giving the name of Burgundian to the style of which we are speaking. It is that of La Fontaine de la Croix, at Rouen, given in Britton's *Antiquities of Normandy*, in admirable plates from drawings by the late Augustus Pugin, on reference to which it will be seen there is scarcely an arrangement unanticipated of the more advanced period of the style, always reserving the freedom from a mixture of Italian architecture, which as yet was not interwoven with it. Here, in the tracery over the canopy work, is seen the same system of Flamboyant lines which pervades all the tracery of the beginning of the sixteenth century. The example also exhibits the interpenetration of members which afterwards became so compli-

cated, and on which we have already made some remarks. The date of this fountain is between 1422 and 1461; and it was erected by the Cardinal George d'Amboise, already noticed.

The palace at Dijon, which has been already mentioned, was in date subsequent to the Hôtel des Ambassadeurs just alluded to, and though altogether changed in its façade, still possesses within it many matters for the student of the style of this period of the art. It is now used for the accommodation of the authorities of the place in the shape of public offices, and a portion of it as a museum of the antiquities of the city. The date of its erection is about 1467. Although this part of our Appendix is dedicated to the consideration of secular architecture, we cannot refrain from reminding the reader that in this place are to be seen two monuments of the period, which are perfect keys to the style that prevailed at the time, in the monuments of the Dukes of Burgundy, Philippe-le-Hardi and Jean-sans-Peur, which were in the church of the Chartreuse. That of the last-named was executed by Juan de Huerta, assisted by other artists, about 1475.

At Nancy, the capital of Lorraine, still remains a portion of the ancient palace of its powerful dukes. Of its portail we present a representation in *fig. 74*. What remains within serves as barracks for the garrison. The date of it is about 1476. The shell-sculptured gable, with the candelabra-shaped ornaments bounding it, exhibit in an interesting way the contention between the past and coming styles. In the *balcons* the Flamboyant takes its place, and the foliations of the principal feature under the reigning pointed arch are inverted though set upon a ground in which the trefoils are in their proper position. The finials are inordinately large, and the elliptical form of the arch over the gateway is a step beyond what we call the Tudor arch. In every respect the example is one of great interest, and those persons who do not approve of an admixture of styles must at least admit that it is highly picturesque.

Fig. 74.

NANCY.

At Amboise was a palace of Charles VIII., which dates of 1483, but it fell into the hands of a possessor who has so modernised it that he has not left us the opportunity of even an observation upon it, and a succeeding proprietor consummated the Vandalism of the first named.

At Bourdeaux, whose beautiful cathedral, with its elegant spire, must be the admiration of all who have seen it, is an example of the period in the Gate du Caillau, built (in memory of the battle of Fornova) in 1494.

St. Quentin furnishes us with an Hôtel de Ville, whose date, 1495—1509, is as well verified by the style of the ornaments as by the rebus of the facetious canon Charles de Bovelles, given by M. du Sommerard as follows:—

D'un mouton et de cinq chevaux  
Toutes les têtes prendrey . . . . M.CCCC  
Et à icelles, sans nuls travaux,  
La queue d'un veau joindrez . . . . V  
Et au bout ajouterez  
Tous les quatre pieds d'une chatte . . . . IIII  
Rassemblez, et vous apprendrez

L'an de ma façon et ma date . . . . MCCCCVIII — 1509.

The town of St. Quentin possesses also a very fine church which was collegiate, and of which the King of France was premier chanoine.

At Caen is a curious instance of a castle in miniature, built by Girard de Nollent, about the end of the fifteenth century. Dawson Turner thus describes it: "It has four fronts; the windows are square-headed, and surrounded by elegant mouldings, but the mullions have been destroyed. One medallion yet remains over the entrance; and it is probable that the walls were originally covered with ornaments of this kind. Such at least is the case with the towers and walls, which, surrounding the dwelling, have given it a castellated appearance. The circular tower nearest the gate is dotted on all sides with busts in basso relievo, enclosed in medallions, and in great variety of character. One is a frowning warrior, arrayed in the helmet of an emperor of the lower empire; another is a damsel attired in a ruff; a third is a turbaned Turk. The borders of the medallions are equally diversified; the cordelière, well known in French heraldry, the vine leaf, the oak leaf, all appear as ornaments. The battlements are surmounted by two statues, apparently Neptune, or a sea god, and Hercules. These heathen deities not being very familiar to the good people of Caen, they have converted them, in imagination, into two gens d'armes mounting guard on the castle; and hence it is frequently called the *Château de la Gendarmerie*." Of the style displayed in this castle, Mr. Turner justly observes, we have no parallel in England.

At Orleans the ancient Hôtel de Ville, now used as a museum, exhibits another specimen of the style. It was commenced under Charles VIII., and finished in 1498, under Louis XII. At Blois the beautiful château whose four façades are of different styles, the eastern being of the period of Louis XII. This magnificent structure, now used as a barrack, "servit," says Du Sommérard, "de résidence à plus de cent têtes couronnées, princes et princesses." Valentin of Milan died here. It was the birth-place of Louis XII., who, as well as his successors, Francis I., Henri II., Charles IX., and Henri III., held his court here; and in 1588 it was the scene of the assassination of the Guises. The southern façade is of the eleventh century; that on the north side is very imposing and equally elegant, the interior of it as well as the exterior, belonging to the reign of Francis I. The *corps de logis* on the west, opposite the court of entrance, but which has never been finished, is as late as the time of Mansard, who was employed upon it by Gaston d'Orleans and the Grande Mademoiselle. From what has been said, it may be easily conceived, that it will furnish to the student a most valuable example for examining the different periods of French secular architecture. It is observed by the gentleman we have just quoted, "On ne peut nulle part trouver un moyen aussi facile et aussi curieux de juger comparativement ces divers styles, et surtout la vanité des efforts du plus grand architecte du XVII<sup>e</sup> siècle, dans sa lutte avec les maçons libres ses devanciers." Anne of Brittany and Gaston d'Orleans died in this château.

At Amboise there existed another splendid palace of Charles VIII. and Louis XII., but it has been entirely ruined by the alterations it underwent under the hands of a member of the conservative senate, who changed the old decorated dormers or lucarnes into modern

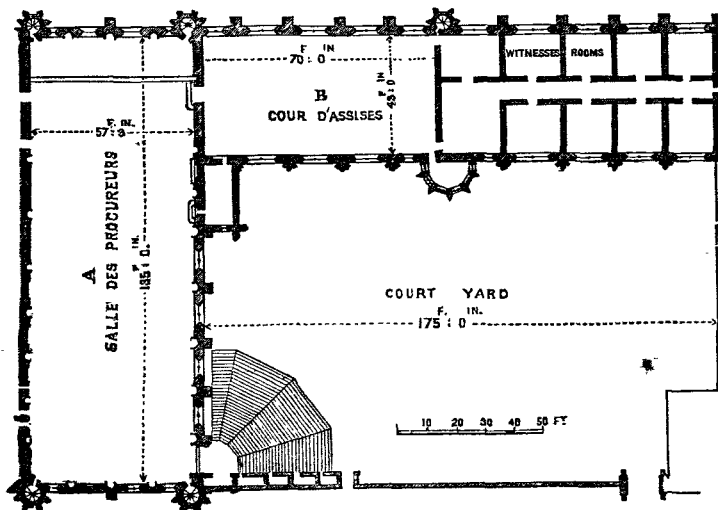

Fig. 76.

windows, placed gutters for carrying off the rain instead of the ancient gargouilles, and the like. The chapel to it, however, a most elegant morceau, still remains.

We now come to the time of one or two of the finest examples of the art of this period, the Palais de Justice and the Hotel Bourgtheroude, at Rouen. The first, begun in 1499 in the first year of the ministry of George d'Amboise, and finished in 1508. The plot on which this beautiful work stands, including the court-yard, is about three fifths of an English acre, and the arrangement of its plan is given, that is, of the ancient part of the building, in *fig. 75*. It is thus described by Dawson Turner:—"The three estates of the duchy of Normandy—the parliament, composed of the deputies of the church, the nobility, and the good towns—usually held their meeting in the Palace of Justice. Until the liberties of France were wholly extirpated by Richelieu, this body opposed a formidable resistance to the crown; and the Charte Normande was considered as great a safeguard to the liberties of the subject as Magna Charta used to be on this side of the channel. Here also the Court of Exchequer held its session." "This court, like our *Aula Regia*, long continued ambulatory, and attendant upon the person of the sovereign, and its sessions were held occasionally, and at his pleasure. The progress of society, however, required that the supreme tribunal should become stationary and permanent, that the suitors might know when and where they might prefer their claims. Philip the Fair, therefore, about the year 1300, began by exacting that the pleas should be held only at Rouen. Louis XII. remodelled the court, and gave it permanence, yielding in these measures to the prayer of the States of Normandy, and to the advice of his minister, the Cardinal d'Amboise." "When the Jews were expelled from Normandy, in 1181, the close or Jewry, in which they dwelled, escheated to the king." "In this *close* the palace was afterwards built." "The palace forms three sides of a quadrangle" (two of them only are ancient). "The fourth is occupied by an embattled wall and an elaborate gateway. The building was erected about the beginning of the sixteenth century; and with all its faults" (we are not aware what they are) "it is a fine adaptation of Gothic architecture to civil purposes." "The windows in the body of the building take flattened elliptic heads, and they are divided by one mullion and one transom. The mouldings are highly wrought, and enriched with foliage. The lucarne" (dormer) "windows are of a different design, and form the most characteristic feature of the front; they are pointed, and enriched with mullions and tracery, and are placed within triple canopies of nearly the same form, flanked by square pillars, terminating in tall crocketed pinnacles, some of them fronted with open arches, crowned with statues. The roof, as is usual in French and Flemish buildings of this date, is of a very high pitch, and harmonises well with the proportions of the building. An oriel, or rather tower, of enriched workmanship projects into the court, and varies the elevations" (an object the designer never once thought about, inasmuch as in all mediæval buildings, the first consideration was convenience, and then the skill to make convenience agreeable to the eye—an invaluable rule to the architect). "On the left-hand side of the court, a wide flight of steps leads to the *Salle des Procureurs*" (marked A on the plan), "a place originally designed as an exchange for the merchants of the city" (*sed quære*), "who had previously been in the habit of assembling for that purpose in the Cathedral. It is 160 feet in length by 50 feet in breadth." The description is generally good, or we should not have adopted it; but Mr. Turner has made a strange mistake in the length he has given, which is 25 feet more than the *salle* really is, an error which we are surprised the *Quarterly Review* did not find out, for reviewers are supposed to know everything. The true dimensions are 135 feet by 57 feet 3 inches. They are so given in Britton's *Normandy*, and we will vouch from our own measurement for their accuracy. The room B, now the *Cour d'Assises*, has remained in its original state; the ceiling is of oak, black through age, and is arranged in compartments with a profusion of carving and gilt ornaments. The bosses of the ceiling are gone, as are also the doors which were enriched with sculpture, and the original chimney-piece. Of this room, Heylin says "it is so gallantly perfect, and richly built, that I must needs confess it surpasseth all the rooms that ever I saw in my life. The palace of the Louvre hath nothing in it comparable; the ceiling is all inlaid with gold, yet doth the workmanship exceed the matter. Round the room are gnomonic sentences, admonishing the judges, jurors, witnesses, and suitors of their duties." The basement story of the *salle* is, or used to be, occupied as a prison.

*Fig. 76*, exhibits a portion of the south front of the building. The ellipse seems almost to have superseded the pointed arch in the leading forms, over which the crocketed labels or drips, in curves of contrary flexure, flow with surprising elegance. It is only in the lucarnes we find the pointed arch; and there it is almost subdued by the surrounding accessories. The connection of the lucarnes with the turrets of the façade by means of flying buttresses is most beautiful, and no less ingenious in the contrivance: their height, from the ground to the top of the finials, is 78 ft. 6 in. The octangular turrets at the end of the *salle*, next the Rue St. Lo, contain a very pretty example of penetration over the heads of the pointed arch. In the story above the basement, as also in the lucarnes, the sofites of the windows are rounded at the angles, or, as the French call it, have *cousinets arrondis*, as

Fig. 76.

ROUEN PALAIS DE JUSTICE.

usual in the style, those in the principal story being, besides, slightly segmental. In the tracery of the parapet it is singular to find the quatrefoils centered throughout with what is called the Tudor rose. The arches rising above the parapet, which are crocketed and of contrary flexure, have statues substituted for finials. The richness of the ornamentation of the whole is such that we know no other example, except that of the *Hôtel de Bourgtheroude* in the same city, that can vie with it.

Fig. 77. is a section of the *salle*. The roof presents little for remark. It is bold and simple, and seems scarcely in harmony with the rest of the place. It is impossible to form an adequate notion of this splendid monument from the figures here given, owing to the necessary smallness of the scale. Those who are desirous of thoroughly understanding its details will be gratified by referring to the plates of it in Britton's *Normandy*.

There is no city wherein the style of the period whereof we are treating can be better studied than Rouen. It possesses, both in secular as well as ecclesiastical architecture, all that the student can desire. The *Hôtel de Bourgtheroude*, in the *Place de la Fucelle*, is about the same age as the *Palais de Justice* we have just described, or perhaps three or four years later in the finishing. In some respects it is more elaborate in the ornaments and the abundance of sculpture. The entire front is divided into bays by slender buttresses or pilasters, the spaces between them being filled with bassi-relievi; every inch of space, indeed, in the building has been ornamented. This building, or rather a portion of it, is given in

Fig. 77.

ROUEN PALAIS DE JUSTICE.

Britton's *Normandy*. Some of the bassi-rilievi are engraved and described by Langlois, in his *Description Historique des Maisons de Rouen*.

The well-known Hôtel de Cluny at Paris, of which a portion is given in *fig. 78.*, belongs to the period, though commenced somewhat earlier. This hotel, as well as the Château de Gaillon, was a dependence of the archbishopric of Rouen. After some interruption of the

Fig. 78.

HÔTEL DE CLUNY.

works, they were resumed in 1490, by Jacques d'Amboise, Abbé of Cluny, and afterwards Bishop of Clermont. He was brother to the celebrated George d'Amboise, of whom we have had so much to speak.

To the north-west of Caen (about ten miles) is the Château Fontaine le Henri, a considerable portion whereof is of the period under view. A part of the west front is given in *fig. 79.* Dawson Turner says, "This château is a noble building, and a characteristic specimen of the residences of the French noblesse during the latter part of the fifteenth century; at which period there is no doubt of its having been erected, although no records whatever are left upon the subject. Fontaine le Henri was then still in the possession of the family of Harcourt, whose fortune and consequence might naturally be expected to give rise to a similar building." Most of the exterior surface of this building is covered with medallions, scrolls, friezes, canopies, statues, and arabesques, in bas relief, worked with extraordinary care, and of great beauty.

At Gaillon there now remain very few vestiges of the celebrated château of the Archbishops of Rouen. We have above mentioned that a portion of it is set up in the court of the Ecole des Beaux Arts at Paris.

Near St. Amand is the Château de Meilan, bearing a considerable resemblance in character to the Hôtel de Cluny, but much richer in the ornamentation. The walls abound with the arms of Chaumont, which was from the thirteenth century in the family of Amboise; and Jacques d'Amboise became, on the death of his father, lord of Chaumont and Meilan.

Fig. 79.

CHATEAU FONTAINE DE VIERGE.

Fig. 80.

ST. JACQUES DIERPPE.

At Clermont (Auvergne) was a beautiful fountain erected by Jacques d'Amboise, about 1512, opposite the cathedral. But it was much injured by its removal in 1799 to another spot; and for the octagonal *tazza* covered with arabesques was substituted a circular one, besides being denuded of much of its sculpture.

We have now enumerated a few of the châteaux of France, to which reference may be had for an insight into the domestic architecture of the country, previous to the complete triumph of the Renaissance. *Fig. 80.*, though belonging to the ecclesiastical branch of the subject, is a very curious example of the dying struggles of the style called the Flamboyant. It is from the church of St. Jacques at Dieppe.

## HÔTELS DE VILLE.

At a very early period the cities on the Continent that rose into importance were, for the better regulation of the inhabitants, governed by a municipal body composed of their principal inhabitants, whose business it was to make laws and ordinances for the good order of the place generally, and the proper governance of the different guilds or trades. For the convenience of these bodies were erected those magnificent edifices, some three or four whereof we are about to notice, as examples of public secular architecture in the middle of the fifteenth century. We have chosen the Belgian examples, as most splendid, to remark upon; but it is not to be understood that fine specimens are only to be found in that country. France and Germany abound with edifices whose destination is that we have just described, and a very voluminous work might be produced on the subject. Dallaway well observes, that "the Maisons de Ville, or town-houses, in many of the cities of Flanders engrossed, in a peculiar degree and extent, a style of grand and most richly ornamented architecture, superior even to that conspicuous in their churches of the highest order." These "are all of the fifteenth century." "The external surface of the whole building is literally encrusted with minute filigraïn in stone." Mr. D. says they are of the manner first introduced and patronised under Philip, duke of Burgundy,—a subject we have in this Appendix already discussed, and to which we consider it unnecessary to return, merely observing, by the way, that in the detail they are entirely wanting in the interpenetrating system of the mouldings which is so marked a characteristic of what has been called the Burgundian style.

Of the four principal hôtels de ville, that of Bruges is the earliest. Its date is 1377, and it was erected under the order of Louis de Maele, Count of Flanders; but as it presents nothing to dwell upon, and is before the period under our consideration, it is unnecessary to enter into further description of it.

The Hôtel de Ville of Brussels is the first of the class, an edifice, whether considered by itself, or as the dominant feature of a *place* surrounded by buildings of the most unique and varied appearance, the most interesting that we recollect anywhere to have contemplated. It appears to have been completed in 1445. *Fig. 81.* is a view of the façade, which is towards the east. There can be little doubt that a much more ancient building occupied this site, which has not been entirely removed; for in the northern side from the tower, the piers of the loggia, which on the basement extends along the front, consist, at least three of them, of columns whose date is evidently a century earlier, and which it is probable were left when the main front of the building was carried up. Indeed, it seems highly probable that at the time of the architect Van Ruysbroeck undertaking his part of the work, the hotel was in existence as high as the one-pair floor. The whole of the tower seems rather later than the date above given, which accords well enough with the northern wing. The authorities we have looked into scarcely, however, admit us to doubt its eor-rectness. One of the puzzles attending this example is, why the tower and spire do not stand in the centre of the front. We are of opinion, on this head, that the northern wing is of the length originally intended for each side of the centre, and that it was, in execution, lengthened out on the southern side for the acquisition of more room. Certainly the southern wing is rather later, and there is a carelessness about the detail which would seem to indicate that the burgomaster of the day found there was not enough space for the offices, and that, *comme qui couste*, he was determined to supply them. The proportions of the front would clearly have been more congenial to the style had the southern wing been restricted to the same number of bays as the northern. As the building stands executed, taking one of the bays on the northern side as a measuring unit, we have three measuring the central space for the tower, ten for the north wing, and eleven for the south wing; the height, to the top of the parapet, nine; to the ridge of the roof, thirteen; to the top of the spire, thirty-three. The tracery on the spire is very elegant, and is pierced throughout. It is 406 feet high, and crowned with a copper gilt colossal statue of St. Michael, the patron of the city, 18 feet high, which is so well balanced upon the pivot on which it stands that it is susceptible of motion with a very gentle wind. The interior of the edifice has a quadrangular court, with two modern fountains, statues of river gods with reeds and vases, as usual in such cases. The *Grande Salle* is that in which Charles V., in the height of his power, abdicated, in 1556, in favour of his son Philip. Besides this, there are many

Fig. 81.

BRUSSELS HOTEL DE VILLE.

interesting apartments, some whereof possess ceilings of great beauty. This beautiful monument is perhaps the most admirable example of the adaptation of the style to secular architecture that can be quoted.

Smaller in extent than the hôtel de ville we have just described, but more beautiful and symmetrical, is that of Louvain. It is the most perfect, in every respect, of this class of buildings in Europe. Nothing can surpass the richness and delicacy of the tracery upon it. Like that at Brussels, it consists of three stories, but has not, like it, any lofty tower. Commenced in 1448, it was not completed till 1493. It stands on a site of about 85 feet by 42 feet; so that it derives little advantage from its absolute magnitude, and perhaps appears less than it really is, from the great height of the roof, which is pierced by four tiers of dormers or lucarnes. The angles are flanked by turrets, of which some notion may be formed by reference to *fig. 82.*, and the ridge of the roof is received at each end by another turret corbelled over from the gables. The façade towards the *Place* extends rather more than the height, and is pierced with twenty-eight windows and two doorways, being ten openings in each story, the spaces between the windows being decorated with canopies, and groups of small figures from the Old Testament, some whereof are rather licentious. This

Fig. 52.

HOTEL DE VILLE, FOIVAIN.

charming edifice which, in its delicate rich tracery, had suffered much from time and the elements, when we last saw it, four or five years since, had at the joint expense of the town and government undergone a complete renovation. This had, stone by stone, been effected with great care and artistic skill, by a M. Goyers, and religiously accurate it appears to be. The new work has been saturated with oil: it is executed in very soft stone, which hardens with exposure to the air.

In form, though not in features, totally different from the hôtels de ville we have just left, is that at Ghent, never completed, but exhibiting, in what was executed of the design, a choice example of the last days of the Flamboyant. It was begun in 1481, and we perceive in it all those indications of change in the softness and curves, as well as in the lines of the foliage and tracery, that were never more to be repeated; for, were the style repeated and revived, it would be but mockery and a lie, as unsuitable and out of character with the habits of the age, from which alone a real style of architecture can ever spring. The subdivision of the building as to height is into two stories as to effect, though in reality there

are more; and the transoms, which abound in the apertures, seem to reign in accordance with the horizontal arrangement of lines which was so soon to supersede the flaming curves that had prevailed for nearly half a century.

## II.—DILAPIDATIONS.

The architect, in the course of his practice, is frequently called upon, and he must undertake the task, however uncongenial to his feelings, to ascertain the extent of neglect of a tenant in keeping his premises in proper order according to the covenants of the lease or agreement under which he holds the property. The owner of a tenement let to any person has a right to expect that it shall be delivered up to him, at the expiration of the term, in as good condition as the wear and tear of the time will permit; and the tenant is bound to make good what by his neglect or accident may have injured the premises. If the tenant fails in this, not only upon what was originally demised, but upon what may have been erected after he begins his occupation, he is bound to pay to the landlord a sum equal to what will restore the premises.

The general rule for determining what injuries are considered dilapidations, is to ascertain what is *fair wear* without accident, for such is not dilapidation. Injury by accident is that which happens suddenly, and perceptibly differing from wear, which occurs only by lengthened use. Thus the nosing of a step worn away is not dilapidation; but if such be broken away, instead of worn, it is a dilapidation. It may be said that accident is defined here with too much latitude, inasmuch as it takes account of that which occurs without apparent reason at any particular time; but we use the term in common language, and may cite as an example, that if the timbers of a floor decay, the floor will yield, even without a load upon it. When accident occurs, such alone does not limit the extent of the dilapidation, but also such injuries to the building as follow in its train. Thus, if the weatherboarding of a building decay from age, so long as the covering be complete and entire, it is no dilapidation; but if broken in any part, that is a dilapidation; and if from want of reparation any of the internal parts of the building be injured, such injury is a dilapidation: so if timber or timbers belonging to any part of a house merely decay, if it or they be still sufficient for the support of the house, no dilapidation can be chargeable; but if such timber or timbers give way, they must be replaced, and all parts made good which suffered by their failure. According to Woodfall (*Landlord and Tenant*), "waste may be done in houses by pulling them down or suffering them to be uncovered, whereby the rafters and other timbers of the house become rotten; but the bare suffering them to be uncovered, without rotting the timber, is not waste: so if a house be uncovered when the tenant cometh in, it is no waste in the tenant to suffer the same to fall down." In external covering, however, it seems that decay arising from inattention to it is dilapidation, even though no accident be the cause. It is always considered that though painting neglected is not itself a dilapidation, yet where decay arises from it, it is one.

Broken glass is not considered a dilapidation, unless there be more than one crack in the pane. Some, however, contend that while the glass is sufficiently entire to exclude the wind and weather, no waste is assignable. Generally it seems then to be the rule, that where accident occurs, it is a dilapidation.

Whatever the tenant has power to remove during the term cannot be chargeable with dilapidations. Upon this point the old rule is, that whatever is *fixed* to the freehold cannot be removed by the tenant: thus a lessee may erect barns or sheds or any building upon wooden or stone or other blocks laid on the surface of the ground, and take them down if he please without substituting anything in their place; but if the barns are fixed into the ground, they immediately become the property of the lessor. There seems, however, to be an exception in respect of buildings erected for the purposes of trade: hence not only coppers and ovens may be taken away, but workshops and the like erected by the tenant for his particular trade. This exception seems at first to have applied only to wooden buildings; but Lord Kenyon held that a brick chimney would prevent a tenant from removing a building, and decided that its being on a brick foundation would not do it. Though this opinion was not held by Lord Ellenborough, yet it was not because the buildings were of brick, but because they were erected for the purposes of agriculture, and not of trade. These matters, however, are not in the province of the architect. It is to be remembered, in all cases, that a lessee is bound to leave the premises in as good condition, after the removal of fixtures or improvements, as though they had never existed: thus, if a marble be substituted for a wooden chimney-piece, when the former is removed, the latter, or one of equal value, must be replaced. If a partition be put up and taken away, all damages to the adjacent work must be repaired.

## III.—COMPOUND INTEREST AND ANNUITY TABLES.

In a previous part of this work (797, *et seq.*) we have touched on the nature of compound interest and annuities; and as the architect is often called on to value property, we have thought it right to add some practical observations on the subject, and a set of Tables for the ready calculation of such matters, which we shall here explain.

TABLE FIRST contains the amount of 1*l.* put out to accumulate at compound interest for any number of years up to 100, at the several rates of 3, 4, 5, 6, 7, and 8 per cent. The amount of any other sum is found by multiplying the amount of 1*l.* found in the table at the given rate per cent., and for the given time, by the proposed sum.

## Example.

Required the amount of 755*l.* in 51 years, at 5 per cent.

Amount of 1 <i>l.</i> for 51 years at 5 per cent. is	-	-	-	-	-	12.040769
Given sum	-	-	-	-	-	755
						<hr/>
						£9080.780595

or 9090*l.* 15*s.* 7 $\frac{3}{10}$ *d.*

TABLE SECOND contains the present value of 1*l.* payable at the end of any number of years up to 100. The present value of any given sum payable at the expiration of any number of years is found by multiplying the present value of 1*l.* for the given number of years, at the proposed rate per cent., by the given sum or principal.

## Example.

Required the present value of 9090*l.* payable 51 years hence, compound interest being allowed at 5 per cent.

By the table, the present value of 1 <i>l.</i> payable at the expiration of						
51 years at 5 per cent. is	-	-	-	-	-	.083051
Given principal	-	-	-	-	-	9090
						<hr/>
						£754.933590

or 754*l.* 18*s.* 7 $\frac{1}{10}$ *d.*

TABLE THIRD contains the amount of an annuity of 1*l.* for any number of years, and is thus used. Take out the amount of 1*l.* answering to the given time and rate of interest: this multiplied by the given annuity will be the required amount.

## Example.

Required the amount of an annuity of 27*l.* in 21 years, at 5 per cent. compound interest.

Annuity of 1 <i>l.</i> in 21 years at 5 per cent.	-	-	-	-	-	35.719251
Annuity given	-	-	-	-	-	27
						<hr/>
						£964.419777

or 964*l.* 8*s.* 4 $\frac{7}{10}$ *d.*

TABLE FOURTH shows the present value of an annuity of 1*l.* for any number of years, at 3, 4, 5, 6, 7, and 8 per cent., and is used as follows:—

*First*, when the annuity commences immediately. Multiply the tabular number answering to the given years and rate of interest by the given annuity, and the product will be the value required.

## Example.

Required the present value of an annuity of 45*l.*, which is to continue 48 years, at the rate of 5 per cent.

Under 5 and opposite to 48 years is (years' purchase)	-	-	18.077157
Annuity given	-	-	45
			<hr/>
			£813.472065

or 813*l.* 9*s.* 5 $\frac{3}{10}$ *d.*

*Second*, when the annuity does not commence till after a certain number of years. Multiply the difference between the tabular numbers answering to the time of commencement and end, at the proposed rate of interest, by the given annuity, the product will be the present value required.

## Example.

An annuity of 40*l.* is to commence 20 years hence, and is to continue 30 years; required its present value, the rate of interest being 4 per cent.

Under 4 per cent. and opposite to 20 is	-	-	-	-	-	13 590326
Under 4 per cent. and opposite to 50 (20 + 30) is	-	-	-	-	-	21 482184
Difference	-	-	-	-	-	7 891858
Annuity given	-	-	-	-	-	40
						<u>£315 674320</u>

or 31*l.* 13*s.* 5 $\frac{1}{10}$ *d.*

TABLE FIFTH contains the annuity which 1*l.* will purchase, compound interest being allowed. The manner of using this table is obvious, from what has been said relative to the preceding tables.

## Example.

What annuity for 10 years will 500*l.* purchase, the rate of interest being 5 per cent.?

Under 5 and opposite to 10 is	-	-	-	-	-	129504
Principal given	-	-	-	-	-	500
						<u>£64 752000</u>

or 64*l.* 15*s.* 0 $\frac{2}{10}$ *d.*

TABLES SIXTH, SEVENTH, and EIGHTH are for finding the value of annuities on single and joint lives, and were constructed by Simpson, on the London bills of mortality.

To find the value of an annuity for a single life, at a proposed rate of interest, within the limits of the table, take from Table VI. the number answering to the given age and proposed rate of interest, which multiplied by the given annuity, the product will be the value required.

## Example.

What is the value of an annuity of 50*l.* upon a single life aged 40 years, according to the London bills of mortality, the rate of interest being 4 per cent.?

The value of an annuity of 1 <i>l.</i> for 40 years at 4 per cent. is	-	-	-	-	-	11 5
Annuity	-	-	-	-	-	50
						<u>£575</u>

To find the value of an annuity of two joint lives, multiply the number in Table VII. answering to the given ages, and at the proposed rate of interest, by the given annuity, and the product will be the required value.

## Example.

What is the value of an annuity of 60*l.* for two joint lives, the one being 30 and the other 40 years, interest at 4 per cent.?

The number answering to 30 and 40 years at 4 per cent. is	-	-	-	-	-	8 8
Annuity	-	-	-	-	-	60
						<u>£528 0</u>

To find the value of an annuity for the longest of two given lives, proceed as directed in the case immediately preceding, but using Table VIII., and the product will be the value.

## Example.

What is the value of an annuity of 60*l.* for the longest of two lives, the one being 30 and the other 40 years, interest at 4 per cent.

The tabular number answering at 4 per cent. is	-	-	-	-	-	15 9
Annuity	-	-	-	-	-	60
						<u>£954 0</u>

The first five tables which follow are printed from those of Smart; the remainder are from Simpson.

The calculations involving the valuation of annuities on lives are not very frequently imposed on the architect, but it is absolutely necessary he should be capable of performing them, as in the case of valuations of leases upon lives, which sometimes occur to him.

## THE FIRST TABLE OF COMPOUND INTEREST.

## IV. — VALUATION OF PROPERTY.

The valuations in which the architect is consulted are properly only those wherein buildings have been or may be erected; from which if he wander, the probability is that he will create difficulty for himself, tending to exhibit him as a pretender to knowledge not within the regular course of his occupation. The general principles, therefore, on which we propose to touch, are confined to the species of property above named, as distinguished from that in which the resident valuator near the spot in the different provinces is the best adviser, from the local knowledge he possesses. The auctioneers who with unblushing effrontery pretend to a knowledge of the value of property in the metropolis, are utterly incompetent to the duties they undertake, from an ignorance of the durability and cost of buildings, which can be attained by the practice and experience of the architect only.

Buildings may be so disadvantageously placed on their sites as to realise nothing like a proper interest on the money expended in their erection; and, indeed, so as altogether to destroy even the great value of the ground on which they are built. Thus, to place before the reader extreme cases, which generally best illustrate a subject, let him suppose a row of hovels built in Piccadilly, and a house like Apsley House placed in Wapping High Street. In both cases the productive value of the ground is destroyed, there being no inhabitants for such dwellings in the respective quarters of the town.

From this it must be evident that the value of town or city property, which consists principally of buildings, is divisible into two parts; namely, —

That arising from the value of the soil or site; and

That which arises from the value of the buildings placed upon it.

We will suppose for a house which is fairly let at a rent of 100*l.* per annum, no matter what the situation of it be, that it could be built for 1000*l.*, and that the proprietor or builder would be content with 7 per cent. for the outlay of his money, a rate by no means larger than he would be entitled to claim, seeing that the letting, after it is built, is a matter of speculation, and that loss of tenants and other casualties may temporarily deprive him of the interest of his capital. In this case, then, the rent of the mere building would be 70*l.*; and as the full rent assumed is 100*l.*,

$100 - 70 = 30$ , which is manifestly the value of the ground or ground rent.

Thus in the cases of valuation of freeholds, wherein the gross rent can be accurately ascertained, there can be no difficulty in coming at the real value of the ground rent, because the building rent, or that arising from the expenditure of money on the soil, can be immediately ascertained by the architect, with the rate of interest on it which it is fit the builder should have. The remainder of the rent is that inseparably attached to the value of the soil, and belongs to the ground landlord.

The reason for thus separating the two rents is this: the ground rent, attached as it is to the soil, is imperishable. It is true that the value of ground is constantly fluctuating from the power of fashion over certain localities; but with this the valuator cannot deal. The changes are slow; and the Lord Shaftesbury in the time of Charles II. would have little thought it possible, when he placed his residence in Aldersgate Street, that his successors would have dwelt in a house in Grosvenor Square; neither, even five and twenty years ago, did it cross the mind of the then possessor of the Grosvenor property that the Five Fields at Chelsea contained a mine of wealth in the ground rents of Belgrave and Eaton Squares. Such are the mutations of property, with which the present question is not involved, unless the gift of foresight, in a degree not to be expected, be given to the valuator. The other portion of the value of house property is strictly the result of the perishable part of it, namely, the building itself; and this is limited by the durability of the building, which has great relation to the time it has already existed, and to the substantiality with which it has been constructed. The durability, then, or the number of years a building will continue to realise the rent, is the second ingredient in a valuation, and is a point upon which none but an experienced person can properly decide.

The rate of interest which the buyer is content to obtain in the investment of his money in buildings, or, in other words, in the purchase of the perishable annuity arising from the building, will necessarily vary with the value of money in the market. In the compensation cases under public improvements, wherein it is obligatory on the owner to part with his property, the 5 per cent. rate of the table is generally used, by which the buyer makes too little interest on the perishable part of the property. Few would be inclined to invest money in such property at so low a rate, for a rent which every year, from wear and tear, becomes less valuable. Individuals understanding the subject would scarcely be found to purchase, unless they could make at least 7 per cent. for this part of the capital. In the cases above mentioned, twenty-five years' purchase, that is, 4 per cent., is the usual price at which the ground rent is taken.

We will, having thus prepared the student, present an example of a valuation conducted on the principles named. Thus, suppose a building and the ground on which it stands to be together worth 150*l.* per annum, and that its durability is such that a purchaser may count on receiving that rent during a term of fifty years. We will suppose the house to stand upon a plot of ground 24 feet in frontage, and 60 feet in depth; that the size of the house is 24 feet by 40 feet, and that to build a similar one would cost 1440*l.*, which, at a rate of 7 per cent. upon the expenditure, would produce a building rent of 100*l.* 16*s.* per annum.

	£	s.	d.	£	s.	d.
Now the total rent being	-	-	-	150	0	0
The rent arising from the building itself	-	-	-	100	16	0
The value of the mere ground must be	-	-	-	49	4	0

We therefore here have the imperishable part, viz. the ground, of the value of 49 <i>l.</i> 4 <i>s.</i> per annum, which, giving the purchaser 4 per cent. interest for his money, is twenty-five years' purchase for the fee-simple by the Fourth Table, that is	1230	0	0
An annuity (from the building) of 100 <i>l.</i> 16 <i>s.</i> , to continue for fifty years, is, by the Fourth Table at 5 per cent., worth 18·256 years' purchase, that is	1840	0	11
The value of the old materials at the end of the term, if taken to be pulled down and sold for 150 <i>l.</i> , will be that sum at the end of fifty years to be received at the present time, discounting at 5 per cent. from the Second Table $1107 \times 150$	=	16	12 1
Total value of the freehold	3086	13	0

In the above valuation the ground estimated by its frontage would be  $\frac{49*l.* 4*s.*}{24 \text{ feet}} = 41*s.* per foot, and ground is usually let by the foot when demised for building.$

The next case of valuation is that of a beneficial lease, in which the rent paid by the lessee is less than the actual value of the premises. The difference between them, therefore, is an annuity for the term of the lease, which is so much benefit to the lessee, and is estimated by the Fourth Table; thus,—

Suppose the actual value of given premises be	-	-	-	£100
Rent reserved by the lessor	-	-	-	50
Beneficial annuity belonging to the lessee	-	-	-	£50

If the term of the lease be twenty-one years, such is the length of the annuity, and the question stands as under:—

An annuity for twenty-one years, discounting at 5 per cent., is by the Fourth Table worth 12·8211 years' purchase, which multiplied by 50*l.* = £641 1*s.*

It is to be observed that the annuities must be clear after the deduction of all outgoing which may be necessary to keep it unencumbered.

Let us take another case.

A. takes a lease of ground at 10*l.* per annum, and lays out 1000*l.* on a sixty-one years' lease, interest being 3 per cent. How much must he receive as rent to replace the principal at the end of the term?

1000*l.* at 3 per cent. = 30*l.* + 10*l.* ground rent = 40*l.* improved rent.

14 per annum for sixty-one years at 3 per cent. will amount to 169*l.* (See Third Table.)

1000  
169 = 5*l.* 9*s.* = the sum to be laid out yearly.

And 30*l.* + 5*l.* 9*s.* = 35*l.* 9*s.*, or 3·59, is the rate of interest to secure or replace the principal at the end of the term without consideration of repairs, loss of tenants, insurance, &c.

In the valuation of warehouses, the only safe method of coming at the value of a rental is by the quantity of goods or tonnage they will contain, after leaving proper gangways, and not overloading the floors. In corn warehouses, however, the grain being distributed over the surface of the floor, the squares of floor are taken to come at the contents. Goods warehoused are paid for to the warehouseman usually at a weekly or monthly rent; and it is commonly considered that the profit he should make ought to be one half of the rent he pays to the landlord, so that in fact two thirds of the actual rent realised goes to the proprietor, and the other third to the warehouseman or lessee. The following is a table of the space occupied by different goods:—

Of cork there are	-	-	-	-	149·333	cube feet in a ton.
Of fir	-	-	-	-	65·163	—
Of indigo	-	-	-	-	46·606	—
Of tallow	-	-	-	-	38·046	—
Of gum	-	-	-	-	24·683	—
Of brimstone	-	-	-	-	19·801	—
Of whale oil	-	-	-	-	38·818	—

The mean of the above is 38·853 cube feet to a ton; and, indeed, 40 feet is the usual allowance taken by warehousemen, 35 feet being that calculated in shipping.

Sugar in hogsheads will be found to be about 69 cube feet to the ton. Thus, a hogshead 3 ft. 6 in. high, 3 ft. 4 in. diameter at the ends, and 3 ft. 11 in. in the middle, weighs about 15½ cwt.

The following are the usual dimensions and weights of tea in the chests, which, however, are not always uniform:—

	* Dimen- sions.	Cube.	Weight.	Lbs. per Foot Cube.	Cube Feet in a Ton.
Congo -	1 10½	4·403	111 lbs.	25·21	88·87
	1 8½				
	1 4½				
Souchong	1 7½	4·180	108 lbs.	25·84	86·70
	1 7½				
	1 7				
Bohea -	2 9	8·609	224 lbs.	26·02	86·09
	1 10				
	1 8½				
Twankay	1 11½	5·140	104 lbs.	20·23	110·70
	1 6				
	1 8				
Hyson -	1 6½	4·048	80 lbs.	19·76	113·34
	1 6				
	1 9				
The means will be		5·276	-	23·41	97·14

Wheat, taking the average weight of a Winchester bushel at 60 lbs., will give 48·13 cube feet to a ton.

A ton of coals is about 45·3 cubic feet.

In the valuation of leases held on lives, the operation, after bringing the rent to a clear annuity, is conducted by means of the sixth, seventh, and eighth tables, as the case may require.

## GLOSSARY OF TERMS USED BY ARCHITECTS;

ALSO

### A LIST OF THE PRINCIPAL ARCHITECTS

OF ALL TIMES AND COUNTRIES, ALPHABETICALLY ARRANGED,

AND

### A CATALOGUE OF THE MOST USEFUL WORKS ON ARCHITECTURE.

# A.

**ABACISCUS.** A word sometimes used as synonymous with abacus, but more correctly applied to a square compartment enclosing a part or the entire pattern or design of a Mosaic pavement.

**ABACUS.** (Gr. *Ἀβάξ*, a slab.) The upper member of the capital of a column, and serving as a crowning both to the capital and to the whole column. It is otherwise defined by some as a square table, list, or plinth in the upper part of the capitals of columns, especially of those of the Corinthian order, serving instead of a drip or corona to the capital, and supporting the nether face of the architrave, and the whole trabeation. In the Tuscan, Doric, and ancient Ionic orders, it is a flat square member, well enough resembling the original title; whence it is called by the French *tailloir*, that is, a trencher, and by the Italians *credenza*. In the richer orders it parts with its original form, the four sides or faces of it being arched or cut inwards, and ornamented in the middle of each face with a rose or other flower, a fish's tail, &c.; and in the Corinthian and Composite orders it is composed of an ovolo, a fillet, and a cavetto. The word is used by Scamozzi to signify a concave moulding in the capital of the Tuscan pedestal.

**ABATE, NICHOLAS.** See ARCHITECTS, list of, 240.

**ABATON.** (Gr. *Ἀβάρον*, an inaccessible place.) A building at Rhodes, mentioned by Vitruvius, lib. ii., entrance whereof was forbidden to all persons, because it contained a trophy and two bronze statues erected by Artemisia in memory of her triumph in surprising the city.

**ABATTOIR.** (Fr. *Abattre*, to knock down.) A building appropriated to the slaughtering of cattle. See p. 797.

**ABBEY.** (Fr. *Abbaïe*.) Properly the building adjoining to, and near a convent or monastery, for the residence of the head of the house (abbot or abbess). It is often used for the church attached to the establishment, as also for the buildings composing the whole establishment. In such establishments the church was usually grand, and splendidly decorated. They had a *refectory*, which was a large hall in which the monks or nuns had their meals; a *guest hall*, for the reception and entertainment of visitors; a *parlour* or *locutory*, where the brothers or sisters met for conversation; a *dormitory*, an *almonry*, wherefrom the alms of the abbey were distributed; a *library* and *museum*; a *prison* for the refractory, and *cells* for penance. The *sanctuary* was rather a precinct than a building, in which offenders were, under conditions, safe from the operation of the law. *Granges*, or farm buildings, and *abbatial* residences. *Schools* were usually attached for the education of youth, with separate accommodations for the scholars. A *singing school*, a *common room*, with a fire in it, for the brothers or sisters to warm themselves, no other fire being allowed, except in the apartments of the higher officers. A *mint*, for coining, and a room called an *exchequer*. The abbey was always provided with a *churchyard*, a *garden*, and a *bakehouse*. The *sacristy* contained the garments of the priests, and the vessels, &c.; *vestiaria* or wardrobes being assigned for the monks. Many of the ordinary duties of these persons were performed in the cloisters where they delivered their lectures.

**ABELE TREE.** A species of white poplar, enumerated among woods by Vitruvius (book ii.

chap. ix.) as being, in many situations, serviceable from its "toughness," and also from its colour and lightness fitting it for carvings.

**ABREUVOIR.** (Fr.) A watering-place for horses. In masonry it is the joint between two stones, or the interstice to be filled up with mortar or cement, when either are to be used.

**ABSCISS, or ABSCISSA.** (Lat. Ab and Scindo.) A geometrical term, denoting a segment cut off from a straight line by an ordinate to a curve.

**ABSIS.** See **APSIS**.

**ABSTRACT.** A term in general use among artificers, surveyors, &c. to signify the collecting together and arranging under a few distinct heads the various small quantities of different articles which have been employed in any work, and the affixing of a price to determinate portions of each, as per square, per foot, per pound, &c., for the purpose of more expeditiously and conveniently ascertaining the amount. See p. 620, *et seq.*

**ABUSE.** A term applied to those practices in architecture which, arising from a desire of innovation, and often authorised by custom, tend to unfix the most established principles, and to corrupt the best forms, by the vicious way in which they are used. Palladio has given a chapter on them in his work. He reduces them to four principal ones: the first whereof is the introduction of brackets or modillions for supporting a weight; the second, the practice of breaking pediments so as to leave the centre part open; third, the great projection of cornices; and, fourth, the practice of rusticated columns. Had Palladio lived to a later day, he might have greatly increased his list of abuses, as Perrault has done in the following list: the first whereof is that of allowing columns and pilasters to penetrate one another, or be conjoined at the angles of a building. The second, that of coupling columns, which Perrault himself in the Louvre has made almost excusable; the third, that of enlarging the metopæ in the Doric order, for the purpose of accommodating them to the intercolumniations; the fourth, that of leaving out the inferior part of the tailloir in the modern Ionic capital; the fifth, that of running up an order through two or three stories, instead of decorating each story with its own order; the sixth, that of joining, contrary to the practice of the ancients, the plinth of the column to the cornice of the pedestal, by means of an inverted cavetto; the seventh, the use of architrave cornices; the eighth, that of breaking the entablature of an order over a column, &c. &c.

**ABUTMENT.** (According to some, from the French *aboutir*, to *abut*, among whom the learned Spelman; but according to others, from the Saxon *abutan*, *about*.) The solid part of a pier from which the arch immediately springs. Abutments are artificial or natural: the former are usually formed of masonry or brickwork, and the latter are the rock or other solid materials on the banks of the river, in the case of a bridge, which receive the foot of the arch. It is obvious that they should be of sufficient solidity and strength to resist the thrust of the arch. See p. 401, *et seq.*, and **ARCH** in this glossary.

**ABUTTALS.** The buttings or boundings of land.

**ACANTHUS.** (*Ἀκανθός*, a spine.) A spiny herbaceous plant found in various parts of the Levant. Its leaf is said by Vitruvius to have been the model on which the Grecian architects formed the leaves of the Corinthian capital. See p. 61.

**ACER.** (Celt. *Ac*, a point; Lat. *Acer*, sharp.) A genus of trees comprehending the maple and sycamore, the wood whereof is not of much value. That of the *acer campestre* furnishes the cabinet-makers with what they call bird's-eye maple.

**ACCESSES.** See **PASSAGE**.

**ACCIDENTAL POINT.** In perspective, the point in which a straight line drawn from the eye parallel to another straight line cuts the perspective plane. It is the point wherein the representations of all straight lines parallel to the original straight line concur when produced. Its name is adopted to distinguish it from the principal point or point of view.

See **PERSPECTIVE**, p. 649, *et seq.*

**ACOUSTICS.** (Gr. *Ἀκούω*, to hear.) The doctrine or theory of sounds, as applicable to buildings. See p. 801, *et seq.*, **THEATRE**.

**ACROPOLIS.** (Gr. *Ἀκρὸς* and *Πολίς*, city.) The upper town or citadel of a Grecian city, usually the site of the original settlement, and chosen by the colonists for its natural strength. The most celebrated were those of Athens, Corinth, and Ithome, whereof the two latter were called the horns of the Peloponnesus, as though their possession could secure the submission of the whole peninsula.

**ACROTERIA.** (Gr. *Ἀκροτήριον*, the extremity of anything.) The pedestals, often without base or cornice, placed on the centre and sides of pediments for the reception of figures. Vitruvius says that the lateral acroteria ought to be half the height of the tympanum, and the apex acroterium should be an eighth part more. No regular proportion, however, is observable in Grecian buildings.

The word acroterium is applied to the ridge of a building; it has also been used to signify the statues on the pedestals; but it is only to these latter that it is strictly applicable. The word has moreover been given to the small pieces of wall in balus-

trades, between the pedestal and the balusters, and again for the pinnacles or other ornaments which stand in ranges on the horizontal copings or parapets of buildings.

**ACUTE-ANGLED TRIANGLE.** A triangle having all its angles acute. Every triangle has at least two acute angles.

**ACUTE ANGLE.** A term used in geometry to denote an angle less than  $90^\circ$ , that is, less than a right angle.

**ADAM, ROBERT.** See ARCHITECTS, list of, 302.

**ADAMS, ROBERT.** See ARCHITECTS, list of, 244.

**ADHESION** (Lat. *Adhæreo*.) A term in physics denoting the force with which different bodies remain attached to each other when brought into contact. It must not be confounded with cohesion, which is the force that unites the particles of a homogeneous body with each other. The following is an account of some experiments recorded in the *Technical Repository* for 1824. "The insertion of a nail is accomplished by destroying the cohesion of the wood, its extraction by overcoming the force of adhesion and friction. We will consider it here solely as a case of adhesion. Fine sprigs, of which 4560 weighed one pound,  $\frac{1}{16}$  of an inch long, forced four tenths of an inch into dry Christiana deals at right angles to the fibre, required a force of 22 lbs. to extract them. The same description of nail having 3200 in the pound,  $\frac{3}{100}$  of an inch long, and forced  $\frac{1}{10}$  of an inch into the same kind of wood, required 37 lbs. to extract it. Threepenny brads, 618 to the pound weight, one and a quarter inch long, forced half an inch into the wood, required a force of 72 lbs. to draw them out. Fivepenny nails, 139 to the pound weight, two inches long, and forced one inch and a half into the wood, required a force of 170 lbs. to extract them. The same kind of nail forced one inch and a half into the wood required 327 lbs. to draw it out. In this last experiment the nail was forced into the wood by a hammer of cast iron weighing 627 lbs. falling from a height of twelve inches, four blows of which were necessary to force the nail an inch and a half into the wood. It required a pressure of 400 lbs. to force the nail to the same depth. A sixpenny nail driven one inch into dry elm across the grain or fibres required 327 lbs. to draw it out by direct force; driven endwise into dry elm, or parallel with the grain, it required only 257 lbs. to extract it. The same sort of nail driven into dry Christiana deal was extracted by a force equal to 257 lbs., and by one of 87 lbs. from a depth of an inch. The adhesion, therefore, of a nail driven into elm across the grain, or at right angles to the fibres of the wood, is greater than when it is driven with the grain, or parallel with the fibres, in the proportion of 100 to 78, or 4 to 3. And under the same circumstances, in dry Christiana deal, as 100 to 33·8, or nearly 3 to 1. The comparative adhesion of nails in elm and deal is between 2 and 3 to 1. To extract a sixpenny nail driven one inch into green sycamore required 312 lbs.; from dry oak, 507 lbs.; and from dry beech, 667 lbs. A common screw of one fifth of an inch had an adhesion about three times as great as that of a sixpenny nail. A common sixpenny nail driven two inches in dry oak would require more than half a ton to extract it by pressure."

**ADIT** (Lat. *Adeo*), or **ADITUS**. The approach or entrance to a building, &c. Among the ancients the *aditus theatri*, or adits of a theatre, were doorways opening on to the *stairs*, by which persons entered the theatre from the outer *portico*, and thence descended into the seats. Upon the same principle were the adits of a circus.

**ADJACENT ANGLE**, in geometry, is an angle immediately contiguous to another, so that one side is common to both angles. This expression is more particularly applied to denote that the two angles have not only one side in common, but likewise that the other two sides form one straight line.

**ADYTUM.** (Gr. *Ἀδυτον*, a recess.) The secret dark chamber in a temple to which none but the priests had access, and from which the oracles were delivered. Seneca, in his tragedy of *Thyestes* says,—

"Hinc orantibus  
Responsa dantur certa, dum ingenti sono  
Laxantur adyto fata."

Among the Egyptians the *secos* was the same thing, and is described by Strabo. The only well-preserved ancient adytum that has come to our knowledge is in the little temple at Pompeii; it is raised some steps above the level of the temple itself, and is without light.

**ADZE, or ADVICE.** An edged tool used to chip surfaces in an horizontal direction, the axe being employed to chop materials in vertical positions. The blade, which is of iron, forms a small portion of a cylindric surface in both its sides, and has a wooden handle fixed into a socket at one of its extremities, in a radial direction, while the other extremity, parallel to the axis of the cylinder, and therefore at right angles to the handle, is edged with steel, and ground sharp from the concave side. The adze is chiefly employed for taking off thin chips from timber or boards, and for paring away irregularities at which the axe cannot come. It is also used in most joinings of carpentry, particularly when notched upon one another, scarfings, thicknesses of flooring boards opposite to the joints, &c.

**ÆLIFIC.** See ARCHITECTS, list of, 76.

**AERIAL PERSPECTIVE.** The relative apparent recession of objects from the foreground, owing to the quantity of air interposed between them and the spectator. It accompanies the recession of the perspective lines.

**ÆSTHETICS.** (Gr. *Αισθητικός*, having the power of perception by means of the senses.) It is in the fine arts that science which derives the first principles from the effect which certain combinations have on the mind as connected with nature and right reason. See p. 673.

**ÆTHERIUS.** See ARCHITECTS, list of, 60.

**ÆTIAIOL** (Gr. *Aetos*, an eagle.) The name given by the Greek architects to the slabs forming the face of the tympanum of a pediment. This word occurs in the Athenian inscription now in the British Museum, brought to England by Dr. Chandler, and relating to the survey of some temple at Athens.

**ÆTOMA, or ÆTOS.** (Gr. *Aetos*.) A name given by the Greek architects to the tympanum of a pediment. It seems derived from the custom of decorating the apex or ridge of the roof with figures of eagles, and that the name thence first given to the ridge was afterwards transferred to the pediment itself.

**AGAMEDES.** See ARCHITECTS, list of, 3.

**AGAPTOS.** See ARCHITECTS, list of, 10.

**AGNOLO D', BACCIO.** See ARCHITECTS, list of, 206.

**AGNOLO GABRIELLO.** See ARCHITECTS, list of, 171.

**AGOSTINO and ANGELO, of Siena.** See ARCHITECTS, list of, 131.

**AGRICOLA.** See ARCHITECTS, list of, 59.

**AIR DRAINS, or DRY AREAS.** Cavities between the external walls of a building protected by a wall towards the earth, which is thus prevented from lying against the said walls and creating damp. They may be made with the walls battering against the ground, and covered over with paving stones, or with their walls nearly perpendicular, and arched on the top; the bottoms should be paved, and they should be well ventilated.

**AIR HOLES.** Holes made for admitting air to ventilate apartments, also for introducing it among the timbers of floors and roofs for the prevention or destruction of the dry rot.

**AIR TRAP.** A trap immersed various ways in water to prevent foul air rising from sewers or drains.

**AUTAGE.** (Fr.) Part of the apparatus of an artificial fountain, being a sort of *jet d'eau*, or kind of tube fitted to the mouth or aperture of a vessel, through which the water is to be played, and by it determined into the form to be given to it.

**AISLE, or ALA.** (Lat. *Ala*.) A term chiefly used by the English architect to signify the side subdivisions in a church, usually separated from the nave or centre division by pillars or columns; but among different nations, as applied to architecture, it bears different significations. We are told by Strabo that among the Egyptians the *alæ* of the temple were the two walls that enclosed the two sides of the pronaos, and of the same height as the temple itself. The walls, he observes, from above ground, were a little farther apart than the foundations of the temple, but as they rose, were built with an inclination to each other. We do not, however, clearly understand the passage, which puzzled Pocock as much as it has ourselves. The Greek *alæ*, called *ptera*, were the colonnades which surrounded the cell of the temple, the monopteros temple being the only species which had columns without a wall behind them. The peripteral had one tier of columns round the cell, the dipteral two, and the pseudo or false dipteral, invented by Hermogenes, was that in which the *alæ* was single, but occupied the same space on the sides of the cell as the dipteral, though one of the tiers of columns was left out. Thus, by metaphor, the columns were called the *alæ* or wings of the temple. The term is also applied to the sides of a building which are subordinate to the principal and central division, and are vulgarly called wings. In Gothic as well as many modern churches the breadth is divided into three or five parts, by two or by four rows of pillars running parallel to the sides; and as one or other is the case, the church is said to be a three-aisled or five-aisled fabric. The middle aisle is called the nave or chief aisle, and the penthouse, which joins to each side of the main structure containing the aisles, is called a wing. In Great Britain no instance occurs of a five-aisled church, except a building at the west end of the cathedral at Durham. On the Continent there are many such buildings, among which is the cathedral at Milan. It is somewhat remarkable that in Westminster Abbey and in Redcliffe Church at Bristol the aisles are continued on each side of the transept, and in Salisbury Cathedral on one side only, a circumstance not met with in any other churches in this country.

**ALABASTER.** A white semi-transparent variety of gypsum or sulphate of lime, a mineral of common occurrence, and used for various ornamental purposes. It was much used formerly for monuments in churches and the like.

**ALBARIUM OFUS.** (Lat.) In ancient Roman architecture a term imagined by some to have been nothing more than a species of whitewash applied to walls, but, as we think,

incorrectly. In the passage of the tenth chapter of the fifth book of Vitruvius, where he recommends the use of the albarium opus for the ceilings of baths, he allows *tecturium opus* as a substitute; so that we think it was a species of stucco. Its employment at the baths of Agrippa, knowing as we do the extent to which luxury was carried in the baths of the ancients, seems to prove it a superior sort of stucco, and it is by no means improbable that it was susceptible of a high polish.

ALBERT. See ARCHITECTS, list of, 69.

ALBERTI, ARISTOTELE. See ARCHITECTS, list of, 180.

——, LEO BAPT. See ARCHITECTS, list of, 162.

ALCOCK. See ARCHITECTS, list of, 169.

ALCOVE. (Alcoba, Sp.; Elcant, Arab., a sleeping chamber.) That part of a sleeping chamber wherein the bed is placed. The use of alcoves, though not by that name, is ancient. They were frequently designed in the form of a niche; such, for instance, as those that Winkelman notices at Hadrian's villa at Tivoli, of which sort are some at Pompeii. They were often formed by enclosures or balustrades, of various heights, and by means of draperies the part was separated from the large chamber whereof it was a part. Some idea may be formed of it from many of the ancient bassi relievi, especially from the celebrated one known by the name of the *Nozze Aldobrandini*. In modern works this part of a room differs according to the rank and taste of the proprietor. In England it is rarely introduced, but in France and Italy it often forms a beautiful feature in the apartments of palaces.

ALDER. (Ang. Sax. Ellarn.) A tree belonging to the order Betulaceæ. See page 486.

ALDRICH. See ARCHITECTS, list of, 268.

ALDUN. See ARCHITECTS, list of, 79.

ALEOTIL. See ARCHITECTS, list of, 253.

ALESSI. See ARCHITECTS, list of, 215.

ALEATORIUM. In ancient Roman architecture, a room in which games at dice were played.

ALEXANDER. See ARCHITECTS, list of, 90.

ALGARDI. See ARCHITECTS, list of, 256.

ALIPITERION. In ancient Roman architecture, a room used by the bathers for anointing themselves.

ALKORANES. In Eastern architecture, high slender towers attached to mosques, and surrounded with balconies, in which the priests recite aloud at stated times prayers from the Koran, and announce the hours of devotion to worshippers. They much embellish the mosques, and are often very fantastical in form.

ALLEY. (Fr. Allée.) An aisle, or any part of a church left open for access to another part. In towns, a passage narrower than a lane. A walk in a garden.

ALMEHBAB. A niche in the mosques of the Mahometans which points towards the *Kebba*, or temple of Mecca, to which their religion directs them to bow their face in praying.

ALMONRY. Properly a closet or repository for the reception of broken victuals set apart as alms for the poor, but more generally used to denote a house near the church in abbeys or their gates, provided with various offices for distributing the alms of the convent and for the dwelling of the almoner.

ALMHOUSE. A house devoted to the reception and support of the poor, generally endowed for a particular description of persons.

ALOISIUS. See ARCHITECTS, list of, 56.

ALONSO. See ARCHITECTS, list of, 196.

ALTAR. (Lat. Altare.) A sort of pedestal whereon sacrifice was offered. According to Servius there was among the ancients a difference between the *ara* and *altare*, the latter being raised upon a substruction, and used only in the service of the celestial and superior divinities, whereas the former was merely on the ground, and appropriated to the service of the terrestrial gods. Altars to the infernal gods were made by excavation, and termed *scrobiculi*. Some authors have maintained that the *ara* was the altar before which prayers were uttered, and that the *altare* was used for sacrifices only. There is however from ancient authors no appearance of such distinctions, but that the words were used indiscriminately. The earliest altars were square polished stones, on which were placed the offerings to the gods. Whilst the sacrifice consisted only of libations, perfumes, and offerings of that nature, the altar was small, and even portable; when man, however, began to consider he was honouring the divinity by an offering of blood, the altar necessarily expanded in dimensions. Different forms of it were adopted, according to the nature of the sacrifice, and on it the throat of the victim was cut and the flesh burnt. Of this sort is the circular altar of the Villa Pamphili at Rome, one of the largest and most elegant of the class. On it appears the cavity for holding the fire, and the grooves for carrying off the blood. The varieties of altars were suitable in form, ornament, and situation to the service to which they were appropriated: some, as we have already observed, being for sacrifices of blood, others for receiving offerings

and the sacred vessels; some for burning incense, others for receiving libations. Many were set up as mere monuments of the piety of a devotee, whilst others were raised to perpetuate some great event. They served for adjuration as well as for an asylum to the unfortunate and evil doer. In form they varied from square to oblong, and from triangular to circular. Those of metal were commonly tripodial. When of brick or stone their plan is generally square. According to Pausanius they were occasionally made of wood. They do not appear to have been of any regular standard height, for they are sometimes found on bassi rilievi reaching but little above a man's knee, whereas in others they appear to reach his middle; but it seems that in proportion to its diameter the circular altar was generally the highest. Vitruvius says that they should not be so high as to intercept the statues of the gods, and he gives the relative heights of those used for different divinities. Thus, he says, those of Jupiter and the celestial gods are to be the highest; next, those of Vesta and the terrestrial gods; those of the sea gods are to be a little lower, and so on. On festivals they were decorated with such flowers and leaves as were sacred to the particular divinity. But besides this casual decoration, the ancient altars furnish us with some of the most elegant bassi rilievi and foliage ornaments that are known. According to Vitruvius, their fronts were directed towards the east, though very frequently but little regard was paid to their position, as they were occasionally placed under the peristyle of a temple, and not unfrequently in the open air. In the larger temples were often three different altars. The first was in the most sacred part, in front of the statue of the god; the second before the door of the temple; and the third (called *ancalabris*) was portable, and on it the offerings and sacred vessels were placed.

The altars of the Catholic church are either attached or isolated. The former generally stand against a wall, and are so decorated as to appear quite independent of it. The decorations are either of painting or sculpture, or both. The isolated altar has no sort of connection with any part either of the building or of its decorations. The high altar is always isolated, whether placed at the end of the church or in its centre. Whatever the situation of the high altar, it should be grand and simple: it should be raised on a platform, with steps on every side. The table itself is usually in the form of an antique sarcophagus. The altar of the Protestant churches of England is generally only an oak table, covered with a white cloth, and but little ornamented either above or on the sides. In country churches we sometimes find superadded as an ornament, to show, we suppose, that painting may be tolerated in Protestant worship, the figures

"Of Moses and Aaron stuck close by the wall,  
To hold the commandments for fear they should fall."

The fact is, the Church of England is so overawed by sectaries, that she is afraid of doing anything congenial to the feelings of a polished mind as respects the decoration of her churches, which are in the new examples built by the commissioners more than ever stripped of all elegant accompaniments; a practice which turns our churches into barns rather than temples of the Most High.

The altars of the Greek church, though in other respects the religion vies in splendour with the Romish church, are destitute of painted or sculptured ornament; and in Calvinistic churches the name as well as the uses of an altar are unknown either as an appendage or a decoration.

**ALTAR-PIECE.** The entire decorations of an altar.

**ALTAR SCREEN.** The back of an altar, or the partition by which the choir is separated from the presbytery and Lady chapel. The date of its introduction into English churches we believe to have been about the close of the thirteenth century. It is generally of stone, and composed of the richest tabernacle work, of niches, finials, and pedestals, supporting statues of the tutelary saints. Those to the high altars of Winchester Cathedral, of St. Alban's Abbey, and of New College, are fine examples. Many were destroyed at the Reformation, or filled up with plaster and covered with wainscot. In all altar screens a door is placed on each side for the officiating priests, whose vestments were deposited in an apartment behind the altar screen.

**ALTO RILIEVO.** See RILIEVO.

**ALYPIUS.** See ARCHITECTS, list of, 53.

**AMBITUS.** A space which surrounded a tomb, and was held sacred. In descriptions of subterranean tombs, it denoted a small niche made in the wall for the reception of an urn or body. When the corpse was placed in it, to the mouth of the niche a slab was fixed, so fitted and cemented as to prevent noisome effluvia. The slabs were sometimes inscribed with the name and quality of the party. If they received an urn, either upon that or over the niche the inscription was placed. Much decoration was occasionally used in the recesses themselves.

**AMBO.** (Gr. *ἀμβων*.) The elevated place or pulpit in the early Christian churches, which, according to Ciampini, fell into disuse about the beginning of the fourteenth century.

The last erected ambo in Rome is supposed to have been that of S. Pancrazio, on which appears the date of 1249. It was an oblong enclosure, with steps usually at the two ends. Two ambones are described by Eustace in the cathedral at Salerno. They are placed on each side of the nave before the steps of the chancel. They are both of marble, and the largest is covered with mosaic and supported by twelve Corinthian granite columns.

**AMBULATORY.** (Lat.) A sheltered place for exercise in walking; a cloister; a gallery.

**AMBULATIO.** (Lat.) See **PTEROMA**.

**AMMANATI.** See **ARCHITECTS**, list of, 239.

**AMPHIPROSTYLE.** (Gr. *αμφι*, both or double, *προ*, before, *στυλος*, a column.) A term applied to a temple having a portico or porch in the rear as well as in the front, but without columns at the sides. This species of temple never exceeded the use of four columns in the front and four in the rear. It differed from the temple in *antis*, in having columns instead of *antæ* at the angles of the portico. See **TEMPLE**.

**AMPHITHEATRE.** (Gr. *αμφι*, about, and *θεατρον*, a theatre.) An edifice formed by the junction of two theatres at the proscenium, so as to have seats all round the periphery, a contrivance by which all the spectators, being ranged about on seats rising the one above the other, saw equally well what passed on the arena or space enclosed by the lowest range of seats, whose wall towards the arena was called the *podium*. The origin of the amphitheatre seems to have been among the Etruscans, to whom also are attributed the first exhibitions of gladiatorial fights. It was from this people that the Romans acquired a taste for such shows, which they communicated to every nation which became subject to their dominion. Athenæus says, "Romani ubi primum ludos facere cœperunt, huic asciti artifices ab Etruscis civitatibus fuerunt, sero autem ludi omnes qui nunc a Romanis celebrari solent sunt instituti." Lib. iv. c. 17. The most extraordinary edifice remaining in Rome, we may indeed say in the world, is the amphitheatre generally called the Coliseum. It was commenced by Vespasian, and completed by Titus his son. Words are inadequate to convey a satisfactory idea of its stupendous and gigantic dimensions. Ammianus says that it was painful to the eye to scan its summit: "ad eujus summitem ægrè visio humana conscendit." Martial, in one of his epigrams, says,

"Omnis Cæsareo cedat labor amphitheatro,  
Unum pro cunctis fama loquatur opus."

The greater axis of the ellipsis on which it is planned is about 627 feet, and the lesser 520 feet, the height of the outer wall about 166 feet, such wall being decorated by the Doric, Ionic, and Corinthian Orders, and pierced with arcades between the columns. Covering five English acres and a quarter, it had seats for 87,000 spectators with standing room for 22,000 others. It has suffered much from having been used actually as a quarry for many of the modern edifices of the city; but in the present day its preservation is strictly attended to by the papal government. A description of this building has been given in p. 94, *et seq.* Besides the Coliseum, there were three other amphitheatres in Rome: the Amphitheatrum Castrense, on the Esquiline, built probably by Tiberius; that of Statilius Taurus, and that built by Trajan in the Campus Martius. The other principal amphitheatres were those of Otricoli on the Garigliano, of brick; Puzzuoli, Capua, Verona, at the foot of Monte Casino, Pæstum, Syracuse, Agrigentum, Catania, Argos, Corinth, Pola in Istria (see *fig.* 127.), Hipella in Spain, Nismes, Arles, Frejus, Saintes, and Autun. This last has four stories, in that respect like the Coliseum. That which remains in the most perfect condition is at Verona; its age has not been accurately determined, some placing it in the age of Augustus, and others in that of Maximian; of these, Maffei thinks the first date too early, and the latter too late. The silence of Pliny upon it seems to place it after the time of his writing. In the reign of Gallienus, it was not only built, but began to suffer from dilapidation, for many of the stones belonging to it are found in the walls of Verona, which walls were erected in the time of that emperor. Many of these were keystones, and the numbers cut upon them still remain. From the silence of authors that it was the work of any of the emperors, it seems probable that, like that at Capua, it was erected at the expense of the citizens. The length is about 514 feet, and the breadth about 410; the long diameter of the arena 242 feet, the short diameter 147 feet. The audience part or *visorium* contained forty-seven tiers of seats, and the building was capable of containing about 22,000 seated spectators. In the profile of the walls of this amphitheatre the diminution in thickness upwards is made on the inside, which is also the case in that at Pola. In the Coliseum, the diminution is on the outside. The amphitheatre at Nismes contained about 17,000 persons, and was about 400 feet in length and 320 feet in breadth.

The first amphitheatres, as we learn from Pliny, were constructed of wood, and usually placed in the Campus Martius, or in some place out of the city. Accidents occurring from their insecurity, they were abandoned for the more substantial species of fabric whereof we have been speaking. The first person who is said to have erected an amphi-

theatre in Rome was Caius Scribonius Curio, on the occasion of the games he gave to the people at the funeral obsequies of his father. Determined to surpass all that had hitherto been seen, he constructed two theatres of wood, back to back, which, after the theatrical representations had been finished, were turned round with the spectators in them, leaving the stages and scenery behind. By their opposite junction, they formed a perfect amphitheatre, in which the people were gratified with a show of gladiators.

The part in which the gladiators fought was called the *arena*, from being usually covered with sand to absorb the blood spilt in the conflicts, for which it was used. It was encompassed by a wall called the *podium*, fifteen or sixteen feet high, immediately round which sat the senators and ambassadors. As in the theatres, the seats rose at the back of each other; fourteen rows back from the podium all round being allotted to the equites, and the remainder to the public generally, who sat on the bare stone, cushions being provided for the senators and equites. Though at most times open to the sky, there were contrivances for covering the whole space with an awning. The avenues by which the people entered and retired were many in number, and were called *vomitoria*. The reader who wishes for further information on this subject may consult with advantage Maffei, *Degli Anfiteatri*, and the section on amphitheatres in his excellent and learned work, *Verona illustrata*.

**ANAMORPHOSIS.** (Gr. *ana*, backward, and *μορφη*, form.) A term employed in perspective to denote a drawing executed in such a manner that when viewed in the common way it presents a confused and distorted image of the thing represented, or an image of something entirely different; but when viewed from a particular point, or as reflected by a curved mirror, or through a polyhedron, it recovers its proportions and presents a distinct representation of the object.

**ANCHOR.** In decoration, an ornament shaped similarly to an anchor or arrow head. It is used with the egg ornament (see page 684. *fig. 86.*) to decorate or enrich mouldings. By some it is called a tongue, from its supposed resemblance to the forked tongue of a serpent. It is used in all the orders, but only applied to the moulding called the echinus or quarter round.

**ANCONES.** (Gr. *γκων*, the joint of the elbow.) The trusses or consoles sometimes employed in the dressings or antepagments of apertures, serving as an apparent support to the cornice of them at the flanks. In ancient doors the ancones were sometimes broader at the top than at the bottom, and were not in contact with the flanks of the architrave, but situated a small distance from them. The term is also used to signify the corners or quoins of walls, cross beams, or rafters.

**ANDREA DI PISA.** See ARCHITECTS, list of, 130.

**ANDRON.** (Gr. *ανδρ.*) In ancient architecture, the apartment appropriated to the reception of the male branches of the establishment, and always in the lower part of the house, the *gynæcia*, or women's apartments, being in the upper part.

**ANDRONICUS.** See ARCHITECTS, list of, 23.

**ANDROUET DU CÉRCEAU.** See ARCHITECTS, list of, 246.

**ANGLE.** (Lat. *Angulus*.) The mutual inclination of two lines meeting in a point, called indifferently the angular point, vertex, or point of concurrence: the two lines are called legs. See GEOMETRY, page 306.

**ANGLE BAR.** In joinery, the upright bar at the angle of a polygonal window.

**ANGLE BEAD, or STAFF BEAD.** A vertical bead, commonly of wood, fixed to an exterior angle and flush with the intended surface of the plaster on both sides, for the purpose of securing the angle against accident, serving also as a guide for floating the plaster. The section of these beads is about three quarters of a circle, with a projecting part from the other quarter, by means whereof they are made fast to the wood bricks, plugging, or bond timbers. Angle beads of wood round the intradoses of circular arches are difficult to bend without cutting or steaming them. The former has a very unsightly appearance, and the latter method is at once inconvenient and troublesome. The plaster itself is the best material in this case, and at the height generally placed will be out of the reach of accident. In good finishings corner beads which are unsightly should not be used, but the plaster should be well gauged and brought to an arris.

**ANGLE BRACE.** In carpentry, a piece of timber fixed to the two extremities of a piece of quadrangular framing, making it partake of the form of an octagon. This piece is also called an *angle tie* and a *diagonal tie*. By the use of this piece wall plates are frequently braced. In constructing a well hole of a circular section through a roof or floor for a skylight, &c. the framing is first made in a quadrangular form; braces are then fixed opposite to each angle, and the aperture becomes an octagon; finally, pieces are fixed at each angle of the octagon, meeting each other in the middle of its sides, so as to transform the section of the aperture into a circle.

**ANGLE BRACKET.** A bracket placed in the vertex of an angle, and not at right angles with the sides. See BRACKETING.

**ANGLE CAPITAL.** In ancient Greek architecture, the Ionic capitals used to the flank

- columns which have one of their volutes placed at an angle of  $135^{\circ}$  with the planes of the front and returning frieze. As an example may be given the angle capitals of the temple of Minerva Polias at Athens. This term is also applied to the modern Ionic capital, in which the whole of the four volutes have an angular direction.
- ANGLE CHIMNEY.** A chimney placed in the angle of a room.
- ANGLE MODILLION.** A modillion placed in a direction parallel to a diagonal drawn through a cornice at its mitring. It is an abuse seen only in the buildings erected during the decline of the Roman architecture, as in the ruins of Balbec and Palmyra, and in the palace of the Emperor Dioclesian at Spalatro.
- ANGLE OF VISION.** (See *PERSPECTIVE*, p. 649, *et seq.*) The angle under which an object or objects are seen, and upon which their apparent magnitudes depend. In practical perspective it should not exceed sixty degrees.
- ANGLE OF A WALL.** The angle contained by the vertical planes of two walls which form the angle of the building. The term is sometimes used to denote the line in which the two sides of the angle meet, which by workmen is commonly called the *arris*: the *arris* however is not the angle, but the line of concurrence formed by the two sides or planes which contain the angle.
- ANGLE RAFTER.** The piece of timber in a hipped roof placed in the line of concurrence of the two inclined planes forming the hip. It is more often called a hip rafter. See *HIP* and *CARPENTRY*, page 548.
- ANGLE RIB.** A piece of timber of a curved form placed between those two parts of a coved or arched ceiling or vault which form an angle with each other so as to range with the common ribs on each side or return part.
- ANGLE STAFF.** See *ANGLE BEAD*.
- ANGLE STONES.** A term used by some authors to denote *quoins*.
- ANGLE TIE.** See *ANGLE BRACE*.
- ANGULAR CAPITAL.** See *CAPITAL*.
- ANNUITIES.** See p. 856, *et seq.*
- ANNULAR MOULDINGS.** Generally those having vertical sides and horizontal circular sections.
- ANNULAR VAULT.** A vault springing from two walls each circular on the plan; such as that in the temple of Bacchus at Rome.
- ANNULET.** (Lat. *Annulus*.) A small fillet whose horizontal section is circular. The neck or under side of the Doric capital is decorated with these thin fillets, listels, or bands, whose number varies in different examples. Thus in the Doric of the theatre of Marcellus there are three, whilst in the great temple at Pæstum they are four in number, and in other cases as many as five are used.
- ANTA, æ, plur.** (Lat. *Anta*.) The joints or square posts supporting the lintels of doors. The term *antæ* we think only applicable to pilasters or pillars attached to a wall, though some authors, as Peralut, have thought otherwise. Vitruvius calls square pilasters when insulated *parastatæ*. There are three kinds of *antæ*: those of porches or jamb ornaments; angular *antæ*, being such as show two faces on the walls of a temple; and those on the longitudinal walls of its cell. *Antæ* are only found in temples as wings to the ends of the walls of the pronaos to give a finish to the terminations the ends of the walls would otherwise present. It might have been this view which led the Greeks to treat them rather as distinct objects than to assimilate their finishings to those of columns. Considered as pilasters, the reader is referred to p. 735, *et seq.*, where the diminutions and capitals are fully considered. The latter were never made by the Greeks like those of the accompanying columns. The pilasters in Roman architecture differ only from the column in being square instead of round. A rule in the use of *antæ* was, that their projection should always be equal to that at least of the mouldings used on them. Some beautiful examples of *antæ* capitals exist in the temple of Minerva Polias and the temple of Apollo Didymæus in Ionia.
- ANTE-CHAMBER or ANTE-ROOM.** An apartment through which access is obtained to another chamber or room. One in which servants wait and strangers are detained till the person to be spoken with is at leisure. In the distribution of many houses the peculiarity of the plan forces upon the architect the introduction of ante-rooms: in most cases, indeed, they add both elegance and dignity to a design.
- ANTEPAGMENTA.** (Lat.) In ancient architecture, the jambs or moulded architraves of a door. The lintel returning at the ends with similar mouldings down upon the antepagmenta was called *supercilium*.
- ANTERIDES.** In ancient architecture, buttresses or counterforts for the support of a wall. The Italians call them *speroni* (spurs).
- ANTHEMIUS.** See *ARCHITECTS*, list of, 61.
- ANTE-COUR.** A French term, sometimes however used by English authors. It is the approach to the principal court of a house, and very frequently serves for communication with the kitchen, cellar, stables, &c.

**ANTICUM.** (Lat.) A porch to a front door, as distinguished from *posticum*, which is the porch to a door in the rear of a building. It was the space also between the front columns of the portico and the wall of the cellar. The word has been sometimes improperly used for *anta*.

**ANTIFIXÆ.** (Lat. *anti* and *figo*.) The ornaments of lions' and other heads below the eaves of a temple, through perforations in which, usually at the mouth, the water is cast away from the eaves. By some this term is used to denote the upright ornaments above the eaves in ancient architecture, which concealed the ends of the *harmoni* or joint tiles.

**ANTIQUE.** A term applied to pieces of ancient art by the Greeks and Romans of the classical age.

**ANTIQUARIUM.** Among the ancients an apartment or cabinet in which they kept their ancient books and vases.

**ANTISTATES.** See **ARCHITECTS**, list of, 15.

**ANTONINUS.** See **ARCHITECTS**, list of, 50.

**ANTONIO, FIORENTINO.** See **ARCHITECTS**, list of, 228.

**ANTOINE.** See **ARCHITECTS**, list of, 306.

**APARTMENT.** (Lat. *partimentum*.) A space enclosed by walls and a ceiling, which latter distinguishes it from a court or area. The distribution of apartments of a building has already been treated of in this work. See p. 771, *et seq.*

**APERTURE.** (Lat. *aperio*.) An opening through any body. In a wall it has usually three straight sides, two whereof are perpendicular to the horizon, and the third parallel to it, connecting the lower ends of the vertical sides. The materials forming the vertical sides are called *jambes*, and the lower level side is called the *sill*, and the upper part the *head*. This last is either a curved or flat arch. Apertures are made for entrance, light, or ornament. In Greek and Egyptian architecture, but especially in the latter, the jambes incline towards each other. Sometimes apertures are made circular, elliptical, or portions of those figures. "Apertures," says Sir Henry Wotton, "are inlets for air and light; they should be as few in number, and as moderate in dimensions, as may possibly consist with other due respects; for, in a word, all opening are weakenings. They should not approach too near the angles of the walls; for it were indeed a most essential solecism to weaken that part which must strengthen all the rest."

**APIARY.** (Lat. *apis*.) A place for keeping beehives. Sometimes this is a small house with openings for the bees in front, and a door behind, which is kept locked for security. Sometimes it is an area wherein each particular beehive is chained down to a post and padlocked.

**APODYTERIUM.** (*ἀποδυσθαι*, Gr., to strip oneself.) The apartment at the entrance of the ancient baths, or in the *Palæstra*, where a person took off his dress, whether for bathing or gymnastic exercises. In the baths of Nero, these apartments were small, but in those of Caracalla the apodyterium was a magnificent room with columns and other decorations.

**APOPHYGE.** (Gr., signifying flight.) That part of a column between the upper fillet or amulet on the base and the cylindrical part of the shaft of a column, usually moulded into a hollow or cavetto, out of which the column seems as it were to fly or escape upwards. The French call it *comgé*, as it were, leave to go.

**APOLLODORUS.** See **ARCHITECTS**, list of, 47.

**APOTHECA.** (Gr.) A storehouse or cellar in which the ancient Greeks deposited their oil, wine, and the like.

**APRON, OR PITCHING PIECE.** An horizontal piece of timber, in wooden double-flighted stairs, for supporting the carriage pieces or rough strings and joistings in the half spaces or landings. The apron pieces should be firmly wedged into the wall. See **STAIRCASES**, p. 575, *et seq.*

**APsis, or ABSIS.** (Gr., signifying an arch.) A term in ecclesiastical architecture, denoting that part of the church wherein the clergy was seated or the altar placed. It was so called from being usually domed or vaulted, and not, as Isidorus imagines, from being the lightest part (*apta*). The apsis was either circular or polygonal, and domed over; it consisted of two parts, the altar and the presbytery or sanctuary. At the middle of the semicircle was the throne of the bishop, and at the centre of the diameter was placed the altar, towards the nave, from which it was separated by an open balustrade or railing. On the altar was placed the ciborium and cup. The throne of the bishop having been anciently called by this name, some have thought that thence this part of the edifice derived its name; but the converse is the fact. The *apsis gradata* implied more particularly the bishop's throne being raised by steps above the ordinary stalls. This was sometimes called *exedra*, and in later times *tribune*.

**AQUEDUCT.** (Lat. *aquæ ductus*.) A conduit or channel for conveying water from one place to another, more particularly applied to structures for the purpose of conveying the water of distant springs across valleys, for the supply of large cities. The largest and most magnificent aqueducts with the existence of which we are acquainted were constructed by

the Romans, and many of their ruins in Italy and other countries of Europe still attest the power and industry of that extraordinary nation. The most ancient was that of Appius Claudius, which was erected in the 442d year of the city, and conveyed the Aqua Appia to Rome, from a distance of 11,190 Roman paces (a pace being 58·219 English inches), and was carried along the ground, or by subterranean lines, about 11,000 paces, about 190 of which were erected on arches. The next, in order of time, was the Anio Vetus, begun by M. Curius Dentatus, about the year of Rome 481. The water was collected from the springs about Tivoli; it was about 43,000 paces in length. In the 608th year of the city, the works of the Anio Vetus and Aqua Appia had fallen into decay, and much of the water had been fraudulently abstracted by individuals, the prætor Martius was therefore empowered to take measures for increasing the supply. The result of this was the Aqua Martia, the most wholesome water with which Rome was supplied. It was brought from the neighbourhood of Subiaco, twenty miles above Tivoli, and was 61,710 Roman paces (about 61 miles), whereof 7463 paces were above ground, and the remainder under ground. A length of 463 paces, where it crossed brook and valleys, was supported on arches. To supply this in dry seasons, was conducted into it another stream of equal goodness by an aqueduct 800 paces long. About nineteen years after this was completed, the Aqua Tepula was brought in, supplied also from the Anio; but not more than 2000 paces in length. In the reign of Augustus, Agrippa collected some more springs into the Aqua Tepula, but the latter water flowing in a separate channel, it preserved its name. This was 15,426 paces long, 7000 above ground, and the remainder of the length on arcades. To this was given by Agrippa the name of Aqua Julia. In the year 719 of the city, Agrippa restored the dilapidated aqueducts of Appius, of Martius, and of the Anio Vetus, at his own expense, besides erecting fountains in the city. The Aqua Virgo, which received its name from a girl having pointed out to some soldiers the sources of the stream from which it was collected, was brought to Rome by an aqueduct 14,105 paces in length, 12,865 whereof were underground, and 700 on arches, the remainder being above ground. The Aqua Alsietina, called also Augusta, was 22,172 paces from its source to the city, and 358 paces of it were on arcades. The seven aqueducts above mentioned being found, in the time of Caligula, unequal to the supply of the city, this emperor, in the second year of his reign, began two others, which were finished by Claudius, and opened in the year of the city 803. The first was called Aqua Claudia, and the second Anio Novus, to distinguish it from one heretofore mentioned. The first was 46,406 Roman paces, of which 10,176 were on arcades, and the rest subterranean. The Anio Novus was 58,700 paces in length, 9400 whereof were above ground, 6491 on arches, and the rest subterranean. Some of the arches of these are 100 Roman feet high. All the aqueducts we have mentioned were on different levels, and distributed accordingly to those parts of the city which suited their respective elevations. The following is the order of their heights, the highest being the Anio Novus, 159 feet above level of Tiber: Aqua Claudia, 149 feet; Aqua Julia, 129 feet; Aqua Tepula, Aqua Martia, 125 feet; Anio Vetus, Aqua Virgo, 34 feet; Aqua Appia, 27 feet; and the Aqua Alsietina on the lowest level. The Tiber at Rome being 91·5 feet above the level of the Mediterranean, the mean fall of these aqueducts has been ascertained to be about 0·132 English inches for each Roman pace (58·219 English inches), or 1 in 441. Vitruvius directs a fall of 1 in 200, but Scamozzi says the practice of the Romans was 1 in 500. The quantity of water furnished by six of the aqueducts, as given by Frontinus from a measurement at the head of each aqueduct, is as follows:—

Anio Vetus	-	-	-	-	4398	quinariæ.
Aqua Martia	-	-	-	-	4690	
Aqua Virgo	-	-	-	-	2524	
Aqua Julia	-	-	-	-	1368	
Aqua Claudia	-	-	-	-	4607	
Anio Novus	-	-	-	-	4738	

The whole supply is given as 14,018 quinariæ, after much fraudulent diversion of the water by individuals; but the diminished quantity is supposed to have been 27,743,100 English cubic feet, or, estimating the population of Rome at one million of inhabitants, 27·74 cubic feet per diem for each inhabitant.

The aqueducts required constant repairs, from the nature of their construction, especially those on arches. The spaces between the piers varied much in width, and necessarily in height. Some of the arcades are as much as 27 feet in diameter.

There are remains of Roman aqueducts in other parts of Europe, even more magnificent than those we have mentioned. One, or the ruins of one, still exists at Metz, and another at Segovia in Spain, with two rows of arcades, one above the other. This last is about 100 feet high, and passes over the greater part of the houses of the city. The most remarkable aqueduct of modern times was that constructed by the order of Louis XIV. for conveying the waters of the Eure to Versailles. It is 4400 feet in length, and

## LIST OF ARCHITECTS.

BEFORE CHRIST.			
No. in Gloss.	Name of Architect.	Century.	Principal Works.
17	Archias of Corinth.	5th.	Many temples and other edifices, at Syracuse.
18	Callias of Aradus.	—	Temples, &c., at Rhodes.
19	Ayclius of Aradus.	—	Temple of the Ionian Æsculapius.
20	Mnesthes.	—	Temple of Apollo at Magnesia.
21	Cleomenes of Athens.	4th.	Plan of the city of Alexandria in Egypt.
22	Dinocrates of Macedonia.	—	Rebuilt the temple of Diana at Ephesus; engaged on works at Alexandria; was the author of the proposition to transform Mount Athos into a colossal figure.
23	Andronicus of Athens.	—	Tower of the Winds at Athens.
24	Callimachus of Corinth.	—	Reputed inventor of the Corinthian order.
25	Sostratus of Gnidus.	—	The Pharos of Alexandria.
26	Philo of Athens.	—	Enlarged the arsenal and the Piræus at Athens; erected the great theatre, rebuilt by order of Adrian.
27	Eupolemus of Argos.	—	Several temples and a theatre at Argos.
28	Phæax of Agrigentum.	3d.	Various buildings at Agrigentum.
29	Cossutius of Rome.	2d.	Design for the temple of Jupiter Olympius at Athens.
30	Hermodorus of Salamis.	—	Temple of Jupiter Stator in the Forum at Rome; temple of Mars in the Circus Flaminius.
31	Caius Mutius of Rome.	—	Temple of Honour and Virtue near the trophies of Marius at Rome.
32	Valerius of Ostia.	—	Several amphitheatres with roofs.
33	Batrachus of Laconia.	1st.	These two architects built several temples at Rome. The name of the first ( <i>βατραχος</i> ), signifies a frog; and that of the latter ( <i>σαυρος</i> ) a lizard; and they perpetuated their names on some of the works by the allegorical representation of these two animals sculptured upon them. The churches of St. Eusebius and of St. Lorenzo fuori le Mura, at Rome, still contain some columns whose pedestals are sculptured with a lizard and a frog.
34	Saurus of Laconia.	—	
35	Dexiphanes of Cyprus.	—	Rebuilt the Pharos at Alexandria, at the command of Cleopatra, the other having fallen down.
36	Cyrus of Rome.	—	Architect to Cicero.
37	Postumius of Rome.	—	Many works at Rome and Naples.
38	Corceius Auctus of Rome.	—	Grotto of Puzzuoli; grotto of Cumæ, near the lake now called Lago d'Averno.
39	Fussitius of Rome.	—	Several buildings at Rome; the first Roman who wrote on architecture.
AFTER CHRIST.			
No. in Gloss.	Name of Architect.	Century.	Principal Works.
40	Vitruvius Pollio of Fano.	1st.	Basilica Justitiæ at Fano. A great writer on architecture.
41	Vitruvius Cerdo of Verona.	—	Triumphal arch at Verona.
42	Celer and	—	Golden house of Nero.
43	Severus of Rome.	—	

## LIST OF ARCHITECTS.

AFTER CHRIST.			
No. in Gloss.	Name of Architect.	Century.	Principal Works.
44	Rabirius of Rome.	1st.	Palace of Domitian on Mount Palatine.
45	Mustius of Rome.	—	Temple of Ceres at Rome.
46	Frontinus of Rome.	2d.	He has left a work on aqueducts.
47	Apollodorus of Damascus.	—	Forum Trajani at Rome; a bridge over the Danube in Lower Hungary.
48	Lacer of Rome.	—	A bridge over the Tagus in Spain: a temple now dedicated to San Giuliano.
49	Detrianus of Rome.	—	Moles Hadriani and the Pons Aelius; now called the Castello and Ponte Sant' Angelo.
50	Antoninus, the Senator, of Rome.	—	Pantheon at Epidaurus; baths of Æsculapius.
51	Nicon of Pergamus.	—	Several fine works at Pergamus.
52	Metrodorus of Persia.	4th.	Many buildings in India, and some at Constantinople. The first known Christian architect.
53	Alypius of Antioch.	—	Employed by Julian to lay the foundation of a new temple at Jerusalem.
54	Cyriades of Rome.	5th.	A church and bridge.
55	Sennamar of Arabia.	—	Sedir and Khaovarnack, two celebrated palaces in Arabia.
56	Aloisius of Padua.	—	Assisted in the erection of the celebrated rotunda at Ravenna, the cupola of which is said to have been of one stone, 38 feet in diameter, and 15 feet thick.
57	St. Germain, bishop of Paris, of France.	6th.	Plan of the church of St. Germain at Paris, previously dedicated to St. Vincent; convent at St. Mans.
58	St. Avitus, bishop of Clermont, of France.	—	Church of Madonne du Port.
59	St. Agricola, bishop of Chalons, of France.	—	Cathedral of Chalons, with many other churches in his diocese.
60	Ætherius of Constantinople.	—	Part of the imperial palace, called Chalcis, at Constantinople.
61	Anthemius of Tralles, of Lydia.	—	St. Sophia at Constantinople.
62	Isidorus of Miletus.	—	Assisted Anthemius in the erection of the church of St. Sophia.
63	Chryses of Dara, of Persia.	—	Constructed the celebrated dykes along the Euripus, near Dara, to keep the river in its channel, and to keep out the sea. He was particularly excellent in hydraulic architecture.
64	Isidorus of Byzantium.	7th.	The city of Zenobia in Syria was the work of these two architects.
65	Johannes of Miletus.	—	
66	Saxulphus, abbot of Peterborough, afterwards made bishop of Lichfield, of England.	—	Built the monastery of Médeschampstede, afterwards called Peterborough.
67	Biscopius, Benedict, of England.	8th.	Conventual church of Wearmouth.
68	Egbert, archbishop of York, of England.	—	Rebuilt York Cathedral.
69	Albert, archbishop of York, of England.	—	Completed the building of York Cathedral under Egbert.
70	Eaubald, archbishop of York, of England.	—	Superintended the erection of York Cathedral, under his predecessor, Archbishop Albert.

## LIST OF ARCHITECTS.

AFTER CHRIST.			
No. in Gloss.	Name of Architect.	Century.	Principal Works.
71	Romualdus of France.	9th.	The cathedral of Rheims, the earliest example of Gothic architecture.
72	Tietland of Switzerland.	10th.	Convent of Einsidlen in Switzerland.
73	Tioda of Spain.	—	The palace of King Alphonso the Chaste, at Oviedo, now the episcopal palace ; churches of St. Salvador, St. Michael, and St. Mary.
74	Ednoth, a monk of Worcester, of England.	—	Superintended the erection of the church and conventual offices of Rumsey Abbey.
75	Dunstan, archbishop of Canterbury, of England.	—	Built for himself a cell at Glastonbury Abbey, and was skilful in mechanics.
76	Ælfric, bishop of Crediton, of England.	—	Built part of Malmsbury Abbey Church, in the reign of Edgar.
77	Elphage, bishop of Winchester, of England.	—	Crypts of Winchester Cathedral.
78	Buschetto of Dulichium.	—	The cathedral or duomo of Pisa, the earliest example of the Lombard ecclesiastical style of architecture. It was built in 1016.
79	Aldhun, bishop of Durham, of England.	—	First cathedral church at Durham.
80	Pietro di Ustamber of Spain.	—	Cathedral of Chartres.
81	Lanfranc, archbishop of Canterbury, of England.	—	Choir of Canterbury Cathedral, burnt in 1174.
82	Remigius, bishop of Lincoln, of England.	11th.	Part of Lincoln Cathedral.
83	Carilepho, bishop of Durham, of England.	—	Began the cathedral church of Durham, on a plan which he had brought with him from France, when he was abbot of St. Vincent's in Normandy.
84	Walkelyn, bishop of Winchester, of England.	—	Said to have erected the oldest part of Winchester Cathedral.
85	Harlewin, abbot of Glastonbury, of England.	—	Rebuilt the abbey church of Glastonbury.
86	Mauritius, bishop of London, of England.	12th.	Built old St. Paul's, in 1033.
87	Gundulf, bishop of Rochester, of England.	—	Rochester Castle ; White Tower of the Tower of London ; rebuilt Rochester Cathedral.
88	Odo, prior of Croyland, of England.	—	Monastic church of Croyland. Arnold, a lay brother of the abbey, was employed under Odo as mason.
89	Ernulf, bishop of Rochester, of England.	—	Completed Gundulf's works at Rochester.
90	Alexander, bishop of Lincoln, of England.	—	Rebuilt Lincoln Cathedral.
91	Ranulf, or Ralf Flambard, bishop of Durham, of England.	—	Part of Durham Cathedral ; Norham Castle.

## LIST OF ARCHITECTS.

AFTER CHRIST.			
No. in Gloss.	Name of Architect.	Century.	Principal Works.
92	Henry of Blois, bishop of Winchester, of England.	12th.	A most celebrated architect; built the conventual churches of St. Cross and Rumsey in Hampshire.
93	Raimond of Montfort, of France.	—	Cathedral of Lugo.
94	Dioti Salvi of Italy.	—	Baptistery of Pisa, near the Campo Santo. His works were in the Lombard style, and were overloaded with minute ornaments.
95	Buono of Venice.	—	The tower of St. Mark at Venice, which is 330 feet high, and 40 feet square, built in 1154; a design for enlarging the church of Santa Maria Maggiore at Florence, of which the master walls still exist; the Vicaria and the Castello del' Uovo at Naples; church of St. Andrew at Pistola; la Casa della Città; campanile at Arezzo.
96	Sugger of St. Denis, of France.	—	Rebuilt the church and abbey of St. Denis, near Paris. He was distinguished by his perfection in the Gothic style.
97	Roger, archbishop of York, of England.	—	None of his works at this cathedral are now remaining.
98	Pietro di Cozzo da Limena of Italy.	—	The celebrated great hall at Padua, which is 256 feet long, 86 wide, and 72 high, built in 1172, burnt in 1420, and restored by two Venetian architects, Rizzo and Piccino; it was dismantled by a whirlwind in 1756, and again restored by Ferracina.
99	Wilhelm, or Guglielmo, of Germany.	—	The hanging tower at Pisa, built in 1174. Bonnano and Tomaso, two sculptors of Pisa, were also engaged upon it.
100	William of Sens, of England.	—	Canterbury Cathedral.
101	Sisseverne, monk of St. Alban's, of England.	—	St. Alban's Abbey Church.
102	Goldclif, Hugo de, of England.	—	St. Alban's Abbey.
103	Eversolt, Gilbert de, of England.	—	St. Alban's Abbey.
104	Baldwin, archbishop of Canterbury, of England.	—	Church at Hackinton, near Canterbury; and another at Lambeth.
105	Isembert of Xaintes, of France.	13th.	Bridges of Xaintes and Rochelle. Recommended by King John to the citizens of London as a proper person to finish London Bridge, begun by Peter of Colechurch.
106	Peter of Colechurch, of England.	—	Began London Bridge.
107	Bertram, canon of Salisbury, of England.	—	Overseer of the works of Salisbury Cathedral, under John and Henry III. Lord Orford supposes he was the same person who is called Elyas the Engineer, in a record of the reign of King John, relating to the repair of the king's houses at Westminster in 1209.
108	Fitz-Odo, Edward, of England.	—	Master of the works at Westminster under Henry III.
109	Eustachius, bishop of Ely, of England.	—	Gallery of Ely Cathedral.

AFTER CHRIST.			
No. in Gloss.	Name of Architect.	Century.	Principal Works.
110	Robert of Lusarches, of France.	13th.	Cathedral of Amiens, which was continued by Thomas de Cormont, and finished by his son Renauld.
111	Etienne de Bonneveil of France.	—	Church of the Trinity at Upsal, in Sweden, built after the model of that of Notre Dame at Paris.
112	Poore, bishop of Salisbury, of England.	—	Began Salisbury Cathedral.
113	Melsonby, bishop of Salisbury, of England.	—	Part of the cathedral of Durham.
114	Hoo, W. de, prior of Rochester, of England.	—	Choir of Rochester Cathedral.
115	Jean d'Echelles of France.	—	The portico of the cathedral of Notre Dame at Paris.
116	Pierre de Montereau of France.	—	The holy chapel at Vincennes; the refectory, dormitory, chapter-house, and chapel of Notre Dame, in the convent of St. Germain des Prez, near Paris.
117	Eudo de Montreuil of France.	—	Church of the Hotel Dieu at Paris; churches of St. Catherine du Val des Ecoliers, of St. Croix de la Bretonnerie, of Blancs Manteaux, of the Mathurins, of the Cordeliers, and of the Carthusians, at Paris. His style was unpleasing and heavy.
118	San Gonsalvo of Portugal.	—	Stone bridge at Tui.
119	San Pietro of Portugal.	—	Stone bridge called Il Ponte de Carez.
120	Lapo, or Jacopo, of Germany.	—	Convent and church of St. Francisco at Assisi; Palazzo del Barjello; and the façade of the archbishop's palace at Florence.
121	Nicola da Pisa, of Pisa.	—	Convent and church of the Dominicans at Bologna; church of San Micheli; some palaces; and the octagonal campanile of the Augustins at Pisa; the great church del Santo at Padua; church of Santa Maria at Orvieto; church de'i Fratri Minori at Venice; abbey and church in the plains of Taliacozzo, in the kingdom of Naples, built as a memorial of the victory obtained there by Charles I. over Conrad; plans of the church of San Giovanni at Sienna; of the church and convent della Santissima Trinita at Florence, and of those of the Dominicans at Arezzo, which were built by Maglione, his scholar; the repairs and alterations to the duomo at Volterra; the church and convent of the Dominicans at Viterbo. He intermixed the Gothic with the Lombard style.
122	Fuccio of Italy.	—	Church of Santa Maria sul Arno at Florence; the gates against the river Volturno at Capua; he finished the Vicaria and Castello dell' Uovo at Naples, which were commenced by Buono; he was distinguished for his skill in fortification.
123	Fenante Maglione, disciple of Nicola of Pisa.	—	Cathedral and church of San Lorenzo at Naples; the Palazzo Vecchio at Naples, in conjunction with Giovanni Benin Casa; the church and convent of the Dominicans at Arezzo.

## AFTER CHRIST.

No. in Gloss.	Name of Architect.	Century.	Principal Works.
124	Masuccio of Naples.	13th.	Church of Santa Maria della Nuovo at Naples; churches of S. Dominico Maggiore and S. Giovanni Maggiore; the archiepiscopal palace and Palazzo Colombrano at Naples.
125	Arnolfo Fiorentino of Florence.	14th.	The abbey and church of Santa Croce at Florence; the walls of the city, with the towers; Palazzo della Signoria, now called Il Palazzo Vecchio; model and plan of the cathedral of S. Maria del Fiore, to which the cupola was added by Brunelleschi; the church and Piazza San Micheli; Piazza dei Priori. His works were greatly admired.
126	Pietro Perez of Spain.	—	The cathedral of Toledo.
127	Robert de Courcy of France.	—	Rebuilt the cathedral at Rheims.
128	Erwin von Steinbach of Germany.	—	Celebrated minster at Strasburg was superintended by him for twenty-eight years.
129	Giovanni da Pisa of Pisa.	—	Campo Santo, or public cemetery, at Pisa; the tribune of the Duomo in the same city; Castel Nuovo and the church of Santa Maria della Nuovo at Naples; façade of the cathedral at Sienna: many churches and palaces at Arezzo and other towns in Italy. He was the first architect in the modern style of fortification, and his churches and other buildings possess great merit. He was the son and scholar of Nicola da Pisa.
130	Andrea da Pisa of Pisa.	—	Plan of the fortress della Scarperia at Mugello, at the foot of the Apennines; plan and model of the church of San Giovanni at Pistoja; the ducal Palazzo Gualtieri at Florence. He was distinguished as a military architect.
131	Agostino da Sienna, or da Pisa, of Italy. Angelo, his brother, of Italy.	—	The north and west façades of the cathedral of Sienna, as also the two gates; the church and convent of St. Francis; Palazzo de' Nove Magistrati; grand fountain in the piazza opposite the Palazzo della Signoria; hall of the council chamber, and Palazzo Publico; the church della Santa Maria in Piazza Manetti were built by him in conjunction with Angelo da Pisa, who was his brother.
132	Boyden, William, of England.	—	Chief architect to the chapel of the Virgin at St. Alban's Abbey Church, erected during the abbacy of Hugo de Eversden.
133	Bek, A. de, bishop of Durham, of England.	—	Built and enlarged Barnard Castle, and other fortresses.
134	Henry Latomus, or the stonemason, abbot of Evesham, of England.	—	Chapter-house, dormitory, refectory, abbot's hall, and kitchen of the monastery at Evesham.
135	Helpstone, J., of England.	—	New-tower or water-tower, in the walls of Chester.
136	Eversden, Hugh de, abbot of St. Alban's, of England.	—	Lady chapel in St. Alban's Abbey Church.
137	Walter Weston of England.	—	St. Stephen's Chapel, Westminster.
138	Thomas of Canterbury, of England.	—	St. Stephen's Chapel, Westminster.

AFTER CHRIST.			
No. in Gloss.	Name of Architect.	Century.	Principal Works.
			the Aqua Vergine and the fountain of Trevi, at Rome, under Nicholas V.; the palace for the Duke Federigo Feltre at Urbino; and many other buildings in Italy.
163	Farleigh, or Ferley, W., abbot of Gloucester, of England.	15th.	Built the lady chapel of Gloucester, about 1490.
164	Beauchamp, bishop of Sarum, of England.	—	Appointed surveyor of the works at Windsor Castle by Edward IV.; supposed to have made designs for rebuilding St George's Chapel; built a chantry chapel in Salisbury Cathedral.
165	Wayneffete, bishop of Winchester, of England.	—	Founder of Magdalen College, Oxford; overseer of the building at Windsor. Leland was informed that the greatest part of the buildings of Eton College were raised under his direction, and at his expense.
166	Kendale, John, of England.	—	Supervisor of all the king's works.
166*	Druell, J., arch-deacon of Exeter, of England.	—	One of the architects employed on All Souls' College, Oxford.
167	Bramante Lazzari, or Bramante d'Urbino, of Castel Durante, near Urbino.	—	First designed and commenced the building of St. Peter's at Rome; a small model was executed after the same design for an insulated church without the walls of Todi; many works in the Vatican, particularly the library and the Belvedere court, with a magnificent design for alterations to be made in it, under Julius II.; the rotondo in the convent of San Pietro Montorio; the palaces of S. Giacomo Scosciacavalli ora de' Conti Giraud, del Duca de Sora, della Cancellaria, dell Nuovo dell' Imperiale; the churches of SS. Euloy de' Orfani, Lorenzo and Damaso; the cloisters of the monastery della Pace, &c. at Rome; the Strada Julia in that city; the ducal palace at Urbino; Palazzo Publico at Brescia; design for the church dell' Umiltà at Pistoja.
168	Ventura Vitoni of Pistoja.	—	Church dell' Umiltà at Pistoja, after the design of Bramante, whose pupil he was.
169	Alcock, J., bishop of Ely, of England.	16th.	Sepulchral chapel in Ely Cathedral; episcopal palace at Downham; supposed to have designed St. Mary's, or the University Church, Cambridge.
170	Moston, J., of Cambridge, of England.	—	Part of palace of Lambeth; another at Canterbury; "made a great building at Charing in Kent;" almost the whole house of Forde. He built at Alington Park.
171	Gabriello d'Agnolo of Naples.	—	Church of S. Giuseppe; church of Santa Maria Egiziaca; palace of Ferdinando Orsini, duke of Gravina, at Naples.
172	Gian Francesco Normando of Florence.	—	Church of S. Severino; Palazzo Filomarini; Palazzo Cantalupo at Naples; several buildings in Spain.
173	Pietro Lombardo of Venice.	—	Tomb of Dante, the poet, near the church of St. Francis at Ravenna; church of SS. Paolo, and Giovanni, and monastery adjoining the church of Santa Maria Mater Domini; clock-tower in the square of St. Mark; German warehouse on the Rialto; school della Misericordia; cloister of Santa Giustina at Padua.

AFTER CHRIST.			
No. in Gloss.	Name of Architect.	Century.	Principal Works.
174	Martino Lombardo of Venice.	16th.	School or confraternità of San Marco, and, perhaps, the church of S. Zaccaria at Venice.
175	John Cole of England.	—	Builder of Louth Spire, Lincolnshire.
176	Sir Reginald Bray of England.	—	Design of Henry VII.'s Chapel, Westminster, and of other works at St. George's Chapel, Windsor.
177	John Hylmer of England.	—	St. George's Chapel, Windsor.
178	Giuliano di San Gallo of Florence.	—	Cloister of the Carmelites di Santa Maddelena de' Pazzi at Florence; cloister for the Fratri Eremitani di S. Agostino; la Gran Fabbrica del Poggio Imperiale, fortress near the Porto a Prato, and other works, at Florence; a magnificent palace at Poggio Cajana for Lorenzo di Medici; repaired the cupola of the church della Madonna at Loreto; restored the roof and decorations of the ceiling of the church of Santa Maria Maggiore; restored the church dell' Anima; Palazzo Rovere, near San Pietro in Vincola at Rome; Palazzo Rovere at Savona; an unfinished palace at Milan; fortress and gate of San Marco, of the Doric order; many palaces at Pisa; fortifications at Ostia.
179	Simone Cronaca, or Pollajolo, of Florence.	—	Façade of the Palazzo Strozzi at Florence; church of S. Francis at S. Miniato, near Florence; convent of the Padri Serviti; sacristy of Santo Spirito, and the council chamber at Florence.
180	Aristotle Alberti of Bologna.	—	A bridge in Hungary; several churches in Russia.
181	Leonardo da Vinci, near Florence.	—	Aqueduct of the Adda at Milan; various machines, plans, and works on architecture.
182	Fra Giocondo of Verona.	—	Many bridges, especially that of Notre Dame at Paris; the public hall and Ponte della Pietra at Verona; fortifications at Treviso; cleansing of the Lagunes, and a design for the Ponte Rialto at Venice: after the death of Bramante, he was engaged with Rafaele and San Gallo in erecting St. Peter's at Rome.
183	Novella da San Lucano of Naples.	—	Palace of Prince Robert Sanseverino, duke of Salerno, at Naples; and the restoration of the church of San Domenico Maggiore, which was built by Lucano.
184	Percy, John, abbot of Leicester, of England.	—	Brick buildings at Leicester Abbey.
185	Rafaele d'Urbino of Urbino.	—	Continued the erection of St. Peter's at Rome, after the death of Bramante, his master in architecture; engaged on the buildings of the Farnese Palace; church of Santa Maria in Navicella, repaired and altered; stables of Agostino, near the Palazzo Farnese; Palazzo Caffarelli, now Stoppani; the gardens of the Vatican; the façade of the church of San Lorenzo, and of the Palazzo Uggoccioni, now Pandolfini, at Florence.
186	Bolton, W., prior of St. Bartholomew's of England.	—	Supposed to have designed Henry VII.'s Chapel, where he was master of the works.

AFTER CHRIST.			
No. in Gloss.	Name of Architect.	Century.	Principal Works.
139	Giacomo Lanfrani of Italy.	14th.	Church of St. Francis at Imola; church of St. Antonio at Venice.
140	Juan Rari of France.	—	Finished the building of the church of Notre Dame at Paris.
141	William of Wykeham, bishop of Winchester, of England.	—	New College, Oxford; part of Winchester Cathedral; plan of Windsor Castle.
142	Walsingham, prior of Ely, of England.	—	Lantern tower and tower of Ely Cathedral.
143	Rede, bishop of Chichester, of England.	—	An eminent mathematician; built first library at Merton College, Oxford; Amberly Castle, Sussex.
144	Andrea di Cione Orgagna, of Florence.	—	Additions to the ducal palace at Florence; his brother built the tower and gate of San Pietro Gattolini.
145	Gainsborough, or Gaynisburg, of England.	—	An architect employed at Lincoln Cathedral. On his monument, still existing in the cathedral, he is said to have died in June, M.C.CC—, the last portion of the date being obliterated.
146	Chichele, archbishop of Canterbury, of England.	15th.	Founded All Souls College; built a monument for himself in Canterbury Cathedral; made additions to Canterbury Cathedral, Lambeth Palace, Croydon Church, and Rochester Bridge.
147	Filippo Brunelleschi of Florence.	—	Cupola of the cathedral of Santa Maria del Fiore at Florence. A council of artists was held at Florence in 1420, to consider and advise on this scheme, at which even English artists are said to have assisted; after a diversity of opinions, Brunelleschi's project was approved of and adopted. His other principal works were, the Palazzo Pitti, which was begun and half finished by him, the remainder being the work of Luca Fancelli; a great part of the church of San Spirito; the church degl' Angeli, designed and begun, but not completed, from want of money; the monastery de' Camaldosi; the fortress of Milan, and several works about that city; a model for the fortress of Pesaro; the old and new citadel at Pisa; some other works there, as well as at Trento, and in other parts of Italy. He drained the country round Mantua, and set the first example of a purer style in the architecture of Italy.
148	Michelozzo Michelozzi of Florence.	—	Palazzo di Medici, now dei Marchesi Ricardi; Palazzo Caffajiulo; convent of the Dominicans; Noviziato della Santa Croce; chapel in the church dei Servi; Palazzo della Villa Careggi; Palazzo Tornabuoni, now dei Marchesi Corsi; and several other palaces, churches, and convents at Florence; monastery of the Black Benedictines at Venice, and the Palazzo della Villa Careggi at Mujello; some buildings at Trento; a beautiful fountain at Assisi, la Citadella Vecchia at Perugia; the alterations to the palace presented by Francisco Sforza to Cosmo di Medici, whom he followed in his exile, and other great works in various parts of Italy.

AFTER CHRIST.			
No. in Gloss.	Name of Architect.	Century.	Principal Works.
149	Giuliano of Majano, near Florence.	15th.	Palazzo del Poggio Reale at Naples; a Corinthian triumphal gate at the Castel Nuovo; many fountains in the same city; the Cortile S. Damaso, in the Vatican at Rome, whither he was invited by Paul II.; palace and church of San Marco at Rome; he also enlarged the church at Loreto.
150	Frowcester, Walter, abbot of Gloucester, of England.	—	Built the great cloisters of his monastery in 1400.
151	Keyes, Roger, of England.	—	Architect of All Souls' College, Oxford.
152	Horwood, W., a freemason, of England.	—	Collegiate chapel of Fotheringhay.
153	Close, or Cloos, bishop of Lichfield, of England.	—	Supposed to have designed King's College chapel, Cambridge; though, according to Hearne, his father was the architect.
154	Christobolo of Italy.	—	A mosque at Constantinople, with eight schools and eight hospitals, on the site of the church of the Apostles, by order of Mahomet II.
155	Baccio Pintelli of Florence.	—	Church and convent of Santa Maria del Popolo at Rome; the celebrated Capella Sistina in the Vatican; the hospital of S. Spirito in Sassia; Ponte Sisto; designs for the church of San Pietro in Montorio; the church of S. Sisto; the church of St. Agostino and the church of San Pietro in Vincolà at Rome; repaired the church and convent of St. Francis at Assisi; and built the palace for the Cardinal del Rovere at Borgo Vecchio; some attribute to him the palace built for the Duke Federigo Feltre at Urbino. He is said to have been the first to set the example of grandeur in the architecture of chapels.
156	Bartolomeo Bramantino of Italy.	—	Church of San Satiro at Milan, and other works in various parts of Italy.
157	Giovanni del Pozzo of Spain.	—	Dominican convent, and a great bridge over the Huexar, near Cuença.
158	Andrea Ciccione of Naples.	—	Convent and church of Monte Oliveto; palace of Bartolomeo da Capua; and several other convents and palaces in the city of Naples.
159	Ridolfo Fioravanti of Bologna.	—	Restored the hanging tower of the church of S. Biagio, at Cento, to its perpendicular position, and built many churches at Moscow.
160	Orcheyarde, W., of England.	—	Architect of Magdalen College, Oxford, under Bishop Waynefete.
161	Francesco di Giorgio of Sienna.	—	The ducal palace at Urbino.
162	Leon Battista Alberti of Florence.	—	Church of St. Francis at Rimini; church of St. Andrew at Mantua; the principal façade of Santa Maria Novella, at Florence, has been attributed by some to Alberti; but from the circumstance of its being Gothic, it may with much more probability be assigned to Bettini; the gate and Corinthian loggie are, however, from the designs of Alberti, as also the Doric façade of the Palazzo Rucellai, and the choir and tribune of the church della Nunziata, all at Florence. He also repaired

AFTER CHRIST.			
No. in Gloss.	Name of Architect.	Century.	Principal Works.
187	John of Padua of Italy.	16th	"Deviser of buildings" to Henry VIII. of England.
188	Gibbes, W., last prior of Bath, of England.	—	Continued the building of Bath Abbey church till the dissolution of monasteries.
189	Hector Asheley of England.	—	Surveyor of buildings, employed in the erection of Hunsdon House.
190	Andrea Contucci di Monte Sansovino of Italy.	—	The beautiful chapel del Sacramento in the church di Santo Spirito; palace della Canonica at Loreto; a cloister for the monks of St. Agostino, and a little chapel without the walls of Sanseverino; some buildings at Venice, and many in Portugal.
191	Bartolomeo Buono of Bergamo, of Italy.	—	Church of S. Rocco; some parts of the Campanile di San Marco, and the Procurazie Vecchie at Venice.
192	Guglielmo Bergamasco of Bergamo, of Italy.	—	Capella Emiliana of the Camaldulenses at Murano, an island of the Lagunes; Palazzo di Calmerlinghi, near the Ponte Rialto at Venice; palace at Portogruaro, at Friuli; gate di Santo Tommaso at Treviso; gate called Il Portello at Padua.
193	Maestro Filippo of Spain.	—	Restoration of the cathedral of Seville.
194	Giovanni di Olol-zago of Biscay, of Spain.	—	Cathedral of Huesca in Arragon: he blended the modern Greek style with the Gothic, in the manner called Arabo-tescheso.
195	Pietro di Gamiel of Spain.	—	Convent of S. Eugracia at Saragossa; college of Alcala, in the Græco-Gothic style of architecture.
196	Giovanni Alonzo of Spain.	—	Sanctuary of Guadalupe.
197	Fra Giovanni d'Escobedo of Spain.	—	Grand aqueduct of Segovia, by order of Queen Isabella.
198	Giovanni Campero of Spain.	—	Church and convent of S. Francis at Fordelaguna.
199	Antonio San Gallo of Mugello, near Florence.	—	Churches of the Madonna di Loreto near Trajan's column, of Santa Maria di Monserrato, of S. Giovanni dei Fiorentini; Palazzetto di Conte Palma; Palazzi di Santo Buono for himself, now that of the Marchesi Sacchetti; Farnese, begun by Paul III., when a cardinal; fortifications of Civita Vecchia, of Civita Castellana, of Parma, Ancona, and many other strong places in Italy; he altered the Mole of Adrian to its present form of the castle of S. Angelo; triumphal arch in the square of S. Mark at Venice; a temple to our Lady at Monte Pulciano; built the Capella Paolina del Vaticano, and assisted in the works of St. Peter's.
200	Baldassare Peruzzi of Volterra.	—	Plan and model of the cathedral or duomo at Carpi; two designs for the façade of San Petronio, and the gate of San Michele in Bosco at Bologna; fortifications at Sienna; the little palace built for Agostino Chigi, now called the Farnesina, in the Lungara; Palazzo Massimi, near the church of San Pantaleo; Villa di Papa Giulio III.; the cortile of the palace de' Duchi Attempis; casino at the Palazzo Chigi; tomb of Pope Hadrian IV. in

## AFTER CHRIST.

No. in Gloss.	Name of Architect.	Century.	Principal Works.
			the church dell' Anima; Palazzo Spinosa, now the hospital degli Eretici convertiti at Rome; assisted in the erection of St. Peter's, and was buried by the side of Raffaele, in the Pantheon. His style was good.
201	Marco di Pino of Sienna.	16th	Modernised the church della Trinità di Palazzo, and built the church and convent of Giesù Vecchio at Naples.
202	Andrea Briosco of Padua.	—	The Loggia and council house in the Piazza degli Signori at Padua, finished in 1526.
203	Ferdinando Manlio of Naples.	—	Church and hospital della Nunziata; the Strada di Porta Nolano, and di Monte Oliveto, with other streets and palaces at Naples; a bridge at Capua.
204	Giovanni Merliano of Nola of Italy.	—	Strada di Toledo at Naples; church of S. Giorgio de' Genovesi; church of S. Giacomo degli Spagnuoli; plan of the palace del Principe di San Severo, and the palace of the Duca della Torre; the Castel Capuano, altered to a court of law; a fountain at the extremity of the Mole, and some triumphal arches for the entrance of Charles V., on his return from Tunis, at Naples.
205	Giovanni Gil de Hontanon of Spain.	—	Plan of the cathedral of Salamanca.
206	Baccio d'Agnolo of Florence.	—	The beautiful bell tower or campanile of Santo Spirito; lantern above the cupola of Santa Maria del Fiore, great altar and choir of which was built by his son Giuliano; palace for Giovanni Bartolini in the Piazza della Santissima Trinità; Palazzo Salviato at Rome.
207	Giovanni Maria Falconetto of Verona.	—	Church della Madonna delle Grazie, for the Dominicans at Padua; palace in the Castel d'Usopo in the Friuli; palace for Luigi Cornaro, near the Santo; Doric gate to the Palazzo Capitano; a music hall, which was much admired by Serlio, who denominated it "La Rotondo di Padoua;" gates of SS. Giovanni and Savonarola.
208	Rodrigo Gil de Hontanon of Spain.	—	Superintended the erection of the cathedral of Salamanca; built the cathedral of Segovia.
209	Pietro de Uria of Spain.	—	Bridge of Almaraz, over the Tagus.
210	Alonzo de Cobarrubias of Spain.	—	Façade of the Alcazar at Toledo; convent and church of S. Michael at Valenza; repaired the church of Toledo, which was erected in 587, during the reign of King Riccaredo.
211	Diego Siloe of Toledo.	—	Cathedral and Alcazar at Granada; church and convent of S. Jerome in the same city.
212	Girolamo Genga of Urbino.	—	Palace of the Duke of Urbino, sul Monte dell' Imperiale; the court of the palace restored; church of San Giovanni Battista at Pesaro; façade of the cathedral and the bishop's palace at Mantua; convent de' Zoccolanti at Monte Baroccio. His son, Bartolomeo, was also an artist of considerable repute, and there are several of his works at Mondavio, Pesaro, and other parts of Italy.
213	Michele San Micheli.	—	Cathedral of Monte Fiascone; church of S. Domenico at Orvieto; numerous fortresses in

AFTER CHRIST.			
No. in Gloss.	Name of Architect.	Century.	Principal Works.
			the Venetian territory, in Corfu, Lombardy, and the ecclesiastical states, as at Legnani, Orzi Nuovo, and Castello; palaces di Canossa, dell' Gran Guardia on the Bra; Pellegrini de' Versi; the prefecturate and façade of the Palazzo Bevilacqua at Verona; chapel Guareschi in the church of S. Bernardino; design for the campanile of the Duomo; churches of Santa Maria in Organo de' Monaci, di Monte Oliveto, di San Giorgio, and della Madonna della Campagna, in the same city; gates Nuova, del Pallio, di S. Zenone, del Palazzo Pretorio, and del Palazzo Prefettizio, at Verona; fortifications of the same city, the first instance of the introduction of triangular bastions; the first bastion, that of della Madellina, was erected in 1527.
214	Philibert de Lorme of France.	16th.	Commenced the Tuilleries; built the châteaux of St. Maur, Anet, Meudon, and many others.
215	Galeazzo Alessi of Italy.	—	The Escorial in Spain; he was much employed at Genoa.
216	Sante Lombardo of Venice.	—	Palazzo Vendramini; staircase and façade of the school of S. Rocca; palaces Trevisani and Gradonigo, at Venice.
217	Giacomo Barozzi da Vignola of Rome.	—	The magnificent palace at Caprarola for Cardinal Farnese.
218	Giulio Pippi, or Giulio Romano, of Rome.	—	Villa Madama; Palazzo Lante at San Pietro; church della Madonna del Orto; Palazzo Ciccia porci alla Strada di Banchi; Palazzo Cenci sulla Piazza S. Eustachio, near the Palazzo Lante, and other buildings in Rome; Palazzo del T. at Mantua; palace at Marmiruolo, five miles from Mantua; modernising and enlarging the ducal palaces, the Duomo, and many other buildings in the same city; façade of S. Petronio at Bologna; and some works at Vicenza. His style was agreeable.
219	Michel Angelo di Buonaroti of Florence.	—	Library of the Medici, generally called the Laurentian Library, at Florence; model for the façade of the church of San Lorenzo; second sacristy of Lorenzo, commonly called the Cappella dei Depositi; church San Giovanni, which he did not finish; fortifications at Florence, and at Monte San Miniato; monument of Julius II. in the church of San Pietro in Vincola at Rome; plan of the Campidoglio; palace of the Conservatori; building in the centre, and the flight of steps in the Campidoglio, or Capitol, at Rome; continuation of the Palace Farnese, and several gates at Rome, particularly the Porta Nomentana or Pia; steeple of S. Michael at Ostia; the gate to the vineyard del Patriarca Grimani; tower of S. Lorenzo at Ardea; church of Santa Maria, in the Certosa, at Rome; many plans of palaces, churches, and chapels. He was employed on St. Peter's, after the death of San Gallo.

## LIST OF ARCHITECTS.

## AFTER CHRIST.

No. in Gloss.	Name of Architect.	Century.	Principal Works.
220	Mascul or Marshall, of Eng-land.	16th.	Clerk of the works to Cardinal Wolsey, at the building of Christchurch College, Oxford; and chief clerk of accounts for all the buildings of Henry VIII. within twenty miles of London.
221	Damiano Forment, of Valenza of Spain.	—	Façade of the church of S. Eugr��cia, at Saragossa.
222	Martino de Gainza of Spain.	—	The chapel royal at Seville.
223	Alonzo Berruguette, of Parades, de Naba, of Spain.	—	Plan of the former royal palace at Madrid; gate of S. Martino at Toledo; palace of Alcala in that city; he also assisted at the erection of the cathedral of Cuen��a.
224	Pietro di Valdevira of Spain.	—	The beautiful chapel of S. Salvador, at Ubeda; palace in the same place; hospital and chapel of S. Jago at Baeza.
225	Pietro Ezguerra of Ojeb��r, of Spain.	—	Cathedral of Plasencia; church of S. Matteo de Caceres; church of Malpartida.
226	Ferdinando Riuz of Cordova, of Spain.	—	Heightened the great steeple of the cathedral of Seville, called the Torre della Giralda.
227	Machuca of Spain.	—	Royal palace of Grenada.
228	Antonio Fiorentino of Florence.	—	Church of Santa Catarina a Formello at Naples; the cupola of this church is said to have been the first that was raised of any considerable magnitude in that city.
229	Jacopo Tatti, sur-named Sansovino, of Florence.	—	Church of S. Marcello begun, and that of S. Giovanni de Fiorentini built; Loggia, on the Via Flaminia, just out of the Porto del Popolo, for Marco Coscia; Palazzo Gaddi, now del Nicolini, at Rome; church of St. Francesco della Vigna, which was finished by Palladio; Palazzo Cornari, sul Canal Grande, at San Maurizio; mint and other public buildings at Venice; church of San Fantino; church of San Geminiano, &c. His style was of the Venetian school.
230	Theodore Havens of England.	—	Caius College, Cambridge, a good specimen of the architecture of the day.
231	Domenico Teocopoli of Greece.	—	College of the Donna Maria d'Arragona at Madrid; church and convent of the Dominican nuns; also of the Ayuntamiento at Toledo; church and convent of the Bernardine nuns at Silos.
232	Garzia d'Emere of Spain.	—	Parochial church of Valeria, near Cuen��a.

313	Fischer, Karl, of Germany.	—	Theatre, &c., Munich.
314	Dance, George, of England.	—	Newgate; St. Luke's Hospital.
315	Gandon, James, of Ireland.	—	Custom House, Exchange, Four Courts, &c., Dublin.
316	Soane, Sir John, of England.	—	Bank of England; Board of Trade; State Paper Office.
317	Percier, Charles, of France.	—	Architect of the Tuilleries; restorations, &c. at Louvre and Tuilleries; Chapelle Expiatoire. Author of Recueil de Decorations.

**ARCHITECTURE.** The art of building according to certain proportions and rules determined and regulated by nature and taste. As the art, in its various parts, is the subject of this work, we do not here consider further definition necessary. For origin and progress, see Book I. Chap. I. Sect. 2.; different species at early period, Book I. Chap. I. Sect. 3.

**ARCHITECTURE, ARABIAN or SARACENIC,** Book I. Chap. II. Sect. 10.

———— **BABYLONIAN,** Book I. Chap. II. Sect. 3.

———— **BRITISH, EARLY PERIOD,** Book I. Chap. III. Sect. 1.

———— **BYZANTINE and ROMANESQUE,** Book I. Chap. II. Sect. 14.

———— **CELTIC and DRUIDICAL.** See DRUIDICAL.

———— **CYCLOPEAN.** See PELASGIC.

———— **CHINESE,** Book I. Chap. II. Sect. 8.

#### I. GRECIAN ARCHITECTURE.

Aberdeen's, Earl of, Inquiry into the Principles of Beauty in Grecian Architecture. 8vo. London, 1822.

Aikin's, E., Essay on the Doric Order. Imperial folio. London, 1810.

Antiquities (the unedited) of Attica, comprising the Architectural Remains of Eleusis, Rhamnus, Sunium, and Thoricus. By the Society of Dilettanti, and edited by Wilkins, Gandy Deering, and Bedford. Imperial folio, 79 plates. London, 1817.

Antiquities of Ionia, by Chandler, Revett, and Pars. Imperial folio, plates, 2vols., London, 1817-23.

Chambers's Civil Architecture. Gwilt's Edition. Introductory Essay on Grecian Architecture. Imp. 8vo. London, 1825.

Chandler's, R., Travels in Asia Minor and Greece. 2 vols. 4to. London, 1817.

Choiseul, Gouffier. Voyage Pittoresque de la Grèce. 2 vols. folio. Paris, 1782—1809.

Cockerell's, C. R., Temple of Jupiter Olympius at Agrigentum. London, 1825.

Delagardette. Les Ruines de Pæstum, ou Posidonia. Royal folio. Paris, 1799.

Donaldson. Collection of the most approved Examples of Doorways from ancient Buildings in Greece and Italy. 2 vols. 4to. London, 1833.

Gartner, F. Monuments of Greece and Sicily. Folio. Munich, 1819.

Harris and Angell. Temple of Selinus. Large 4to. plates. London, 1826.

Hittorff. Architecture Antique de la Sicile. Paris, 1825-30-37.

Le Roy. Les Ruines, les plus beaux Monuments de la Grèce, considérées du Côté de l'Histoire, et du Côté de l'Architecture. Imp. folio, plates by Le Bas. Paris, 1758. Not a correct work.

Major, T. Ruines de Pæstum. 24 plates, large folio. 1768.

Quincy's, M. Quatremère de, Jupiter Olympien. Large folio, plates, some coloured. Paris, 1815.

———— Restitution des Deux Frontons du Temple de Minerve à Athènes. 4to. 3 plates, Paris, 1825.

Stanhope, J. S. Olympia; or Topography of the ancient State of the Plain of Olympia, and of the Ruins of the City of Elis. Imp. folio. London, 1824.

Stuart's, James, Antiquities of Athens. 4 vols. large folio. 1762, &c.

Stuart, James, F.R.S. F.S.A., and Nicholas Revett's Antiquities of Athens, a second edition, with a very considerable augmentation of notes of subjects further elucidated and brought to light by Travellers since the times of Stuart and Revett, edited by W. Kinnaird, architect, with an additional and entirely new volume (as supplement) of Architecture and Antiquities in Greece, Sicily, &c., the result of recent Travels and Investigations, by C. R. Cockerell, W. Kinnaird, T. L. Donaldson, W. Jenkins, and others, architects. 4 vols. royal folio, about 200 plates. 1825—1830.

The plates in the three first volumes of this edition are from the coppers of the French edition.

Visconti, Chevalier. Ouvrages de Sculpture du Parthenon. 8vo. Paris, 1818.

Wilkins, W. Antiquities of Magna Græcia. Imp. folio. Cambridge, 1807. An ill-drawn work.

———— Topography and Buildings of Athens. Royal 8vo., plates. 1816.

## II. ROMAN ARCHITECTURE.

- Adams, Robert. Ruins of the Palace of the Emperor Diocletian at Spalatro in Dalmatia. Folio, 61 plates. London, 1764.
- Allason, T. Picturesque Views of the Antiquities of Pola. Folio, 14 plates. London, 1817.
- Bartoli, P. S. Gli Antichi Sepolchri ovvero Mausolei Romani ed Etruschi. Folio, 110 plates. Roma, 1727.
- Colonna Trajana, a P. Bellori. 128 plates.
- Bellonii, J. P. Veteres Arcus Augustorum Triumphis insignes ex Reliquiis quæ Romæ adhuc supersunt per J. J. de Rubeis. Folio. Roma, 1690.
- Bianchi di Lugano, P. Osservazioni sull' Arena, e sul Podio dell' Anfiteatro Flavio. Folio. Roma, 1812.
- Bianconi, G. L. Descrizione dei Circhi. Folio, 20 plates. Roma, 1789.
- Cameron's Baths of the Romans explained and illustrated. Folio, 75 plates. London, 1772.
- Caristie. Plan et Coupe d'une partie du Forum Romain et des Monumens sur la Voie Sacrée. Atlas folio. Paris, 1821.
- Castell's Villas of the Ancients illustrated. Large folio. 1728.
- Ciampini, J. Rom. Vetera Monumenta. Romæ, 1747.
- Cipriani, G. B. Monumenti di Fabbriche Antiche. 4to. Roma, 1796.
- Desgodetz, A. Edifices de Rome, dessinées et mesurés très exactement. Folio, upwards of 300 plates. Paris, 1682.
- Gell, Sir W., and J. P. Gandy. Pompeiana; the Topography, Edifices, and Ornaments of Pompeii. 2 vols. imperial 8vo. London, 1824.
- Grangent, M. M., C. Durand, et S. Durant. Description des Monumens Antiques du Midi de la France. Folio, plates. Paris, 1819.
- Haudebourt, L. P. Le Laurentin; Maison de Campagne de Pliné le Jeune. Large 8vo. plates. Paris, 1838.
- Labacco, Ant. Appartenente all' Architettura nel qual si figurano alcune notabili Antiquità di Roma. Plates, folio. Roma.
- Maffei, Scipio. History of Ancient Amphitheatres. Translated by Gordon. 8vo. London, 1730.
- Mazois. Ruines de Pompeii. Paris, 1830.
- Nibby, Ant. Del Foro Romano, della Via Sacra, dell' Anfiteatro Flavio, e di Luoghi adjacenti. 8vo. Roma, 1819.
- Palladio, A. I Quattro Libri d'Architettura; whereof the last book is of ancient Roman Architecture. Several editions published at Venice. Figures on wood blocks.
- Il Tempio di Minerva in Assisi confrontato colle Tavole di Giov. Antolini. Folio. Milano, 1803.
- Les Termes des Romains dessinées. Par O. B. Scamozzi, d'après l' Exemple du Lord Burlington. Folio. Vicenza, 1785.
- Piranesi, Giov. Bapt. The works of (the son) subsequent to the death of John Baptist Piranesi. 29 vols. imperial folio, and double elephant folio. An abbreviated list of them is subjoined:—
- Vol. 1. Ruins of ancient Edifices of Rome, with the Explanation, Aqueducts, Baths, the Forum, &c. &c.
  - Vol. 2. Funeral Monuments, Cippi, Vases, &c. &c.
  - Vol. 3. Ancient Bas-reliefs, Stuccoes, Mosaics, Inscriptions, &c. &c.
  - Vol. 4. The Bridges of Rome, the Ruins of the Theatres, Porticoes, &c. &c.
  - Vol. 5. The Monuments of the Scipios.
  - Vol. 6. Ancient Temples, the Temples of Vesta, of Honour and Virtue, Statue of the Goddess Vesta, Altar to Bacchus, the Pantheon of-Rome, &c. &c.

 Rich's Ruins of Babylon. 8vo. London.  
 Tournefort's Voyage into the Levant. 2 vols. 4to. 1718.

Winckelman. *Rémarques sur l'Architecture des Anciens.* 8vo. Paris, 1783.

——— *Histoire de l'Art chez les Anciens.* 3 vols. 4to. Paris, 1790.

——— *Monumenti Antichi inediti.* 2 vols. folio, 184 plates. Napoli, 1820.

#### IV. GOTHIC ARCHITECTURE.

*Archæologia.* A work consisting of many vols. published by the Society of Antiquaries. It contains several essays on Gothic and English architecture, and subjects connected with it, as well as on ancient and modern architecture; but, as the society are not responsible for the lucubrations which appear in it, and the papers published are therefore merely to be considered as the opinions of their writers, there are extremely few on which a student could rely with safety; and we have therefore mentioned it as a work in which it is possible some points may be found valuable for his perusal; but this opinion is confined exclusively to the art in which we have presumed that we ourselves possess some small information; many of the historical and other articles in it being of great value.

Bardwell, W. *Temples, ancient and modern; or, Notes on Church Architecture.* Large 8vo. London, 1837.

Bentham, J. *History and Antiquities of the Church at Ely.* 4to. 1771.

——— *Essay on Gothic Architecture.* 8vo.

Blore. *Monumental Remains of noble and eminent Persons.* Imp. 8vo. London, 1826.

Britton. *Cathedrals, comprising Canterbury, York, Salisbury, Norwich, Oxford, Winchester, Litchfield, Hereford, Wells, Exeter, Worcester, Peterborough, Gloucester, and Bristol.* 4to. 1835.

As respects the graphic part of this work, it is one of great value to the student.

Britton, J. *Architectural Antiquities of Great Britain.* 4 vols. 4to. London, various dates.

——— *Chronological and Historical Illustrations of the ancient Ecclesiastical Architecture of Great Britain.* 4to. London, 1835.

——— *History and Antiquities of Bath Abbey.* Royal 8vo.

——— *History and Antiquities of Radclyffe Church.* 4to.

Britton and Brayley. *History of the ancient Palace and late Houses of Parliament at Westminster.* 8vo. London, 1836.

Boisserée, Sulpice. *Vues, Plans, Coupes, et Détails de la Cathédrale de Cologne, &c.* Very large folio. Stutgard, 1827.

Carter, J. *Ancient Architecture of England.* 2 vols. folio, 1837.

Cavaler, W. *Select Specimens of Gothic Architecture.* 4to. 80 plates. London, 1839.

Cotman, J. S. *Architectural Antiquities of Norfolk.* Folio, 60 plates.

——— *Architectural Antiquities of Normandy.* 2 vols. folio, 1820-1.

Cresy, Edw., and G. L. Taylor. *The Architecture of the Middle Ages at Pisa, from Drawings and Measurements in 1817, accompanied by descriptive Accounts of their History and Construction.* Imp. 4to. London, 1828-9.

Dallaway, Rev. James. *Observations on English Architecture.* Roy. 8vo. Lond. 1806.

——— *Notices of ancient Church Architecture in the Fifteenth Century.* 4to. 1824.

——— *Discourses on Architecture.* 8vo. London, 1833.

Ducarel. *Anglo-Norman Antiquities.* Plates, folio.

Dugdale, W. *History of St. Paul's Cathedral in London.* Folio, 1688.

Gage, J. *History and Antiquities of Hengrave in Suffolk.* Royal 4to. plates, 1822.

Gough. *Sepulchral Monuments in Great Britain.* Folio, 5 vols. London, 1796.

Grose, Captain. *Essay on Gothic Architecture.* 8vo.

Habershon, M. *Ancient half-timbered Houses of England.* 4to. London, 1836.

Halfpenny, J. *Gothic Ornaments in the Cathedral of York.* 4to. 105 plates, 1795.

——— *Fragmenta Vetusta; or, Remains of ancient Buildings in York.* Royal 4to. 34 plates, 1807.

Hall, Sir J. *Essay on the Origin, History, and Principles of Gothic Architecture.* 4to. 59 plates, 1813.

Hawkins, J. S. *Origin and Establishment of Gothic Architecture.* Plates, large 8vo. 1813.

King's *Monumenta Antiqua.* 4 vols. folio, plates. London, 1799.

Langlois, E. H. *Description Historique des Maisons de Rouen.* 8vo. with plates. Paris, 1821.

Lusson, A. L. *Specimen d'Architecture Gothique; ou Plans, Coupes, Elévations de la Chapelle du Château de Neuville.* Folio, 17 plates. Paris, 1839.

Mackenzie and Pugin. *Specimens of Gothic Architecture, consisting of Doors, Windows, Buttresses, Pinnacles, &c.* 4to. 62 plates.

Milan. *Nuovo Descrizione del Duomo di Milano, &c.* 8vo. plates. Milano, 1820.

Miller, G. *Description of the Cathedral Church of Ely, with some Account of the Conventual Buildings.* 1808.

- Milner, J. *Treatise on the Ecclesiastical Architecture of England*. Royal 8vo. plates. London, 1835.
- Moller, G. *Monumens de l'Architecture Allemande*. Folio, Darmstadt, 1836.
- Pugin, A. *Specimens of Gothic Architecture, selected from various ancient Edifices in England*. 4to. plates, 2 vols. London, 1823.
- *Examples of Gothic Architecture*. 3 vols. 4to. 224 plates. London, 1836.
- *Examples of Gothic Ornaments*. 4to. 90 plates, 1839.
- *Examples of Gothic Gables*. 4to. 30 plates, 1839.
- *Specimens of Anglo-Norman Architecture*. 4to. 80 plates, 1826.
- Shaw, H. *Series of Details of Gothic Architecture, selected from various Cathedrals, Churches, &c.* Folio. London, 1823.
- Smith, J. *Specimens of ancient Carpentry*. 4to. 36 plates.
- Vetusta Monumenta*: published by the Society of Antiquaries of London. 6 vols. large folio.
- Warton, Rev. T. *Essay on Gothic Architecture*. 8vo.
- Whittington, G. D. *Ecclesiastical Antiquities of France*. Large 8vo. London, 1811.
- Wild. *Cathedral Church of Lincoln*. 4to. London, 1838.
- Willement, T. *Regal Heraldry*. London, 1821.
- Winkles, B. *English Cathedrals*. 2 vols. London, 1837.
- Woolnoth. *Ancient Castles*. 2 vols. large 8vo. London, 1825.

#### V. MODERN FOREIGN ARCHITECTURE.

- Blondel, J. B. *Plan, Coupe, Elévation, et Détails, du nouveau Marché St. Germain*. Folio. Paris, 1816.
- Bonanni, P. P. *Templi Vaticani Historia*. Folio. Romæ, 1696.

## XI. ORNAMENTS.

Albertolli. *Corso Elementare di Ornamenti Archittonici.* Folio, 28 plates. Milan, 1805.

Architectural Ornaments. *A Collection of Capitals, Friezes, Roses, Entablatures, Mouldings, &c. drawn on Stone from the Antique.* 100 plates. London, 1824.

Beauvallet, P. N. *Fragmens d'Architecture, Sculpture, et Peinture dans le Style Antique.* Paris, 1804.

Choix des Monumens les plus remarquables des Anciens Egyptiens, des Persans, des Grecs, des Volsques, des Etrusques, et des Romains, consistans en Statues, Bas-Reliefs, et Vases. 2 tom. fol. 244 plates. Rome, 1788.

Colette, J. *Livre de divers Ornemens pour Plafonds, Cintres, Surbaissées, Galeries.* Folio, 10 plates. Paris.

Columbani, P. *Capitals, Friezes, and Cornices, &c.* 4to.

Fowler, W. *Collection of Mosaic, Roman and Norman tessellated Pavements and ancient stained Glass discovered in different parts of England.* Elephant folio size. Published at various times.

Gli Ornati delle Pareti ed i Pavimenti delle Stanze dell' Antica Pompeia. Atlas folio, 21 plates. Napoli, 1796.

Jalembier, C. A. *Principes d'Ornemens pour l'Architecture.* 40 plates. Paris.

Jombert, C. A. *Repertoire des Artistes; ou Recueil de Compositions d'Architecture et d'Ornemens, antiques et modernes, de tout Espèce, par divers Auteurs.* 2 vols. folio. Paris, 1765.

Le Noir, A. *Nouvelle Collection d'Arabesques propres à la Décoration des Appartemens dessinées à Rome par L. Poussin.* 4to. Paris.

Le Pautre. *Œuvres d'Architecture; contenant les Frises, Feuillages, Montans ou Pilastres, Grotesques, Moresques, Parmeaux, Placarts, Trumeaux, Lansbris, Amortissemens, Plafonds, et généralement tout ce qui concerne l'Ornement.* 3 tom. folio. Paris, 1751.

Moreau, C. *Fragmens, et Ornemens d'Architecture dessinés à Rome d'après L'Antique, formant un Supplément à l'Œuvre d'Architecture de Desgodetz.* Large folio, 36 plates. Paris.

Normand, C. *Nouveau Recueil en divers Genres d'Ornemens, et autres Objets propres à la Décoration.* Folio, 46 plates, Paris, 1803.

Percier, C. et P. F. L. Fontaine. *Recueil de Décorations Intérieures, comprenant tout ce qui a rapport à l'Ameublement.* Folio, 72 plates. Paris, 1812.

Pergolesi. *Ornaments.* Large folio, 30 plates. 1777.

Piroli, T. *Monumens Antiques du Musée Napoleon.* 4 tom. 4to., 40 plates. Paris, 1804.

Recueil d'Arabesques; contenant les Loges du Vatican, gravées d'après Raphael et grand Nombre d'autres Compositions du même Goût dans le Style Antique. Large folio, Paris, 1802.

Tatham, C. H. *Grecian and Roman Ornaments.* Folio, 101 plates. London, 1825.

Volpato. *Engravings of the Ornaments of the Vatican.*

Vulliamy, L. *Examples of Ornamental Sculpture in Architecture, containing 40 plates, imp. folio.* London, 1828.

**ARCHITRAVE.** (Gr. *Ἀρχαῖον*, to govern, and Lat. *Trabs*, a beam.) The lower of the three principal members of the entablature of an order, being, as its name imports, the chief beam employed in it, and resting immediately on the columns. It is sometimes called *Epistylum*, from *ἐπὶ*, upon, and *στυλος*, a column. The height of the architrave varied in the different orders, as also in different examples of the same order. See **GRECIAN ARCHITECTURE**, page 58. in the work; and, for its usual proportion, the orders from Sect. 5. to Sect. 7. Chap. I. Book III.

**ARCHITRAVE CORNICE.** An entablature consisting of an architrave and cornice only, without the interposition of a frieze. It is never used with columns or pilasters, unless through want of height. It is, however, allowable. See p. 748.

**ARCHITRAVE OF A DOOR OR WINDOW.** A collection of members and mouldings round either, used for the decoration of the aperture. The upper part, or lintel, is called the *traverse*, and the sides the *jambes*. See **ANTEPAGMENTA**.

**ARCHIVOULT.** (Lat. *Arcus volutus*.) The ornamental band of mouldings round the voussoirs, or arch-stones of an arch, which terminates horizontally upon the impost. It is decorated, as to the members, analogously with the architrave, which, in arcades, it may be said to represent. It differs in the different orders. See p. 721.

- ARCHIVOLTUM.** In mediæval architecture, an arched receptacle for filth. A cesspool or common sewer.
- ARCHWAY.** An aperture in a building covered with a vault. Usually an arched passage or gate wide enough for carriages to pass.
- ARCUS ECCLESIE.** In mediæval architecture, the arch dividing the nave of the church from the choir or chancel.
- ARCUS PRESBYTERII.** In mediæval architecture, the arch over the tribune marking the boundaries of its recess.
- ARCUS TORALIS.** In mediæval architecture, the lattice separating the choir from the nave in a basilica.
- AREA.** In Architecture, a small court or place, often sunk below the general surface of the ground, before windows in the basement story. It is also used to denote a small court even level with the ground.
- AREA.** In Geometry, the superficial content of any figure. See Section on **MENSURATION**, p. 372.
- ARENA.** The central space in a Roman amphitheatre, wherein the gladiators fought. See **AMPHITHEATRE**.
- ARGELIUS.** See **ARCHITECTS**, list of, 19.
- ARITHMETIC and ALGEBRA.** See Book II. Chap. I. Sect. 1.
- ARMOURY.** An apartment destined to the reception of instruments of war.
- ARNOLFO.** See **ARCHITECTS**, list of, 125.
- ARONADE.** Embattled; a junction of several lines forming indentations like the upward boundary of an embattled wall, except that the middle of every raised part is terminated by the convex arch of a circle, which arch does not extend to the length of that part.
- ARRIS** (probably abbreviated from the Ital. *a risega*, at the projection, or from the Sax. *arisan*, to arise). The intersection or line on which two surfaces of a body forming an exterior angle meet each other. It is a term much used by all workmen concerned in building, as the arris of a stone, of a piece of wood, or any other body. Though, in common language, the edge of a body implies the same as arris, yet, in building, the word *edge* is restrained to those two surfaces of a rectangular parallelepipedal body on which the length and thickness may be measured, as in boards, planks, doors, shutters, and other framed joinery.
- ARRIS FILLET.** A slight piece of timber of a triangular section, used in raising the slates against chimney shafts, or against a wall that cuts obliquely across the roof, and in forming gutters at the upper ends and sides of those kinds of skylights of which the planes coincide with those of the roof. When the arris fillet is used to raise the slates at the eaves of a building, it is then called the *eaves' board*, *eaves' lath*, or *eaves' catch*.
- ARRIS GUTTER.** A wooden gutter of this V form fixed to the eaves of a building.
- ARSENAL.** A public establishment for the deposition of arms and warlike stores.
- ARTIFICER.** (Lat. *Arts* and *Facio*.) A person who works with his hands in the manufacture of anything. He is a person of intellectual acquirements, independent of mere operation by hand, which place him above the *artisan*, whose knowledge is limited to the general rules of his trade.
- ASAROTUM.** In ancient architecture, a species of painted pavement used by the Romans before the invention of Mosaic work.
- ASH.** The *Fraxinus* of botanists. See **TIMBER**, Sect. on, p. 486.
- ASHELKY.** See **ARCHITECTS**, list of, 189.
- ASHLAR or ASHLER.** (Ital. *Asciare*, to chip.) Common or free-stones as brought from the quarry of different lengths and thicknesses.
- Also the facing given to square stones on the front of a building. When the work is smoothed or rubbed so as to take out the marks of the tools by which the stones were cut, it is called *plain ashlar*. *Tooled ashlar* is understood to be that whereof the surface is wrought in a regular manner, like parallel flutes, and placed perpendicularly in the building. But when the surfaces of the stones are cut with a broad tool without care or regularity, the work is said to be *random-tooled*. When wrought with a narrow tool, it is said to be *chiselled* or *boasted*, and when the surface is cut with a very narrow tool, the ashlar is said to be *pointed*. When the stones project from the joints, the ashlar is said to be *rusticated*, in which the faces may have a smooth or broken surface. In superior work, neither pointed, chiselled, nor random-tooled work are employed. In some parts of the country herring-bone ashlar and herring-bone random-tooled ashlar are used. See **MASONRY**, p. 518, *et seq.*
- ASHLERING.** In carpentry, the short upright quartering fixed in garrets about two feet six inches or three feet high from the floor, being between the rafters and the floor in order to make the room more convenient by cutting off the acute angle formed by the rafters.
- ASPECT.** (Lat. *Aspicio*.) The quarter of the heavens to which the front of a building faces. Thus a front to the north is said to have a north aspect.

- ASPHALTUM.** A bituminous substance found in various places and used as a building material. See Book II. Chap. II. Sect. 12.
- ASSEMBLAGE.** The joining or uniting several pieces together, or the union of them when so joined. Carpenters and joiners have many modes of accomplishing this, as by framing, mortise and tenon, dovetailing, &c. See PRACTICAL CARPENTRY AND JOINERY, p. 538, *et seq.*
- ASSEMBLAGE OF THE ORDERS.** The placing of columns upon one another in the several ranges. See ORDERS UPON ORDERS, Book III. Chap. I. Sect. 11.
- ASTRAGAL.** (Gr. *Αστράγαλος*, a die, or huckle bone.) A small moulding of a semicircular profile. Some have said that the French call it *talon*, and the Italians *tondino*; but this is a mistake, for the term is properly applied only to the ring separating the capital from the column. The astragal is occasionally cut into representations of beads and berries. A similar sort of moulding, though not developed in its profile as is the astragal, is used to separate the faces of the architrave.
- ATLANTIDES.** See CARYATIDES.
- ATRIUM.** In ancient Roman architecture, a court surrounded by porticoes in the interior part of Roman houses. According to Scaliger it is derived from the Greek *αἶθριος*, exposed to the air. By some it has been considered the same apartment as the *vestibule*, and Aulus Gellius intimates that in his time the two words were confounded. See, however, more on this head in the section on Roman Architecture in the body of the work, p. 100.
- ATTIC, or ATTIC ORDER.** (Gr. *Ἀττικός*, Athenian; facetiously, we supposed, derived, in the seventh edit. of Encyc. Brit. art. ARCHITECTURE, from *ἄτετον*, without a wall, which, if true, would transform all objects into attic things if detached from a wall.) A low order of architecture, commonly used over a principal order, never with columns, but usually with antæ or small pilasters. It is employed to decorate the façade of a story of small height, terminating the upper part of a building; and it doubtless derives its name from its resemblance in proportional height and concealed roof to some of the buildings of Greece. Pliny thus describes it after speaking of the other orders: "Præter has sunt quæ vocantur Atticæ columnæ quaternis angulis pari laterum intervallo." We, however, find no examples of square pillars in the remains of ancient art, though almost all the triumphal arches exhibit specimens of pilastral attics, having no capitals save the cornice breaking round them. In modern architecture the proportions of the attic order have never been subject to fixed rules, and their good effect is entirely dependent on the taste and feeling of the architect.
- ATTIC BASE.** The base of a column consisting of an upper and lower torus, a scotia and fillets between them. It is thus described by Vitruvius, "it must be so subdivided that the upper part be one third of the thickness of the column, and that the remainder be assigned for the height of the plinth. Excluding the plinth, divide the height into four parts, one whereof is to be given to the upper torus; then divide the remaining three parts into two equal parts, one will be the height of the lower torus, and the other the height of the scotia with its fillets.
- ATTIC STORY.** A term frequently applied to the upper story of a house when the ceiling is square with the sides to distinguish it from garrets. See Book III. Chap. I. Sect. 13.
- ATTRIBUTES.** In decorative architecture, are certain symbols given to figures, or disposed as ornaments on a building, to indicate a distinguishing character: as a lyre, bow, or arrow to Apollo; a club to Hercules; a trident to Neptune; a spear to Pallas, &c.
- AUGER.** A carpenter's and joiner's tool for boring large holes. It consists of a wooden handle terminated at the bottom with steel. The more modern augers are pointed and sharpened like a centre bit, the extremity of one of the edges being made to cut the wood clean at the circumference, and the other to cut and take away the core, the whole length of the radius.
- AVIARY.** (Lat. *Avīs*.) A house or apartment set apart for keeping and breeding birds.
- AVITUS, St.** See ARCHITECTS, list of, 58.
- AULA.** (Lat.) In ancient Roman architecture, a court or hall.
- AWNING.** (Fr. *Aulne*.) Any covering intended as a screen from the sun or protection from the rain.
- AXE.** (Sax. *eax*.) A tool with a long wooden handle and a cutting edge situate in a plane passing longitudinally through the handle. It is used for hewing timber by cutting it vertically, the edge being employed in forming horizontal surfaces. The axe differs from the joiner's hatchet by being much larger, and by its being used with only one hand. Axes of various sizes, depending upon the quality of the material, are used by stone-cutters and bricklayers.
- AXIS.** The spindle or centre of any rotative motion. In a sphere a line passing through the centre is the axis.

## B.

**BABYLONIAN ARCHITECTURE.** See Book I. Chap. II. Sect. 3.

**BACK.** The side opposite to the face or breast of any piece of architecture. In a recess upon a quadrangular plane, the face is that surface which has the two adjacent planes, called the sides, elbows, or gables. When a piece of timber is fixed in an horizontal or in an inclined position, the upper side is called the back, and the lower the breast. Thus the upper side of the handrail of a staircase is properly called the back. The same is to be understood with regard to the curved ribs of ceilings and the rafters of a roof, whose upper edges are always called the *backs*.

**BACK OF A CHIMNEY.** The recessed face of it towards the apartment, &c. See **CHIMNEY**.

**BACK OF A HAND-RAIL.** The upper side of it.

**BACK OF A HIP or other RAFTER.** The upper side or sides of it in the sloping plane of the side of the roof.

**BACK LINING OF A SASH FRAME.** That parallel to the pulley piece and next to the jamb on either side. See **JOINERY**, p. 563, *et seq.*

**BACK SHUTTERS.** Those folds of a shutter which do not appear on the face being folded within the boxing. See **JOINERY**, p. 570, *et seq.*

**BACK OF A STONE.** The side opposite to the face. It is generally rough.

**BACK OF A WALL.** The inner face of it.

**BACK OF A WINDOW.** The piece of wooden framing in the space between the lower part of the sash frame and the floor of the apartments, and bounded at its extremities right and left by the *elbows* of the window. The number of panels into which it is framed is dependent on what may be necessary for carrying out the design; it rarely, however, consists of more than one.

**BACKING OF A RAFTER or RIB.** The formation of the upper or outer surface of either in such a manner as to range with the edges of the rafters or ribs on either side of it. The formation of the inner edges of the ribs for a lath and plaster ceiling is sometimes called *backing*, but improperly, since contrary to the true meaning of the word.

**BACKING OF A WALL.** The filling in and building which forms the inner face of the work. In this sense it is opposed to facing, which is the outside of the wall. In stone walls the backing is unfortunately too often mere rubble, while the face is ashlar.

**BADIGEON.** A mixture of plaster and freestone sifted and ground together, used by statuary to repair defects in their work. The joiner applies this term to a mixture of sawdust and strong glue, with which he fills up the defects of the wood after it has been wrought. A mixture for the same purpose is made of whiting and glue, and sometimes with putty and chalk. When the first of these is used, it is allowed to remain until quite hard, after which it may be submitted to the operation of planing and smoothing. Without this precaution, it may shrink below the surface of the work.

**BAGNIO.** (It.) An Italian term for a bath, usually applied by the English to an establishment having conveniences for bathing, sweating, and otherwise cleansing the body. It is applied by the Turks to the prisons where their slaves are confined, in which it is customary to have baths.

**BAGUETTE.** (Fr.) A small moulding of the astragal species. It is occasionally cut with pearls, ribands, laurels, &c. According to M. Le Clerc, the baguette is called a *chaplet* when ornaments are cut on it.

**BAILEY.** See **CASTLE**.

**BAKEHOUSE.** An apartment provided with an oven and kneading troughs for baking.

**BALANEA.** A Greek term for a bath.

**BALCONY.** (It. Balcone.) A projection from the external wall of a house, borne by columns or consoles, and usually placed before windows or openings, and protected on the extremity of the projection by a railing of balusters or ironwork. In the French theatre, the *balcon* is a circular row of seats projecting beyond the tier of boxes immediately above the pit.

**BALDACHINO.** (It.) An open building, supported by columns, and covered with a canopy, generally placed over an altar. Sometimes the baldachino is suspended from the roof, as in the church of St. Sulpice at Paris. It succeeded to the ancient ciborium, which was a cupola supported on four columns, still to be seen in many of the churches of Rome. The merit of its invention seems to belong to Bernini. That erected by him in St. Peter's is 128 feet high, and being of bronze weighs near 90 tons. It was built by order of the Pope Barberini, from the robbery of the Pantheon, and occasioned the bitter observation, "*Quod non fecerunt Barbari fecerunt Barberini.*"

**BALDWIN.** See **ARCHITECTS**, list of, 104.

**BALEON or BOLEON MOULDINGS.** Mouldings which project beyond the surface of a piece of framing. See p. 569.

**BALKS or BAULKS.** (Dutch.) Sometimes called *dram* timber. They are pieces of whole

fir, being the trunks of small trees of that species, rough-squared for building purposes. In the metropolis the term is applied to short lengths, from eighteen to twenty-five feet, mostly under ten inches square, tapering considerably, and with the angles so left that the piece is not exactly square.

**BALLIUM.** In the architecture of the middle ages, the open space or court of a fortified castle. This has acquired in English the appellation *Bailey*; thus St. Peter's in the Bailey at Oxford, and the Old Bailey in London, are so named from their ancient connection with the sites of castles.

**BALLOON.** A round ball or globe placed on a column or pier, by way of crowning it. The same name is given to the balls on the tops of cathedrals, as at St. Peter's, which is 8 feet diameter, and at St. Paul's in London.

**BALNEUM.** (Lat.) A bath.

**BALTEUS.** (Lat. a girdle.) The wide step in theatres and amphitheatres, which afforded a passage round them without disturbance to the sitters. No one sat on it; it served merely as a landing-place. In the Greek and Roman theatres, every eighth step was a balteus. Vitruvius gives the rules for properly setting it out, in the third chapter of his fifth book.

The term balteus is also used by Vitruvius to denote the strap which seems to bind up the coussinet or cushion of the Ionic capital.

**BALUSTER.** A species of small column belonging to a balustrade. See Book III. Chap. I. Sect. 16. This term is also used to denote the lateral part of the volute of the Ionic capital. Vitruvius calls it *puleinata*, on account of its resemblance to a pillow.

**BALUSTRADE.** A parapet or protecting fence formed of balusters, sometimes employed for real use, and sometimes merely for ornament. For the method of designing balustrades, and other particulars relating to them, see Book III. Chap. I. Sect. 16.

**BAND.** (Fr. *Bande*.) A flat member or moulding, smaller than a fascia. The face of a band is in a vertical plane, as is also that of the fascia; the word, however, is applied to narrow members somewhat wider than fillets; and the word *fascia* to broader members. The cinctures sometimes used round the shafts of rusticated columns are called bands. In this case the column is called a *banded column*.

**BANDAGES.** A term applied to the rings or chains of iron inserted in the corners of a stone wall, or round the circumference of a tower, at the springing of a dome, &c., which act as a tie on the walls to keep them together.

**BANDELET, or BANDLET.** A small band encompassing a column like a ring.

**BANISTER.** A vulgar term for baluster, which see.

**BANKER.** A bench, on which masons prepare, cut, and square their work.

**BANQUET.** (Fr.) The footway of a bridge when raised above the carriage-way.

**BAPTISMAL FONT.** A vessel raised above the ground for containing the holy water used in the administration of baptism. Many of the fonts in Saxon churches are still in being. The plans and horizontal sections are commonly circles, octagons, or squares, and at a little later dates were elaborately decorated with mouldings and sculptures.

**BAPTISTERY.** (Gr. *Baptisterion*.) A building in the architecture of the middle ages, destined for administration of the rite of baptism. It has been contended by some that the baptistery was at first placed in the interior vestibules of the early churches, as are in many churches the baptismal fonts. This, however, was not the case. The baptistery was quite separate from the basilica, and even placed at some distance from it. Until the end of the sixth century, it was, beyond doubt, a distinct building; but after that period the font gradually found its way into the vestibule of the church, and the practice became general, except in a few churches, as at Florence, and in those of all the episcopal cities of Tuscany, Ravenna, of S. Giovanni Laterano at Rome, and some few other places. The last mentioned is perhaps the most ancient remaining. There was a baptistery at Constantinople, of such dimensions that, on one occasion, it held a very numerous council. That at Florence is nearly ninety feet in diameter, octagonal, and covered with a dome. It is enclosed by the celebrated bronze gates by Lorenzo Ghiberti, which Michel Angelo said were fit to be the gates of Paradise. The baptistery of Pisa, designed by Diotisalvi, was finished about 1160. The plan is octagonal, about 129 feet in diameter and 179 feet high. See p. 118.

**BAR.** In a court of justice, an enclosure, three or four feet high, in which the counsel have their places to plead causes. The same name is given to the enclosure, or rather bar before it, at which prisoners are placed to take their trials for criminal offences.

**BAR.** A piece of wood or iron used for fastening doors, window shutters, &c.

**BAR OF A SASH.** The light pieces of wood or metal which divide a window sash into compartments for the glass. The *angle bars* of a sash are those standing at the intersection of two vertical planes.

**BAR IRON** is that made of the metal of sows and pigs, as it comes from the furnace. The sows and pigs, as they are technically termed, pass through the forges and chaufery, where, having undergone five successive heats, they are formed into bars. See Sect. 5.

- Book II. Chap. II.** For the weight of a foot of bar iron of different thicknesses, see p. 590.
- BAR-POSTS.** Posts driven into the ground for forming the sides of a field gate. They are mortised, to admit of horizontal bars being put in or taken out at pleasure.
- BARBACAN.** A watch-tower for desecring an enemy: also the outer work or defence of a castle, or the fort at the entrance of a bridge. Apertures in the walls of a fortress, for firing through upon the enemy, are sometimes called by this name. The etymology of the word has been variously assigned to French, Italian, Spanish, Saxon, and Arabian origin. See **CASTLE**.
- BARGE BOARDS.** The inclined projecting boards placed at the gable of a building, and hiding the horizontal timbers of a roof. They are frequently carved with trefoils, quatrefoils, flowers, and other ornaments and foliage.
- BARGE COUPLES.** (Sax. *Býngan*, to bar.) Two beams mortised and tenoned together for the purpose of increasing the strength of a building.
- BARGE COURSE.** The part of the tiling which projects over the gable of a building, and which is made good below with mortar.
- BARN.** (Sax. *Beon*.) A covered farm-building for laying up grain, hay, straw, &c. The situation of a barn should be dry and elevated. It is usually placed on the north or north east side of a farm-yard. The barns, outhouses, and stables should not be far distant from each other. They are most frequently constructed with wooden framing of quarters, &c., and covered with weather boarding; sometimes, in superior farms, they are built of stone and brick. The roofs are usually thatched or tiled, as the materials for the purpose are at hand; but as the grain should of all things be kept dry, to prevent it from moulding, the gable ends should be constructed of brick, and apertures left in the walls for the free admission of air. The bays, as they are called, are formed by two pairs of folding doors, exactly opposite to each other, and, as well as for thrashing, afford the convenience of carrying in and out a cart or waggon load of corn in sheaves, or any sort of bulky produce. The doors in question must be of the same breadth as the threshing-floor, to afford light to the threshers, and air for winnowing the grain. It is a good practice to make an extensive penthouse over the great doors sufficiently large to cover a load of corn or hay, in case of the weather not permitting it to be immediately housed.
- BAROZZI DA VIGNOLA.** See **ARCHITECTS**, list of, 217.
- BARRACKS.** See **Book III. Chap. III. Sect. 19.**
- BARREL DRAIN.** One in the form of a hollow cylinder.
- BARYCÆ OR BARYCEPHALÆ.** (Gr. *βαρυς*, low or flat, and *κεφαλή*, head.) The Greek name for an *ærostyle* temple.
- BASE.** (Gr. *βασίς*.) In geometry, the lower part of a figure or body. The *base of a solid* is the surface on which it rests.
- BASE OF A COLUMN.** The part between the shaft and the pavement or pedestal, if there be any to the order. Each column has its particular base, for which see Sections 3 to 7. on the orders. For the Attic base see under that word.
- BASE OF A ROOM.** The lower projecting part. It consists of two parts, the lower whereof is a plain board adjoining the floor, called the plinth, and the upper of one or more mouldings, which, taken collectively, are called the base-mouldings. In better sort of work the plinth is tongued into a groove in the floor, by which means the diminution of breadth created by the shrinking never causes any aperture or chasm between its under edge and the floor, and the upper edge of the plinth is rebated upon the base. Bedrooms, lobbies, passages, and staircases are often finished without a dado and surbase, and indeed the fashion has extended the practice to rooms of the higher class, as drawing-rooms, &c.
- BASEMENT.** The lower story of a building, whether above or below the ground. See **Book III. Chap. I. Sect. 13.**
- BASIL.** Among carpenters and joiners the angle to which the edge of an iron tool is ground so as to bring it to a cutting edge. If the angle be very thin the tool will cut more freely, but the more obtuse it is the stronger and fitter it is for service.
- BASILICA.** (Gr. *βασιλεύς*, a king.) Properly the palace of a king; but it afterwards came to signify an apartment usually provided in the houses of persons of importance, where assemblies were held for dispensing justice. Thus in the magnificent villa of the Gordian family on the Via Prenestina there were three basilicæ, each more than one hundred feet long. A basilica was generally attached to every forum, for the summary adjustment of the disputes that arose. It was surrounded in most cases with shops and other conveniences for traders. The difference between the Grecian and Roman basilica is given by Vitruvius in the fifth chapter of his first book. The rise and progress of the modern basilica is given, p. 109, *et seq.* The term basilica is also applied by Palladio to those buildings in the cities of Italy similar in use to our town halls.
- BASIS.** See **BASE**.

**BASKET.** A term often applied to the vase of the Corinthian capital, with its foliage, &c.  
**BASSE COUR.** (Fr.) A court destined in a house of importance for the stables, coach-houses, and servants attached to that part of the establishment. In country houses it is often used to denote the yard appropriated to the cattle, fowls, &c.

**BASSO-RELIEVO.** See **RELIEVO**.

**BASTARD STUCCO.** See Sect. 9. Chap. III. Book II.

**BAT.** In bricklayer's work, a piece of a brick less than one half of its length.

**BATH.** (From the Saxon, *Bað*.) An apartment or series of apartments for bathing. Among the ancients the public baths were of amazing extent and magnificence, and contained a vast number of apartments. These extraordinary monuments of Roman magnificence seem to have had their origin in many respects from the gymnasia of the Greeks, both being instituted for the exercise and health of the public. The word *thermae* (hot baths) was by the Romans used to denominate the establishment, although it contained in the same building both hot and cold baths. In later times a house was incomplete unless provided with hot and cold baths; and, indeed, it was not till the time of Augustus that public baths assumed the grandeur which their remains indicate. Different authors reckon nearly eight hundred baths in Rome, whereof the most celebrated were those of Agrippa, Antoninus, Caracalla, Diocletian, Domitian, Nero, and Titus. It appears from good authority, that the baths of Diocletian could accommodate no less than eight hundred bathers. These stupendous edifices are indicative of the magnificence, no less than the luxury of the age in which they were erected. The pavements were mosaic, the ceilings vaulted and richly decorated, and the walls encrusted with the rarest marbles. From these edifices many of the most valuable examples of Greek sculpture have been restored to the world; and it was from their recesses that the restorers of the art drew their knowledge, and that Raffaele learnt to decorate the walls of the Vatican. See p. 96.

**BATERDEAU.** (Fr.) The same as coffer dam, which see.

**BATRACHUS.** See **ARCHITECTS**, list of, 33.

**BATTEN.** (Probably from the Fr. *Bâton*, from its small width.) A scantling or piece of stuff from two to six inches broad, and from five eighths of an inch to two inches thick. Battens are used in the boarding of floors and also upon walls, in order to receive the laths upon which the plaister is laid. See **BOARDED FLOOR**.

**BATTENING.** The fixing of battens to walls for the reception of the laths on which the plaster is to be laid. It also signifies the battens in the state of being fixed for that purpose. The battens employed are usually about two inches broad and three fourths of an inch thick; the thicknesses, however, may be varied according to the distances that the several fixed points are from each other. Their distance in the clear is from eleven inches to one foot. Before battens are fixed, equidistant bond timbers should be built in the wall, or the wall should be plugged at equal distances, and cut off flush with its surface. In and about London plugs are generally placed at the distance of twelve or fourteen inches from centre to centre in the length of the batten. Battens upon external walls, the ceiling and bridging joists of a naked floor, also the common joists for supporting the boarding of a floor, are fixed at the same distance, viz. from eleven to twelve inches in the clear. When battens are fixed against flues, iron holdfasts are of course employed instead of bond-timbers or plugs. When they are attached to a wall they are generally fixed in vertical lines, and when fixed to the surface of a stone or brick vault, whose intrados is generated by a plane revolving about an axis, they ought to be placed in planes tending to the axis; as in this position they have only to be fixed in straight lines, in case the intrados is straight towards the axis, which will be the case when it is a portion of a cone or cylinder; and when the intrados is curved towards the axis they will bend the easiest possible. Great care should be taken to regulate the fans of the battens, so as to be as nearly as possible equidistant from the intended surface of the plaster. Though battens are employed in floors, neither the act of laying them nor the floor afterwards formed of them is called battening; they are more commonly called *boarding*. Every piece of masonry or brickwork, if not thoroughly dry, should be battened for lath and plaster, particularly if executed in a wet season. When windows are boarded, and the walls of the room not sufficiently thick to contain the shutters, the surface of the plastering is brought out so as to give the architrave a proper projection, and quarterings are used for supporting the lath and plaster in lieu of battens. This is also practised when the breast of a chimney projects into the room, in order to cover the recesses and make the whole side flush, or all in the same surface with the breast.

**BATTER** (probably from the Fr. *Battre*). A term used by artificers to signify that a body does not stand upright, but inclines from a person standing before it; when, on the contrary, it leans towards a person, its inclination is described by saying it overhangs.

**BATTEMENTS.** Indentations on the top of a wall, parapet, or other building. They were first used in ancient fortifications, and subsequently applied to chambers and other build-

- ings as mere ornaments. Their outline is generally a conjunction of straight lines at right angles to each other, each indentation having two interior right angles, and each raised part two exterior right angles.
- BATTLE-EMBATTLED.** A term applied to the top of a wall which has a double row of battlements formed by a conjunction of straight lines at right angles to each other, both embrasures and rising parts being double, the lower part of every embrasure less than the upper, and therefore the lower part of each riser broader than the upper.
- BAULK ROOFING.** Roofing in which the framing is constructed of baulk timber.
- BAULKS.** See **BALKS.**
- BAY.** (Dutch, *Baye*.) The division of a barn or other building, generally from fifteen to twenty feet in length or breadth.
- BAY.** In plasterer's work, the space between the screeds prepared for regulating and working the floating rule. See **SCREEDS.**
- BAY OF JOISTS.** The joisting between two binding joists, or between two girders when binding joists are not used.
- BAY OF ROOFING.** The small rafters and their supporting purlins between two principal rafters.
- BAY WINDOW.** A window placed in the bay or bow of a window: called also an *oriel* window.
- BAYS.** See **DAYS.**
- BAZAR.** A species of mart or exchange for the sale of divers articles of merchandize. The word is Arabic, signifying the sale or exchange of goods or merchandize. Some of the Eastern bazars are open, like the market places of Europe, and serve for the same uses, more particularly for the sale of more bulky and less valuable commodities. Others are covered with lofty ceilings and even domes, which are pierced for the admission of light. It is in these that the jewellers, goldsmiths, and other dealers in rich wares have their shops. The bazar or *meidan* of Ispahan, one of the finest in Persia, is given in *fig. 32*.
- BEAD AND BUTT WORK.** Framing in which the pannels are flush, having beads *stuck* or run upon the two edges; the grain of the wood being in the direction of them. See p. 568.
- BEAD, BUTT, AND SQUARE WORK.** Framing with bead and butt on one side, and square on the other, is chiefly used in doors. This sort of framing is put together square, and the bead is *stuck* on the edges of the rising side of the pannel.
- BEAD AND FLUSH WORK.** A piece of framed work with beads run on each edge of the included pannel. See p. 568.
- BEAD, FLUSH, AND SQUARE WORK.** Framing with bead and flush on one side, and square on the other, used chiefly in doors.
- BEAD AND QUIRK.** A bead stuck on the edge of a piece of stuff, flush with its surface, with only one quirk or without being returned on the other surface. *Bead and double quirk* occurs when the bead appears on the face and edge of a piece of stuff in the same manner, thus forming a *double quirk*.
- BEADE.** (Sax. *Beabe*.) A moulding whose section is circular. It is frequently used on the edge of each fascia of an architrave, as also in the mouldings of doors, shutters, skirtings, imposts, and cornices. When the bead is flush with the surface it is called a *quirk-bead*, and when raised it is called a *cock-bead*.
- BEAK.** A little pendent fillet left on the edge of the larmier, forming a canal behind to prevent the water from running down the lower bed of the cornice. The beak is sometimes formed by a groove or channel recessed on the soffit of the larmier upwards.
- BEAM** (Sax. *Beam*, a tie.) A piece of timber, or sometimes of metal, for supporting a weight, or counteracting two opposite and equal forces, either drawing it or compressing it in the direction of its length. A beam employed as a lintel supports a weight; if employed as a tie beam, it is drawn or extended; if as collar beam, it is compressed. The word is usually employed with some other word used adjectively or in opposition, which word implies the use, situation, or form of the beam; as *tie beam*, *hammer beam*, *dragon beam*, *straining beam*, *camber beam*, *binding beam*, *girding beam*, *truss beam*, *summer beam*, &c. Some of these are however used simply, as collar for collar beam, lintel for lintel beam, &c. That which is now called the collar beam was by old writers called *wind beam*, and strut or *strutting beam*. A beam is lengthened either by building it in thicknesses, or by lapping or splicing the ends upon each other and bolting them through, which is called *scarfing*. See **CARPENTRY** generally, and p. 542.
- BEAM COMPASSES.** An instrument for describing large circles, and made either of wood or metal with sliding sockets, carrying steel or pencil points. It is used only when the circle to be described is beyond the reach of common compasses.
- BEAM FILLING.** The brickwork or masonry brought up from the level of the under to the upper sides of the beams. It is also used to denote the filling up of the space from the top of the wall plate between the rafters to the under side of the slating, board, or other covering.

- BEARER.** That which supports any body in its place, as a wall, a post, a strut, &c. In gutters they are the short pieces of timber which support the boarding.
- BEARING.** The distance or length which the ends of a piece of timber lie upon or are inserted into the walls or piers; thus joists are usually carried into the walls at least nine inches, or are said to have a nine-inch bearing. Lintels of an aperture should in like manner have a similar bearing, the object being to prevent any *sagging* of the piece acting on the inner horizontal quoins of the wall.
- BEARING OF A TIMBER.** The unsupported distance between its points of support without any intervening assistance. A piece of timber having any number of supports, one being placed at each extremity, will have as many bearings, wanting one, as there are supports. Thus a piece of timber extended lengthwise, as a joist over two rooms, will have three supports and two bearings, the bearers being the two outside walls and the partition in the midst between them.
- BEARING WALL OR PARTITION.** A wall or partition built from the solid for the purpose of supporting another wall or partition, either in the same or in a transverse direction. When the latter is built in the same direction as the supporting wall it is said to have a *solid bearing*; but when built in a transverse direction, or unsupported throughout, its whole length is said to have a *false bearing*, or as many false bearings as there are intervals below the wall or partition.
- BEATER.** An implement used by plasterers and bricklayers for beating, and thereby tempering or incorporating together the lime, sand, and other ingredients of a cement or plaster.
- BEAUCHAMP.** See ARCHITECTS, list of, 164.
- BEAUFET.** See BUFFET.
- BEAUTY.** In architectural composition, see Book III. Chap. I. Sect. 1.
- BED.** (Sax. *Beð*.) The horizontal surface on which the stones, bricks, or other matters in building lie. The under surface of a stone or brick is called its *under bed*, and the upper surface its *upper bed*. In general language the beds of a stone are the surfaces where the stones or bricks meet. It is almost needless to inculcate the necessity of every stone being worked quite straight, and not dishd or hollowed out, which masons are very apt to do for the purpose of making a fine joint. Stones thus worked are very liable to flush and break off at the angles, of which there are too many examples in important buildings to make it necessary that we should more particularly allude to them. See MASONRY, p. 518, *et seq.*
- BED CHAMBER.** The apartment destined to the reception of a bed. Its finishings of course depend on the rank of the party who is to occupy it.
- BED OF A SLATE.** The under side of a slate, or that part in contiguity with the boarding or rafters.
- BEDS OF A STONE.** In cylindrical vaulting are the two surfaces intersecting the intrados of the vault in lines parallel to the axis of the cylinder. In conic vaulting, where the axis is horizontal, they are those two surfaces which, if produced, would intersect the axis of the cone. In arching the beds are called *summerings* by the workmen.
- BEDDING OF TIMBERS.** The placing them properly in mortar on the walls.
- BEECH.** One of the forest trees, but not often used in building. See p. 484.
- BEEBLE.** (Sax. *Bytel*.) A large wooden hammer or mallet with one, two, or three handles for as many persons. With it piles, stakes, wedges, &c., are driven.
- BEK, DE.** See ARCHITECTS, list of, 133.
- BELECTION MOULDINGS.** See BALECTION MOULDINGS.
- BELFRY.** The upper part of the steeple of a church for the reception of the bells. It is the campanile of the Italians, though amongst them a building often altogether unconnected with the body of the church. It is sometimes used more especially in respect of the timber framing by which the bells are supported.
- BELL OF THE CORINTHIAN AND COMPOSITE CAPITALS.** The naked vase or *corbeille* round which the foliage and volutes are arranged. Its horizontal section is every where a circle. See *fig.* 93.
- BELL ROOF.** One whereof the vertical section, perpendicular to the wall or to its springing line, is a curve of contrary flexure, being concave at the bottom and convex at the top. It is often called an oggee roof from its form.
- BELT.** In masonry, a course of stones projecting from the naked, either moulded, plain, fluted, or enriched with pateras at regular intervals.
- BELVEDERE.** (It.) A raised turret or lantern raised for the enjoyment of a prospect; also a small edifice in gardens, not uncommon in France and Italy.
- BENCH.** A horizontal surface or table about two feet eight inches high, on which joiners prepare their work.
- BENCH HOOK.** A pin affixed to a bench for preventing the stuff in working from sliding out of its place.
- BERGAMASCO.** See ARCHITECTS, list of, 192.

**BERNINI.** See ARCHITECTS, list of, 251.

**BERRUGUETTE.** See ARCHITECTS, list of, 223.

**BERHAM.** See ARCHITECTS, list of, 107.

**BETON.** (Fr.) A species of concrete.

**BEVEL.** (Lat. *Bivium*.) An instrument used by artificers, one leg whereof is frequently curved according to the sweep of an arch or vault. It is moveable upon a pivot or centre, so as to render it capable of being set to any angle. The make and use of it are much the same as those of the common square and mitre, except that those are fixed, the first at an angle of ninety degrees and the second at forty-five; whereas the bevel being moveable, it may in some measure supply the office of both, and yet supply the deficiency of both, which is, indeed, its principal use, inasmuch as it serves to set off or transfer angles either greater or less than ninety or forty-five.

Any angle that is not square is called a *bevel angle*, whether it be more obtuse or more acute than a right angle; but if it be one half as much as a right angle, viz. forty-five degrees, the workman calls it a *miter*. They have also a term *half miter*, which is an angle one quarter of a quadrant or square, that is, an angle of twenty-two degrees and a half.

**BILLET MOULDING.** (Fr. *Billet*.) A Norman moulding used in string courses and the archivolts of openings. It consists of short, small, cylindrical pieces, two or three inches long, placed in hollow mouldings at intervals equal to about the length of the billet. See p. 174.

**BINDING JOISTS.** Those beams in a floor which, in a transverse direction, support the bridging joists above, and the ceiling joists below. (See CARPENTRY, p. 541.) When they are placed parallel to that side of a room on which the chimney stands, the extreme one on that side ought never to be placed close to the breast, but at a distance equal to the breadth of the slab, in order to allow for the throwing over the brick trimmer to support the hearth.

**BINDING RAFTERS.** The same as purlins, which see.

**BINNS FOR WINE.** The open subdivisions in a cellar for the reception of wine in bottles. The average diameter allowed for green bottles is 3.56 inches. Thus a binn 6 ft.  $2\frac{3}{4}$  in. long will take twenty-one bottles. If they are laid in double tiers the depth should be 32 inches.

**BIRCH.** A forest tree (*Betula*) sometimes used in building, see p. 487.

**BIRD'S MOUTH.** An interior angle cut on the end of a piece of timber, for the purpose of obtaining a firm rest upon the exterior angle of another piece.

**BISCOPUS.** See ARCHITECTS, list of, 67.

**BIT.** An instrument for boring holes in wood or any other substance, so constructed as to admit of being inserted or taken out of a spring. The handle is divided into five parts, all in the same plane; the middle and the two extreme parts being parallel. The two extreme parts are in the same straight line, one of them having a brass end with a socket for containing the bit, which, when fixed, falls into the same straight line with the other end of the stock; the further end has a knob attached, so as to remain stationary, while all the other parts of the apparatus may be turned round by means of the projecting part of the handle.

There are various kinds of bits: as *shell bits*, used for boring wood, and having an interior cylindric concavity for containing the core; *centre bits* used to form a large cylindric hole or excavation; *countersink bits*, for widening the upper part of a hole in wood or iron, to take in the head of a screw or pin, so that it may not appear above the surface of the wood; *primer bits*, for widening holes; and *taper shell bits*, used also for the last named purpose.

**BITUMEN.** A mineral pitch used in former ages instead of mortar. The walls of Babylon are said to have been cemented with it.

**BLADES.** (Sax. *Blæb*.) A name sometimes given to the principal rafters of a roof.

**BLADE OF A CHISEL.** The iron or steel part of it as distinguished from the wooden handle.

**BLADE OF A SAW.** The thin steel part on the edge of which the teeth are cut. The chief properties of a good saw are, that it should be stiff and yet bend equally into a regular curve, well tempered, equally thick on the cutting edge, and thinner towards the back edge.

**BLANK DOOR.** A door either shut to prevent a passage, or one placed in the back of a recess, where there is no entrance, having, nevertheless, the appearance of a real door.

**BLANK WINDOW.** One which has the appearance of a real window but is merely formed in the recess of the wall. When it is necessary to introduce blank windows for the sake of uniformity, it is much better to build the apertures like the other and real windows, provided no flues or funnels interfere; and instead of representing the sashes by painting, real sashes should be introduced with the panes of glass painted on the back.

- BLINDS.** Quadrangular frames of wood or metal, covered with an opaque substance, stretched between the framing, so as to cover either the whole or part of the sashes of a window. They are used for the purpose of diminishing the intense effects of the sun's rays, or of preventing passengers from seeing into the interior of an apartment.
- BLOCK (Teutonic) or WOOD.** A piece of wood cut into some prescribed form for a particular purpose.
- BLOCK OF STONE or MARBLE.** A piece rough from the quarry before it has received any form from the hand of the workman.
- BLOCKING or BLOCKING COURSE.** In masonry, a course of stones placed on the top of a cornice forming the crown of a wall.
- BLOCKINGS.** Small pieces of wood fitted in and glued to the interior angle of two boards, or other pieces, for the purpose of giving additional strength to the joint. In gluing up columns the staves are glued up successively and strengthened by blockings; as also the risers and treads of stairs and all other joints that demand more strength than their own joints afford. They are always concealed from the eye.
- BLOND, J. B.** See ARCHITECTS, list of, 274.
- BLONDEL, FR.** See ARCHITECTS, list of, 260.
- BLONDEL, JAC. FR.** See ARCHITECTS, list of, 293.
- BOARD. (Sax. BORD.)** A piece of timber of undefined length, more than four inches in breadth, and not more than two inches and a half in thickness. When boards are of a trapezoidal section, that is, thinner on one edge than the other, they are called *feather-edged boards*. Boards when wider than nine inches are called *planks*. The fir boards called *deal* (because they are *dealt* or *divided* out in thicknesses) are generally imported into England ready sawn, being thus prepared cheaper by saw mills abroad than they can be here. Fir boards of this sort, one inch and a quarter thick, are called *whole deal*, and those a full half inch thick, *slit deal*.
- BOARD LEAR or LEAR BOARD.** That upon which the lead work of a gutter is laid to prevent it sinking between the rafters.
- BOARDS, LISTED.** Such as are reduced in their width by taking off the sap from the sides.
- BOARDS FOR VALLEYS or VALLEY BOARDS.** Those fixed on the valley rafters, or pieces for the leaden gutters of the valley to rest on.
- BOARDED FLOORS.** Those covered with floor-boards. The laying of floors usually commences when the windows are in and the plaster dry. The boards should be planed on their best face and set up to season, till the natural sap is expelled. They are then to be planed smooth, shot, and squared on the edge. The opposite edges are brought to a breadth by drawing, with a flooring guage, a line on the face parallel to the other edge. After this they are guaged to a thickness, and rebated down on the back to the lines drawn by the guage. The next thing is to try whether the joists be level, and if not, either the boards must be cut on the under side to meet the inequality, or the joists must be *furred* up by pieces to bring the boards, when laid, to a level. The boards employed in flooring are either battens or deals of greater breadth. The quality of battens is divided into three sorts. The best is that free from knots, shakes, sap wood, or cross-grained stuff, well matched and selected with the greatest care. The second best is that in which only small but sound knots are permitted, but it is to be free from sapwood and shakes. The most inferior kind is that left from the selection of the other two. See p. 574.
- BOARDING JOISTS.** Those in naked floorings to which the boards are to be fixed.
- BOARDING FOR LEAD FLATS and GUTTERS.** That which immediately receives the lead, rarely less than one inch and an eighth, or one inch and a quarter thick. It is usually laid merely with rough joints.
- BOARDING LUFFER or LEVER BOARDING.** Inclined boarding, with intervals between the boards, nailed in an inclined direction on the sides of buildings or lanterns, so as to admit a free current of air, and at the same time to exclude the rain.
- BOARDING FOR PUGGING or DEAFENING, also called SOUND BOARDING.** Short boards disposed transversely between the joists of floors to hold some substance intended to prevent sound being transmitted from one story to another. These boards are supported by *fillets* fixed to the sides of the joists about three quarters of an inch thick and an inch wide. The substance, often plaster, placed between them to prevent the transmission of the sound, is called the *pugging*.
- BOARDING FOR SLATING.** That nailed to the rafters for the reception of the slates, usually three quarters to seven eighths of an inch in thickness; the sides commonly rough, the edges either rough, shot, plowed and tongued, or rebated and sometimes *sprung*, so as to prevent the rain from passing through the joints. The boarding for slating may be so arranged as to diminish the lateral pressure or thrust against the walls by disposing the boards diagonally on the rafters. On the lower edge of the boarding is fixed the

*eaves board*, as also against all walls either at right angles to or forming an acute angle with the ridge, or a right or obtuse angle with the wall plate. The eaves board is for raising the lower ends of the lower row of slates that form the eaves. Those placed against walls are for raising the slates to make the water run off from the wall. The boarding for slates should be of yellow deal without sap.

**BOARDING FOR LINING WALLS.** The boards used for this purpose are usually from five eighths to three quarters of an inch thick, and are plowed and tongued together.

**BOARDING FOR OUTSIDE WORK, or WEATHER-BOARDING.** Boards nailed with a lap on each other, to prevent the penetration of the rain and snow. The boards for this purpose are generally made thinner on one side than on the other, especially in good permanent work. The feather-edged board is, therefore, in such cases, used, the thick edge of the upper board being laid on the thin edge of that below, lapping about an inch or an inch and a half, and the nails being driven through the lap.

**BOASTER.** A tool used by masons to make the surface of the work nearly smooth. It is two inches wide in the cutting part.

**BOASTING IN MASONRY.** The act of paring the stone with a broad chisel and mallet, but not in uniform lines.

In CARVING, it is the rough cutting round the ornaments, to reduce them to their contours and profiles, before the incisions are made for forming the raffels or minuter parts. See **ASHLAR**.

**BODY of a NICHE.** That part of it whose superficies is vertical. If the lower part be cylindrical and the upper part spherical, the lower part is the *body* of the niche, and the upper part is termed the *head*.

**BODY RANGE of a GROIN.** The wider of two vaults which intersect and form a groin.

**BODY of a ROOM.** That which forms the main part of the apartment, independent of any recesses on the ends or sides.

**BOFFRAND.** See **ARCHITECTS**, list of, 280.

**BOLECTION MOULDING.** See **BALECTION MOULDING**.

**BOLSTER.** The baluster part of the Ionic capital on the return side. See **BALUSTER**.

**BOLT.** (Gr. *βολύς*, a dart.) In joinery, a metal fastening for a door, and moved by the hand, catching in a staple or notch which receives it. Bolts are of various sorts, whereof *plate spring* and *flush bolts* are for fastening doors and windows.

This name is also given to large cylindrical iron or other metal pins, having a round head at one end and a slit at the other. Through the slit a *pin* or *forelock* is passed, whereby the bar of a door, window shutter, or the like is made fast. These are usually called round or window bolts.

The bolt of a lock is the iron part that enters into a staple or jamb when the key is turned to fasten the door. Of these the two sorts are, one which shuts of itself when the door is shut to, called a *spring bolt*; the other, which is only acted upon by applying the key, is called the *dormant bolt*.

In carpentry, a bolt is usually a square or cylindrical piece of iron, with a knob at one end and a screw at the other, passing through holes for its reception in two or more pieces of timber, for the purpose of fastening them together, by means of a nut screwed on the end opposite to the knob. The bolt of carpentry should be proportioned to the size and stress of the timbers it connects.

**BOLTEL.** See **BOULTINE**.

**BOLTON.** See **ARCHITECTS**, list of, 186.

**BOND.** (Sax.) Generally the method of connecting two or more bodies. Used in the plural number, it signifies the timbers disposed in the walls of a house, such as *bond timbers*, *lintels*, and *wall plates*. The term *chain bond* is sometimes applied to the bond timbers placed in one or more tiers in the walls of each story of a building, and serving not only to tie the walls together during their settlement, but afterwards for nailing the finishings to.

**BOND.** In masonry or brickwork is that disposition of stones or bricks, which prevents the vertical joints falling over one another. See p. 519.

**BOND (HEART).** That bond which occurs when two stones being placed in a longitudinal position extending the exact thickness of the wall, another stone is put over the joints in the centre of the wall.

**BOND MASONRY.** See **BOUND MASONRY**.

**BOND STONES.** Those whose longest horizontal direction is placed in the thickness of the work. See p. 520.

**BONEING, or BONING.** (Etym. doubtful.) The act of judging of or making a plane surface or line by the eye. It is also performed by joiners with two straight edges, by which it is seen whether the work is out of *winding*, that is, whether the surface be plane or twisted.

**BONOMI.** See **ARCHITECTS**, list of, 308.

**BOOTH.** (British, Bwth.) A stall or standing in a fair or market. The term is also applied

to any temporary structure for shade and shelter, as also for wooden buildings for itinerant players and pedlars.

**BORDERS.** (Fr. Bord.) Pieces of wood put round the upper edges of any thing, either for use or ornament. Such are the three pieces of wood, to which the term in architecture is more usually applied, which are mitred together round the slab of a chimney-piece.

**BORING.** The art of perforating any solid. For wood the various sorts of bits are described under *BIT*.

**BORROMINI.** See *ARCHITECTS*, list of, 255.

**BOSS.** (Fr.) In sculpture, a projecting mass or promineny of material, to be afterwards cut or carved.

**BOSS.** Among bricklayers, a wooden vessel used by the labourers for the mortar used in tiling. It has an iron hook, by which it hangs on the laths or on the rounds of a ladder.

**BOSSAGE.** (Fr.) Projecting stones laid rough in building to be afterward cut into mouldings or carved into ornaments. The term is also used to signify rustic work, which seems to advance before the naked of a building, by reason of indentures or channels left at the joints. The cavities or indentures at the joints are sometimes bevelled or chamfered, and sometimes circular.

**BOUCHARDON.** See *ARCHITECTS*, list of, 284.

**BOULDER WALLS.** Such as are built of round flints or pebbles laid in strong mortar. This construction is used where there is a beach cast up by the sea, or where there is an abundance of flints in the neighbourhood.

**BOULTINE or BOLTEL.** A name sometimes given by workmen to a convex moulding, such as an ovolo.

**BOUND or BOND MASONRY.** That wherein the stones of each succeeding course are laid so that the joint which mounts and separates two stones always falls directly over the middle of the stone below.

**BOUTANT.** See *ARC-BOUTANT*.

**Bow.** (Sax. *Bugen*.) The part of any building which projects from a straight wall. It is sometimes circular and sometimes polygonal on the plan, or rather formed by two exterior obtuse angles. Bows on polygonal plans are called *canted bows*.

**Bow.** Among draughtsmen, denotes a beam of wood or brass, with three long screws that direct a lath of wood or steel to an arch. It is used in drawing flat arches of large radius.

**BOW COMPASSES** are instruments for describing small circles.

**BOW ROOM.** A room having a bow on one or more sides of it. See *BAY WINDOW*.

**BOW SAW.** One for cutting the thin edges of wood into curves.

**BOWLERS or BOLDERS.** See *PAVEMENT*.

**BOX.** (Sax.) Generally, a case for holding any thing.

**BOX FOR MITERING.** A trough for cutting miters. It has three sides, and is open at the ends, with cuts on the vertical sides at angles of forty-five degrees with them.

**BOX OF A RIB-SAW.** Two thin iron plates fixed to a handle, in one of which plates an opening is made for the reception of a wedge, by which it is fixed to the saw.

**BOX OF A THEATRE.** One of the subdivisions in the tiers round the circle.

**BOXED SHUTTERS.** See *BOXINGS OF A WINDOW*.

**BOXINGS OF A WINDOW.** The cases opposite each other on each side of a window, into which the shutters are folded or fall back. The shutters of principal rooms are usually in two divisions or halves, each subdivided into others, so that they may be received within the boxings. The subdivisions are seldom more in number than three, and are so contrived that the subdivision whose face is visible, which is called the front shutter, is of the exact breadth of the boxing, and also flush with it; the next, hidden in the boxing, is somewhat less in breadth than that last mentioned, and the third still less. Suppose, for instance, a window four feet wide, standing in a two-brick or eighteen-inch wall; we may thus find the number of leaves each of the halves must have, as follows:—To the thickness of the wall add that of the plastering, say 2 inches, and we have 20 inches. Now the sash frame = 6 inches in thickness, being added to the *reveal* or distance =  $4\frac{1}{2}$  inches of the sash frame from the face of the wall =  $10\frac{1}{2}$  inches, which, subtracted from 20, the thickness of the wall and plaster, leaves  $9\frac{1}{2}$  inches. This will give three leaves, or subdivisions, and as it is usual to make the *back flaps*, or those folded within the boxings, less than the front shutter, whose face is visible and flush with and of the exact breadth of the boxings, the arrangement may be as follows:—Front shutter  $9\frac{1}{2}$  inches, the next 8 inches, and the third  $6\frac{1}{2}$  inches; in all, 24 inches, the half of the opening of the window. It will be perceived that no allowance has been made for the shutters being rebated into each other, as is usually the case; and for this half an inch more must be allowed for the two rebates of the three leaves, and one eighth of an inch for the rebate at the meeting of the two principal divisions in the middle of the window, making, with the breadth of the three subdivisions,  $24 + \frac{1}{2}$ : the flaps, therefore, may be thus disposed:—Front leaf  $9\frac{1}{2}$

- inches, second leaf  $8\frac{1}{2}$  inches, and the third leaf  $6\frac{1}{2}$  inches; in all  $24\frac{1}{2}$  inches, being fully the width of each principal division. To find the depth to be given to the boxings, to the thickness of each of the leaves add one sixteenth of an inch, and if there be a back lining add also the thickness of that. The second and third flaps are almost always thinner than the front leaf; thus, say front leaf  $1\frac{1}{2}$  inch, second leaf  $1\frac{1}{4}$  inch, and third leaf  $1\frac{1}{4}$  inch; to which add  $\frac{3}{16}$  for the three leaves, and the amount will stand thus: —  $1\frac{1}{2} + 1\frac{1}{4} + 1\frac{1}{4} + \frac{3}{16} = 4\frac{3}{16}$  inches for the depth of the boxings. If the walls are only a brick and a half thick, or the window very wide, the architrave is made to project before the face of the plaster, for the purpose of obtaining width for the boxings, or the plaster is brought out from the internal face of the wall by means of battening.
- BOYDEN.** See ARCHITECTS, list of, 132.
- BRACE.** (Fr. Embrasser.) An inclined piece of timber used in trussed partitions and in framed roofs, in order to form a triangle, by which the assemblage of pieces composing the framing are stiffened. When a brace is used to support a rafter, it is called a *strut*. When braces are used in roofs and in partitions, they should be disposed in pairs, and introduced in opposite directions. See ANGLE BRACE.
- BRACKET.** (Lat. Brachium.) A supporting piece for a shelf. When the shelf is broad the brackets are small trusses, which consist of a vertical piece, an horizontal piece, and a strut; but when narrow the brackets are generally solid pieces of board, usually finished with an ogee figure on their outer side.
- BRACKETS FOR STAIRS** are sometimes used under the ends of wooden steps next to the well-hole, for the sake of ornament only, for they have only the appearance of supports.
- BRACKETING FOR CORNICES.** The wooden ribs nailed to the ceiling, joists, and battening for supporting the cornices of rooms when too large for security, by the mere dependence on the adhesive power of plaster to the ceiling. It consists of vertical ribs whose rough outline is that of the cornice, and to which the laths are nailed for sustaining the plaster in which the mouldings are run. The bracketing for coves is only an enlargement of the scale which occurs in ordinary cornices, the operation being that of obtaining a set of ribs to which the laths may be nailed for the reception of the plastering. The ribs in question are usually out of deals, whose thickness must necessarily vary with the weight of plaster they have to support. See p. 558, *et seq.*
- BRAD.** (Etym. uncertain.) A thin nail used in joinery without the spreading head which other nails have, the projection of the head being only on one side. There are various sorts of brads, such as *joiners' brads* for hard woods; others, called *batten brads*, for softer woods; and *bill*, or *quarter brads*, used for a hastily laid floor. When brads are used they are generally driven below the surface of the wood through the medium of a *punch*, and the hole is filled up with putty to prevent an appearance of the nailing.
- BRAMANTE.** See ARCHITECTS, list of, 167.
- BRAMANTINO.** See ARCHITECTS, list of, 156.
- BRANCHES.** The ribs of a Gothic vault, rising upwards from the tops of the pillars to the apex. They appear to support the ceiling or vault.
- BRANDRITH.** A fence or rail round the opening of a well.
- BRASS.** A metal much used in building. It is an alloy of copper and zinc, whose proportions vary according to the required colour. Four parts of copper and one of zinc form a good brass. The common process for making it is by heating copper plates in a mixture of native oxide of zinc, or calamine and charcoal.
- BRASSES.** Sepulchral plates, generally sunk into a flat grave-stone; sometimes with a mere inscription, but very frequently with effigies, armorial bearings, and other devices engraved upon it.
- BRATTISHING.** Interpreted, we know not how truly, as the carved open work over a shrine.
- BRAY.** See ARCHITECTS, list of, 176.
- BREADTH.** The greatest extension of a body at right angles to its length.
- BREAK.** The recess or projection of any part within or beyond the general face of the work. In either case it is to be considered a break.
- BREAK IN.** In carpentry, is the cutting or breaking a hole in brickwork with the ripping-chisel for the purpose of inserting timber, or to receive plugs, the end of a beam, or the like, &c.
- BREAKING JOINT.** In masonry or brickwork, is the placing a stone or brick over the course below, in such a manner that the joint above shall not fall vertically immediately above those below it.
- BREAST OF A CHIMNEY.** The projecting or facing portion of a chimney front towards a room which projects into it, or which, from other construction, may not have a break. It is, in fact, the wall carried up over the front of a fireplace, whether projecting or not. See CHIMNEY.
- BREAST OF A WINDOW.** The masonry or brickwork forming the back of the recess or parapet under the window sill.
- BREEZE.** Small ashes and cinders used instead of coal for the burning of bricks.

**BRESSUMMER or BREAST SUMMER.** That is, a summer or beam placed breastwise for the support of a superincumbent wall, performing in fact the office of a lintel. It is principally used over shop windows to carry the upper part of the front, and supported by iron or timber posts, though sometimes by stone. In the interior of a building the pieces into which the girders are framed are often called summers.

**BRETTFINGHAM.** See ARCHITECTS, list of, 294.

**BREWHOUSE.** An establishment for the manufactory of malt liquors. A brewhouse is generally provided as an appendage to dwelling-houses in the country, for brewing the beer used by the family.

**BRICK.** (Dutch, *Bricke*.) A sort of fictitious stone, composed of an argillaceous earth, tempered and formed in moulds, dried in the sun, and finally burnt to a proper degree of hardness in a clamp or kiln. (See Book II. Chap. II. Sect. 9.) The method pursued by the ancients in making unburnt bricks is described by Vitruvius, book ii. chap. iii. After mentioning the process, that author thus describes the different sorts in use: — "There are three sorts of bricks; the first is that which the Greeks call Didoron (*διδωρον*), being the sort we use, that is, one foot long and half a foot wide. The other two sorts are used in Grecian buildings; one is called Pentadoron, the other Tetradoron. By the word Doron, the Greeks mean a palm, because the word *δωρον* signifies a gift which can be borne in the palm of the hand. That sort, therefore, which is five palms each way is called Pentadoron; that of four palms Tetradoron. The former of these two sorts is used in public buildings; the latter in private. Each sort has half bricks made to suit it; so that when a wall is executed, the course on one of the faces of the wall shows sides of whole bricks, the other face of half bricks; and being worked to the line on each face, the bricks on each bed bind alternately over the course below. Besides the pleasant varied appearance which this method gives, it affords additional strength by the middle of a brick on a rising course falling over the vertical joints of the course thereunder." Towards the decline of the Republic, the Romans made great use of bricks as a building material. According to Pliny, those most in use were a foot and a half long, and a foot broad. This agrees nearly with the Roman bricks used in England, which are generally found to be about seventeen inches in length by eleven inches in breadth. Ancient bricks are generally very thin, being often no more than one inch and a half thick. From the article by Quatremère de Quincy in the *Encyc. Méthodique*, it appears from his researches among the antique buildings of Rome, he found bricks of the following sizes. The least were  $7\frac{1}{2}$  inches (French) square and  $1\frac{1}{4}$  inch thick; the medium one  $16\frac{1}{2}$  inches square, and from 18 to 20 lines in thickness. The larger ones were 22 inches square by 21 or 20 lines thick. The smaller ones were used to face walls of rubble work; and, for making better bond with the wall, they were cut diagonally into two triangles, the longer side being placed on the outside, and the point towards the interior of the work. To make the tie more effectual between the rubble and the facing, they placed at intervals of 4 feet in height, one or two courses of large square bricks. The larger bricks were also used for the arches of openings to discharge the superincumbent weight.

**BRICKLAYERS' WORK or BRICKLAYING.** See Book II. Chap. III. Sect. 2.

**BRICKWORK.** Any work performed with bricks as the solid material.

**BRIDGE.** (Sax. *Brūge*.) A structure for the purpose of connecting the opposite banks of a river, gorge, valley, &c., by means of certain materials, forming a road-way from one side to the other. It may be made of stone, brick, iron, timber, suspended chains or ropes, or the road-way may be obtained by means of boats moored in the stream. On the general principles for the situation and construction, the reader is referred to Book III. Chap. III. Sect. 2.; and for the principles and mode of constructing arches, to Book II. Chap. I. Sect. 9.

**BRIDGE BOARD,** otherwise called **NOTCH BOARD**, is a board on which the ends of the steps of wooden stairs are fastened.

**BRIDGE-OVER.** A term used when several parallel timbers occur, and another piece is fixed transversely over them, such piece is then said to *bridge-over* the parallel pieces. Thus in framed roofing, the common rafters bridge-over the purlins; so, in framed flooring, the upper joists, to which the flooring is fixed, bridge-over the beams or binding-joists, and for this reason they are called *bridging-joists*.

**BRIDGE STONE.** A stone laid from the pavement to the entrance door of a house, over a sunk area, and supported by an arch.

**BRIDGED GUTTERS** are those made with boards supported by bearers, and covered above with lead.

**BRIDGING FLOORS** are those in which bridging-joists are employed. See p. 541.

**BRIDGING JOISTS.** Those which are sustained by transverse beams below, called *binding joists*; also those joists which are nailed or fixed to the flooring-boards.

**BRIDGINGS or BRIDGING PIECES,** also called **STRUTTING or STRAINING PIECES**, are pieces placed between two opposite beams to prevent their nearer approach, as rafters, braces, struts, &c. When a strutting-piece also serves as a sill, it is called a *straining sill*.

- BRINGING-UP OF CARRYING-UP.** A term used by workmen to denote building up. Thus, *bringing-up* a wall four feet means building it up.
- BRIOSCO.** See ARCHITECTS, list of, 202.
- BROACHED WORK.** See DROVED and BROACHED.
- BROAD STONE.** The same as free-stone.
- BRONTEUM.** (Gr.) In ancient Greek Architecture, that part of the theatre under the floor in which brazen vessels with stones in them were placed to imitate the sound of thunder.
- BRONZE.** A compound metal applied to various useful and ornamental purposes. The composition consists of 6 to 12 parts of tin and 100 parts of copper. This alloy is heavier and more tenacious than copper; it is also much more fusible, and less liable to be altered by exposure to the air.
- BROSSE, JACQUES DE.** See ARCHITECTS, list of, 248.
- BRUNELLESCHI.** See ARCHITECTS, list of, 147.
- BUDGET.** A small pocket used by tilers for holding the nails in lathing for tiling.
- BUFFET.** (Fr.) A cabinet or cupboard for plate, glass, or china. Some years back it was the practice to make these small recesses very ornamental, in the form of niches, and left open in the front to display the contents. At present, when used, they are generally closed with a door.
- BUILDER.** A person who contracts for performing the whole of the different artificers' works in a building.
- BUILDING.** Used as a substantive is the mass of materials shaped into an edifice. As a participle, it is the constructing and raising an edifice suited to the purposes for which it is erected; the knowledge requisite for the design and construction of buildings being the subject of this work, in which it is treated under its various heads.
- BUILDING ACT.** An act passed 14 Geo. 3. cap. 78. for regulating buildings within the bills of mortality of London. See p. 819.
- BUILDING OF BEAMS.** The same as SCARFING. See p. 542.
- BULKER.** A term used in Lincolnshire to signify a beam or rafter.
- BULL'S EYE.** Any small circular aperture for the admission of light or air.
- BULL'S NOSE.** The external or other angle of a polygon, or of any two lines meeting at an obtuse angle.
- BULLEN NAILS.** Such as have round heads with short shanks turned and lacquered. They are principally used in the hangings of rooms.
- BULLOCK SHEDS.** Houses or sheds for feeding bullocks, in which the main points to be observed are good ventilation, facility in feeding and cleaning the animals, perfect drainage, and a good aspect. They ought not to be less than nineteen feet wide.
- BUNDLE PILLAR.** In Gothic architecture, a column consisting of a number of small pillars round its circumference.
- BUONARROTTI, M. A.** See ARCHITECTS, list of, 219.
- BUONO.** See ARCHITECTS, list of, 95.
- BUONO, BARTOLOMEO.** See ARCHITECTS, list of, 191.
- BUONTALENTI.** See ARCHITECTS, list of, 241.\*
- BURLINGTON, EARL OF.** See ARCHITECTS, list of, 293.
- BURROUGHS.** See ARCHITECTS, list of, 287.
- BUSCHETTO.** See ARCHITECTS, list of, 18.
- BUSTAMENTE.** See ARCHITECTS, list of, 233.
- BUT-HINGES.** Those employed in the hanging of doors, shutters, casements, &c. They are placed on the edges with the knuckle projecting on the side in which the *closure* is to open, and the other edges stopping against a small piece of wood left in the thickness of the closure so as to keep the arris entire. Workmen generally sink the thickness of the hinges flush with the surface of the edge of the closure, and the *tail part* one half into the jamb. Of but-hinges there are several kinds; such as *stop but-hinges*, which permit the closure to open only to a right angle, or perhaps a little more, without breaking the hinges; *rising but-hinges*, which are those that turn upon a screw; these are most employed in doors, and cause the door to rise as it opens, so as to clear the carpet in the apartment; *slip-off but-hinges*, which are those employed where a door or window blind is required to be taken off occasionally.
- BUTMENT.** The same as ABUTMENT, which see.
- BUTMENT CHEEKS.** The two solid sides of a mortise. The thickness of each cheek is usually equal to the thickness of the mortise, but it happens that circumstances arise to vary this thickness.
- BUTT-END OF A PIECE OF TIMBER.** That which was nearest the root of a tree.
- BUTTERY.** A store-room for provisions, which, if possible, should be on the north side of a building.
- BUTTING JOINT.** That formed by the surfaces of two pieces of wood, whereof one is perpendicular to the fibres, and the other in their direction, or making an oblique angle with them, as for example, the joints made by the struts and braces with the truss posts.

**BUTTON.** A small piece of wood or metal, made to turn about a centre for fastening a door, draw, or any other kind of closure. The centre is generally a nail, which should be smooth, rounded, and the head filed even.

**BUTTESS.** (Fr. *Aboutir*, to lie out.) A mass of brickwork or masonry to support the side of a wall of great height, or pressed on the opposite side by a bank of earth or body of water. Buttresses are employed against the piers of Gothic buildings to resist the thrust of the vaulting. See *ARC BOUTANT*, or flying buttress. The buttress called the pillared buttress is formed by vertical planes attached to the walls themselves. These sometimes form the upright terminations of flying buttresses.

## C.

**CABIN.** (Brit. *Chabin*.) A term applied to the huts and cottages of poor people and to those of persons in a savage state of life.

**CABINET.** (Fr.) A retired room in an edifice set apart for writing, study, or the preservation of any thing curious or valuable. The term is also applied to an apartment at the end of a gallery in which pictures are hung, or small pieces of sculpture, medals, bronzes, and other curiosities are arranged.

**CABLE.** A moulding of a convex circular section, rising from the back or concave surface of a flute, so that its most prominent part may be in the same continued circular surface as the fillet on each side of the flute. Thus the surface of a flute is that of a concave cylinder, and that of the cable is the surface of a convex cylinder, with the axes of the cylinders parallel to each other. The cable seems to represent a rope or staff laid in the flute, at the lower part of which it is placed about one third of the way up.

**CABLED COLUMN.** One in which cables, as described in the last article, are used.

**CABLED FLUTES.** Such as are filled with cables.

**CABLING.** The filling of the flutes with cables, or the cables themselves so disposed. Cabling of flutes was not frequently used in the works of antiquity. The flutes of the columns of the arch of Constantine are filled with cables to about one third of the height of the shaft. Most of the columns in the ruins of Baalbec, Palmyra, and the palace of Diocletian at Spalatro, have neither flutes nor cables. In modern times an occasional abuse has been practised of cabling without fluting, as in the church della Sapienza at Rome.

**CAER.** A term in British antiquity, which, like the Saxon term *Chester*, denotes a castle, and is generally prefixed to the names of places fortified by the Romans.

**CAGE,** in carpentry, is an outer work of timber inclosing another within it. Thus the cage of a stair is the wooden inclosure that encircles it.

**CAISSON.** (Fr.) A large and strong chest of timber, water-tight, used in large and rapid rivers for building the pier of a bridge. The bottom consists of a grating of timber, contrived in such a manner that the sides, when necessary, may be detached from it. The ground under the intended pier is first levelled, and the caisson being launched and floated into its proper position, it is sunk, and the pier built therein as high as the level of the water, or nearly so. The sides are then detached, and the pier, built as described, sinks down on the foundation prepared for it. The tonnage of each of the caissons used at Westminster Bridge was equal to that of a forty-gun ship.

**CAISSONS IN VAULTING.** The sunken pannels on ceilings, vaults, and cupolas. See *Book III. Chap. II. Sect. 3.*

**CALCAREOUS CEMENTS.** See *CEMENT* in the body of the work, p. 505, *et seq.*

**CALCAREOUS EARTH.** A species of earth which becomes friable by burning, and is afterwards reduced to an impalpable powder by mixing it with water. It also effervesces with acids. It is frequently met with in a friable or compact state in the form of chalk.

**CALDARIUM.** (Lat.) In ancient architecture a close vaulted room, in which persons were brought into a state of profuse perspiration. It was one of the apartments attached to ancient baths, and was also denominated *Vaporarium*, *Sudatorium*, and *Laconicum*.

**CALFEN.** A place for nourishing calves. It is generally a small apartment within the cowhouse; but the practice is not to be recommended, as it keeps the cow in a restless and agitated state, and prevents her from feeding well, and giving that quantity of milk she would otherwise furnish.

**CALIBER.** (Spanish.) The greatest extent or diameter of a round body.

**CALIBRE COMPASSES.** Those made with bent legs for taking the diameter of a convex or concave body in any part. See *MOULD*.

**CALIDUCTS.** (Lat.) Pipes or channels disposed along the walls of houses and apartments. They were used by the ancients to convey heat to the remote parts of the house from one common furnace.

**CALIPER.** See *CALIBER*.

**CALLIAS.** See *ARCHITECTS*, list of, 18.

- CALLICRATES.** See ARCHITECTS, list of, 13.
- CALLIMACHUS.** See ARCHITECTS, list of, 24.
- CALOTTE.** (Fr.) A concavity in the form of a cup or niche, lathed and plastered, serving to diminish the height of a chapel, alcove, or cabinet, which otherwise would appear too high for the breadth.
- CAMARORIS.** (Gr.) An elevation terminated with an arched or vaulted head.
- CAMBER.** (Gr.) An arch on the top of an aperture or on the top of a beam. Hence camber windows.
- CAMBER BEAMS.** Those which form a curved line on each side from the middle of their length. All beams should, to some degree, if possible, be cambered; but the cambered beam is used in flats and church platforms, wherein, after being covered with boards, these are covered with lead, for the purpose of discharging the rain-water.
- CAMERATED.** (Gr.) The same as arched.
- CAMES.** Small slender rods of cast lead in glazing, twelve or fourteen inches long, of which, by drawing them separately through a species of vice, the glaziers make their turned lead for receiving the glass of casements.
- CAMP CEILING.** A ceiling whose form is convex inwardly.
- CAMPANILE.** (It. a bell tower.) A tower for the reception of bells, usually, in Italy, separated from the church. Many of the campaniles of Italy are lofty and magnificent structures. That at Cremona is much celebrated, being 395 feet high. It consists of a square tower, rising 262 feet, surmounted by two octagonal open stories, ornamented with columns; a conical shaft and cross terminate the elevation. The campanile of Florence, from the designs of Giotto, though in bad taste, has claims on our admiration for its richness and the superiority of the workmanship. It is 267 feet high, and 45 feet square. The most remarkable of the campaniles in the country mentioned is that at Pisa, commonly called the "Leaning Tower." It is cylindrical in general form, and surrounded by eight stories of columns, placed over one another, each having its entablature. Each column carries the springing of two arches, and there is an open gallery between the columns and the circular wall of the tower. The height of the last story of columns, in which are the bells, is set back from the general line of the elevation. The height is about 150 feet to the platform, whence a plumb line lowered falls on the leaning side nearly 13 feet beyond the base of the building.
- CAMPBELL.** See ARCHITECTS, list of, 271.
- CAMPERO.** See ARCHITECTS, list of, 198.
- CAMP-SHEETING OR CAMPSHOT.** The sill or cap of a wharf wall.
- CANAL.** (It. Canale.) A duct for the conveyance of a fluid; thus the canal of an aqueduct is the part through which the water flows. In ancient aqueducts it was lined with a coat of mastic.
- CANAL.** A term sometimes used for the flutings of a column or pilaster. The *canal of the volute* is the spiral channel, or sinking on its face, commencing at the eye, and following in the revolutions of the volute. The *canal of the larmier* is the channel or groove sunk on its soffit to throw off the rain, and prevent it from running down the bed mould of the cornice.
- CANCELLI.** (Lat.) Latticed windows, or those made with cross bars of wood or iron. The balusters or rails which close in the bar of a court of justice, and those round the altar of a church, are also so called; hence the word *chancel*.
- CANDELABRUM.** (Lat. Candela.) A stand or support on which the ancients placed a lamp. Candelabra varied in form, and were highly decorated with the stems and leaves of plants, parts of animals, flowers, and the like. The etymology of the word would seem to assimilate the candelabrum to our candlestick; it is, however, certain that the word *candela* was but a lamp, whereof the candelabrum was the support. In the works of Piranesi some of the finest specimens are to be found. The most curious, however, as respects form, use, and workmanship, are those excavated at Herculaneum and Pompeii. They are all of bronze, slender in their proportions, and perfectly portable, as they rarely in height exceed five feet. On none of the candelabra hitherto found is there any appearance of a socket or pipe at top, from which an inference as to the use of candles could be made.
- CANEPHORÆ.** (Gr. *Κανηφορος*, bearing a basket.) Figures of young persons, of either sex, bearing on their heads baskets containing materials for sacrifice. They are frequently confounded with caryatides, from their resemblance in point of attitude and the modern abuse of their application.
- CANOPY.** (Gr. *Κανωπεϊον*.) An ornamented covering over a seat of state; and in its extended signification any covering which affords protection from above. It is also the label or projecting roof that surrounds the arches and heads of gothic niches.
- CANT.** An external angle or quoin of a building. Among carpenters it is used as a verb, to signify the turning of a piece of timber which has been brought in the wrong way for their work.

- CANT MOULDING.** One with one or more bevelled, instead of curved, surfaces. The cant moulding was used at an early period of the art.
- CANTALEVER or CANTILEVER.** (Probably from *Canterii labrum*, the *lip of the rafter*.) Blocks inserted into the wall of a building for supporting a balcony, the upper members of a cornice, or the eaves of a house, and the like. They answer the same purpose as modillions, mutules, blocks, brackets, &c., although not so regularly applied. They are, in modern use, not unfrequently made of timber or cast iron, and project considerably, as in the church of St. Paul, Covent Garden, which projects one quarter of the height of the column.
- CANTED COLUMN.** One whose horizontal sections are polygons. In the works of the ancients it is rarely met with. The examples immediately occurring to us are the columns of the portico of Philip of Macedon and of the temple of Cora.
- CANTHARUS.** A fountain or basin of water in the centre of the atrium before the ancient churches, wherein persons washed their faces and hands before they entered. Among the Romans the cantharus of a fountain was the part out of which the water issued.
- CANTHERS or CANTERIL.** In ancient carpentry the common rafters of a roof, whose ends, say some, the mutules of the Doric order represent.
- CANTING.** The cutting away of a part of an angular body at one of its angles, so that its horizontal section becomes thereby the portion of a polygon of a greater number of sides whose edges are parallel from the intersection of the adjoining planes.
- CANTONED BUILDING.** One whose angles are decorated with columns, pilasters, rustic quoins, or any thing projecting beyond the naked of the wall.
- CAP.** A term used in joinery, signifying the uppermost of an assemblage of parts. It is also applied to the capital of a column, the cornice of a door, the capping or uppermost member of the surbase of a room, the handrail of a staircase, &c.
- CAPITAL.** (Lat. *Caput*.) The head or uppermost member of any part of a building; but generally applied in a restricted sense to that of a column or pilaster of the several orders, to which (Sections 3, 4, 5, 6, 7. Chap. I. Book III.) the reader is referred for the differences of their capitals. The chief of the capitals of Eastern and Egyptian architecture are shown in *figs. 58, 59, &c.*
- CAPITAL, ANGULAR.** The modern Ionic capital, whose four sides are alike, showing the volute placed at an angle of  $135^\circ$  on all the faces.
- CAPITAL OF A BALUSTER.** The crowning or head mouldings of it.
- CAPITAL OF A LANTERN.** The covering by which it is terminated; it may be of a bell form, that of a dome, spire, or other regular figure.
- CAPITAL OF A TRIGLYPHE.** The square band which projects over it. In the Roman Doric it has a greater projection than in the Grecian.
- CAPREOLL.** (Lat.) In ancient carpentry the joints or braces of a trussed roof. See *figs. 91, 92.*
- CARACOL.** A term sometimes applied to a staircase in the form of a helix or spiral.
- CARAVANSERA.** Among the Eastern nations a large public building or inn appropriated to the reception and lodgment of travellers by caravans in the desert. Though the caravansera serves the purpose of an inn, there is this essential difference between the two, that in the former the traveller finds nothing either for the use of himself or his cattle, but must carry all his provisions and necessities with him. Caravanseras are also numerous in cities (see an example, *fig. 33.*), where they serve, not only as inns, but as shops, warehouses, and even exchanges.
- CARCASS.** The naked building of a house before it is lathed and plastered, or the floors laid, &c.
- CARCASS FLOORING.** That which supports the boarding, or floor boards, above, and the ceiling below, being a grated frame of timber, varying in many particulars which are described, Book II. Chap. III. Sect. 4., in the body of the work.
- CARCASS ROOFING.** The grated frame of timber work which spans the building, and carries the boarding and other covering. The method of framing the carcass roofing of a building in its varieties is given, p. 544, *et seq.*
- CARDINAL SCAPL.** In ancient Roman joinery, the stiles of doors.
- CARILEPHO.** See *ARCHITECTS*, list of, 83.
- CAROLITIC COLUMN.** One with a foliated shaft.
- CARPENTER.** (Fr. *Charpentier*.) An artificer who cuts, forms, and shapes timbers for the purposes of giving strength and support to the various parts which are of timber, in the construction of buildings.
- CARPENTER'S RULE.** The rule by which carpenters take their dimensions, and also through the aid of a brass slide, which makes it a sliding rule, are enabled to make calculations in multiplication and division, besides other operations.
- CARPENTER'S SQUARE.** An instrument whose stock and blade consists of an iron plate of one piece. One leg is eighteen inches long, and numbered on the outer edge from the exterior angle with the lower part of the figures adjacent to the interior edge. The other leg is twelve inches long, and numbered from the extremity towards the angle; the figures being

read from the internal angle, as on the other side. Each of the legs is about an inch broad. This instrument is not only used as a square, but also as a level and measuring rule.

**CARPENTRY.** (Lat. *Carpentum*, carved wood.) An assemblage of pieces of timber connected by framing, or letting them into each other, as are the pieces of a roof, floor, centre, &c. It is distinguished from joinery by being put together, without the use of any other edge tools than the axe, adze, saw, and chisel, whereas joinery requires the use of the plane. The leading points that require attention in sound carpentry are, — 1. the quality of the timber used; 2. the disposition of the pieces of timber, so that each may be in such direction, with reference to the fibres of the wood, as to be most capable of performing its office properly; 3. the forms and dimensions of the pieces; 4th. the manner of framing the pieces into each other, or otherwise uniting them by means of iron, or other metal. The subject of carpentry in the body of the work is treated under the head of **MECHANICAL CARPENTRY**, Book II. Chap. I. Sect. 11., and of **PRACTICAL CARPENTRY**, in the same Book, Chap. III. Sect. 4.

**CARRARA MARBLE.** The name of a species of white marble obtained at the quarries near the town bearing that name, in the Tuscan States. It was called *marmor lunense* and *ligustum* by the ancients, and differs from the *Parian* marble by being harder in texture, and less bright in colour.

**CARRIAGE.** The timber framework on which the styes of a wooden staircase are supported. See p. 443.

**CARRY UP.** See **BRING UP**.

**CARTOUCH.** (Fr.) A name given to the modillion of a cornice used internally. It is also used to denote a scroll of paper, usually in the form of a tablet, for the reception of an inscription. In Egyptian architecture, applied to those parts of an hieroglyphic inscription enclosed by lines.

**CARVER.** (Ceopfan.) An artificer who cuts wood into various forms and devices. *Carving*, generally, is the art of cutting a body by recession, in order to produce the representation of an object, either in relief, or recessed within the general surface. In this sense it equally applies to the making of intaglios as to that of making cameos.

**CARYATIDES.** Figures used instead of columns for the support of an entablature. See Book I. Chap. II. Sect. 11., and Book III. Chap. I. Sect. 15.

**CASE.** The outside covering of any thing, or that in which it may be enclosed. It is also a term used to denote the carcass of a house.

**CASE BAYS.** The joists framed between a pair of girders in naked flooring. When the flooring joists are framed with one of their ends let into a girder, and the opposite ends let into a wall, they are called *tail-bags*. The extent of the case-bags should not exceed ten feet.

**CASE OF A DOOR.** The wooden frame in which a door is hung.

**CASE OF A STAIR.** The wall surrounding a staircase.

**CASED.** A term signifying that the outside of a building is faced or covered with materials of a better quality. Thus, a brick wall is said to be cased with stone, or with a brick superior in quality to that used in the inner part of the wall.

**CASED SASH FRAMES.** Those which have their interior vertical sides hollow, to admit the weights which balance the sashes hung between them.

**CASEMATE.** A hollow moulding, such as the *cavetto*, which see.

**CASEMENT.** A glazed frame or sash, opening on hinges affixed to the vertical sides of the frame into which it is fitted.

**CASING.** See **LINING**.

**CASINO.** (It. a small house.) A term applied now to a small country house; but formerly to one capable of affording defence on a small scale against an attacking force.

**CASTELLA.** In ancient Roman architecture, reservoirs in which the waters of an aqueduct were collected, and whence the water was conducted through leaden pipes to the several parts of a city.

**CASTELLATED HOUSES.** Those with battlements and turrets, in imitation of ancient castles.

**CASTING.** In carpentry and joinery a term synonymous with *warping*. It means the bending of the surfaces of a piece of wood from their original state, caused either by the gravity of the material, by its being subject to unequal temperature, moisture, or the ununiform texture of the material.

**CASTLE.** (Lat. *Castellum*, or Sax. *Captel*.) A building fortified for military defence; also a house with towers, usually encompassed with walls and moats, and having a donjon or keep in the centre. The principal castles of England at present are those of the Tower of London, of Dover, Windsor, Norwich, &c. At one time those of Harwood, Spofforth, Kenilworth, Warwick, Arundel, and others, might have vied with these in importance. The characteristics of a castle are its *valla* (embankments) and *fossæ* (ditches); from the former whereof the walls rise usually crowned with battlements, and flanked by circular

or polygonal bastions at the angles formed by the walls. These were pierced for gates, with fixed or drawbridges, and towers on each side. The gates of considerable strength were further guarded by descending gratings, called *portcullises*. All the apertures were made as small as they could be, consistent with internal lighting.

The component parts of the castle were — the *fosse* or *moat*, with its bridge; the *barbacan*, which was in advance of the castle, being a raised mound or tower, whose outer walls had terraces towards the castle, with their *bastions*, as above-mentioned; the *gatehouse*, flanked by towers, and crowned with projections called *machicolations*, through which heavy materials, or molten lead, were dropped on the assailants entering the gateway; the *outer ballium*, or *bailey*, or area within the castle, which was separated from the inner ballium by an embattled wall with a gatehouse, and in which the stables and other offices were usually seated; and the *inner ballium*, for the residence of the owner or governor, and his retinue; this, at one corner, or in the centre, had a *donjon*, or *keep tower*, which was the stronghold of the place, and contained a state apartment, a well, and a chapel; the former usually, and the latter frequently, are found in ancient castles. The reader who desires detailed information on this matter is referred to King's *Mun. Antiq.* 4 vols. folio: the *Archæologia*, in many places; Leland's *Collect.* vol. ii. &c. &c.

**CATABASION.** (Gr. *Kαταβασιν*.) A place in the Greek church, under the altar, in which relics are deposited.

CATACOMBS. (Gr. *Kata*, against, and *Koμeος*, a hollow place.) Subterraneous places for burying the dead. The hypogæa, crypta, and cimeteria of the ancients were used for the same purpose. In some cities the excavations for catacombs were of vast extent, and were used for other purposes than those of sepulture; at Syracuse, for instance, the same cavern served for a prison as well as a public cemetery. It has been said, that in the early ages of Christianity they served as places of public worship or devotion. The most celebrated for their extent are those of Rome, Naples, Syracuse, &c.; and the more modern ones of Paris, which have been formed by quarrying for the stone, whereof a great part of the city has been built.

**CATAFALCO.** (It. a scaffold.) A temporary structure of carpentry, decorated with painting and sculpture, representing a tomb or cenotaph, and used in funeral ceremonies. That used at the final interment of Michel Angelo, at Florence, was of a very magnificent description; and, for the art employed on it, perhaps unequalled by any other before or since its employment.

**CATCH DRAIN.** A drain used on the side of a larger open one, or of a canal, to receive the surplus water of the principal conduit.

**CATENARY CURVE.** The mechanical curve formed by a heavy flexible cord or chain of uniform density, hanging freely from the two extremities. Galileo first noticed it, and proposed it as the proper figure for an arch of equilibrium. He, however, imagined that it was the same as the parabola. It was James Bernouilli who first investigated its nature, and its properties were thereafter pointed out by John Bernouilli, Huygens, and Leibnitz. From the first of these mathematicians, the following geometrical method of determining the relations between the parts of a catenary is translated. The catenarean curve is of two kinds, the *common*, which is formed by a chain equally thick or equally heavy in all its points; or *uncommon*, which is formed by a thread unequally thick, that is, which in all its points is unequally heavy, and in some ratio of the ordinates of a given curve. To draw the common catenary mechanically, suspend on a vertical plane a chain of similar and equal links of homogeneous matters, as flexible as possible, from any two points not in a perpendicular line, nor so distant from each other as the length of the chain. Prick the plane through the links as nearly as possible in the middle of the chain, and through the points draw the catenary (*fig.* 1043.). Let the chord *FBD* or *Fbd* be given, and the abscissa *BA* or *bA* intersecting it (*fig.* 1043.) in *B* or *b* at a given angle.

Draw the vertical line BA and FBD or *Fbd* at the given angle on the plane. Fix one end of the chain at F, and from the point D or *d*, with another part of the chain, raise or lower the chain until the lower part coincide with A, and through points, made as before, draw the curve.

To draw a tangent to the catenary: let DBF be a horizontal line, and at right angles to BA from A draw AR equal to the curve DA, obtained as before, and draw BR, which bisect in o. At right angles to BR draw oC intersecting BA continued in C. Draw CR, and make the angle BDT equal to the angle ACR. DT is the tangent required, and BC equals CR; CA is the tension at the point A, or the horizontal draft, which, in a catenary, is in every point the same, and is therefore a constant quantity; as  $DB : BT :: CA : AR$ .

**Fig. 1043.**

or as DB : BT :: the constant quantity CA : AR, equal to the length of the chain AD.

If CH be drawn through C at right angles to BC it is called the directrix, and DH drawn parallel to BC, intersecting the directrix at H, is the tension at the point D, being always equal to the sum of the abscissa and constant quantity. With the centre C and radius = the tension DH at D = CB, cut the tangent at the vertex A in R, then AR is the length of the chain AD.

AC is the semi-axis of an equilateral hyperbola, and also the radius of curvature of a circle equicurved with it and the catenary.

In the triangle CAR, when CA is the radius, then the tension equals CR, the secant of the angle ACR (= BDC). The chain AD equals AR, the tangent of the same angle and the absciss AB equals CR - CA = SR. Hence, ACR being a right-angled triangle, it is manifest that when two of the five quantities, viz. *the angle, the absciss, the length of the chain between the vertex and point of suspension, the constant quantity or tension at the vertex, and the tension at the points of suspension*, are known, the other three may be obtained geometrically, or from a table of tangents and secants.

**CATHARINE WHEEL.** In Gothic buildings an ornamented window or compartment of a window of a circular form, with rosettes or radiating divisions or spokes. In the cathedral at Rheims, the church of St. Ouen at Rouen, in Winchester Cathedral, and the transepts of Westminster Abbey, are specimens, among many others, of this species of ornamental window.

**CATHEDRAL** (Gr. *Καθεδρα*, a seat or throne.) The principal church of a province or diocese, wherein the throne of archbishop or bishop is placed. It was originally applied to the seats in which the bishop and presbyters sat in their assemblies. In after times, the bishop's throne was, however, placed in the centre of the apsis, on each side whereof were inferior seats for the presbyters. In the present day the bishop's throne is placed on one side of the choir, usually on that towards the south.

**CATHETUS.** (Gr. *Καθετος*, let down.) A perpendicular line passing through the centre of a cylindrical body as a baluster or a column. It is also a line falling perpendicularly, and passing through the centre or eye of the volute of the Ionic capital.

**CATTLE SHED, or CATTLE HOUSE.** In agricultural buildings an erection for containing cattle while feeding, or otherwise. The cattle shed is, of course, most economically constructed when built against walls or other buildings. If cattle sheds are built in isolated situations, the expense of a double shed will be much less than that of a single one, to contain the same number of cattle. Buildings of this description should be well ventilated, and be so constructed as to require the least possible labour in supplying the food, and clearing away the dung. The stalls should be placed so as to keep the cattle dry and clean, with sufficient drains to receive the ordure. There should be good provision of air holes in the roof; and, if the building have gables, a window should be placed in each as high as possible with moveable *luffer-boards*, as in granary windows, which may be easily opened and shut by means of a rope attached to a lever connected with them. These precautions will much tend to the health of the cattle, and even preserve the timbers, which in such buildings are peculiarly apt to rot at an early period after their erection, from the constant alternations of dryness and moisture.

**CATTUS.** A moveable shed usually fixed on wheels.

**CAULICOLÆ or CAULICOLI** (Lat. *Caulis*, a stalk.) The eight lesser branches or stalks in the Corinthian capital springing out from the four greater or principal caules or stalks. The eight volutes of the capital of the order in question are sustained by four caules or leaves, from which these caulicolæ or lesser foliage arise. They have been sometimes confounded with the helices in the middle, and by others with the principal stalks whence they arise. Other definitions have been also incorrectly given, but not worth notice here.

**CAULKING or COCKING.** The mode of fixing the tie-beams of a roof or the binding joists of a floor down to the wall-plates. Formerly this was performed by dovetailing in the following manner: — A small part of the depth of the beam at the end of the under side was cut in the form of a dovetail, and to receive it a corresponding notch was formed in the upper side of the wall-plate, across its breadth, making, of course, the wide part of the dovetail towards the exterior part of the wall, so that the beams, when laid in their notches, and the roof finished, would greatly tend to prevent the walls separating, though strained by inward pressure, or even if they should have a tendency to spread, through accidents or bad workmanship. But beams so fixed have been found liable to be drawn to a certain degree out of the notches in the wall-plates from the shrinking of the timber; a more secure mode has therefore been introduced, which obviates all hazard of one being drawn out of the other by any deficiency of seasoning in the timbers, or by any changes of weather.

**CAUSTIC CURVE.** (Gr. *Καυσ*, to burn.) The name given to a curve, to which the rays of light, reflected or refracted by another curve, are tangents. The curve is of two kinds

the *catacaustic* and the *diacaustic* ; the former being caused by reflection, and the latter by refraction.

**CAVÆDIUM.** (Lat.) In ancient architecture an open quadrangle or court within a house. The cavædia described by Vitruvius are of five species : — *Tuscanicum*, *Corinthium*, *Tetrastylon* (with four columns), *Displuviatum* (uncovered), and *Testudinatum* (vaulted). Some authors have made the cavædium the same as the atrium and vestibulum, but they were essentially different.

**CAVE.** (Lat. Cavum.) A hollow place. Perhaps the oldest species of architecture on record.

**CAVEÆ.** (Lat.) In ancient architecture the subterranean cells in an amphitheatre, wherein the wild beasts were confined in readiness for the fights of the arena. In the end the amphitheatre itself (by synecdoche) was called cavea, in which sense it is employed by Ammianus Marcellinus, lib. xxix. cap. i.

**CAVETTO.** (Lat. Cavus.) A hollowed moulding, whose profile is the quadrant of a circle. It is principally used in cornices.

**CEDAR.** (Gr. Κέδρος.) The pinus cedrus of Linnæus, a forest tree little used in this country, except for cabinet work. See p. 484.

**CEILING.** (Lat. Cælum.) The upper horizontal or curved surface of an apartment opposite the floor, usually finished with plastered work. The subject of ceilings is treated of at length in Sect. 24. Chap. I. Book III.

**CEILING FLOOR.** The joisting and ceiling supported by the beams of the roof.

**CEILING JOISTS.** Small beams, which are either mortised into the sides of the binding joists, or notched upon and nailed up to the under sides of those joists. The last mode diminishes the height of the room, but is more easily executed, and is by some thought not so liable to break the plaster as when the ends of the ceiling-joists are inserted into *pulley mortises*.

**CELLER.** See ARCHITECTS, list of, 42.

**CELL.** (Lat. Cella.) In ancient architecture the part of a temple within the walls. It was also called the *naos*, whence our *nave* in a church. The part of a temple in front of the cell was called the *pronaos*, and that in the rear the *posticum*.

**CELLAR.** (Fr. Cellier.) The lower story of a building, when wholly or partly under the level of the ground.

**CEMENT.** (Lat. Cementum.) The medium through which stones, bricks, or any other materials are made to adhere to each other. The different cements for stones and bricks, the most important in building, are treated of in Book II. Chap. II. Sect. II.

**CELTIC ARCHITECTURE.** See Book I. Chap. II. Sect. I.

**CEMETERY.** (Gr. Κεμαί, I lie dead.) An edifice or area where the dead are interred. The most celebrated public cemeteries of Europe are those of Naples, of that in the vicinity of Bologna, of Pisa, and of the more modern ones of Paris, whereof that of Père la Chaise is the principal. That of Pisa is particularly distinguished by the beauty of its form and architecture, which is of early Italian Gothic. It is 490 feet long, 170 feet wide, and 60 feet high, cloistered round the four sides.

**CENOTAPH.** (Gr. Κενος, empty, and Ταφος, a sepulchre.) A monument erected to the memory of a person buried in another place.

**CENTERING.** The temporary woodwork or framing whereon any vaulted work is constructed, sometimes called a *centre*. The principle upon which centering is constructed will be found under the heads of MECHANICAL CARPENTRY, Book II. Chap. I. Sect. 11. and of PRACTICAL CARPENTRY, Book II. Chap. III. Sect. 4.

**CENTRE.** (Lat. Centrum.) In a general sense denotes a point equally remote from the extremes of a line, superficies, or body, or it is the middle of a line or plane by which a figure or body is divided into two equal parts ; or the middle point so dividing a line, plane, or solid, that some certain effects are equal on all its sides. For example, in a circle the centre is every where at equal distance from the circumference ; in a sphere the centre is a point at the same distance from every point in the surface.

**CENTRES OF A DOOR.** The two pivots on which the door revolves.

**CENTROLINEAD.** An instrument for drawing lines converging to a point at any required distance, whether accessible or inaccessible.

**CEROMA.** (Gr.) An apartment in the Gymnasia and baths of the ancients, where the bathers and wrestlers were anointed with oil thickened by wax, as the name imports.

**CESSPOOL, or SESSPOOL.** A well sunk under the mouth of a drain to receive the sediment which might choke up its passage.

**CHAIN TIMEERS.** See BOND.

**CHALCIDICUM.** (Lat.) In ancient architecture a term used by Vitruvius to denote a large building appropriated to the purpose of administering justice, but applied sometimes to the tribunal itself. According to Festus, the name is derived from Chalcis, a city in Eubœa.

**CHALK.** (Germ. Kalk.) Earthy carbonate of lime, found in abundance in Great Britain,

- and, indeed, in most parts of the world. It is insoluble in water, but decomposed by heat, and sometimes used in masonry for the same purposes as limestone.
- CHAMBER.** (Fr. *Chambre*.) Properly a room vaulted or arched, but the word is now generally used in a more restricted sense to signify an apartment appropriated to lodging. With the French the word has a much more extensive meaning; but with us the almost only use of it, beyond what is above stated, is as applied in a palace to the room in which the sovereign receives the subject, which room is called the Presence Chamber.
- CHAMBER OF A LOCK.** In canals the space between the gates in which the vessels rise and sink from one level to another, in order to pass the lock.
- CHAMBER STORY.** That story of a house appropriated for bed-rooms. In good houses it should never be less than ten feet high, in better houses from twelve feet to fifteen feet.
- CHAMBERS.** See **ARCHITECTS**, list of, 300.
- CHAMBRANLE.** (Fr.) An ornamental bordering on the sides and tops of doors, windows, and fireplaces. This ornament is generally taken from the architrave of the order of the building. In window frames the sill is also ornamental, forming a fourth side. The top of a three-sided chambranle is called the *transverse*, and the sides *ascendants*.
- CHAMFER.** (Fr. *Chamfrein*.) The arris of anything originally right-angled cut a slope or bevel, so that the plane it then forms is inclined less than a right angle to the other planes with which it intersects.
- CHAMPAIN LINE.** In ornamental carved work formed of excavations is the line parallel to the continuous line, either ascending or descending.
- CHANCEL.** That part of the eastern end of a church in which the altar is placed. See **CANCELL**. This is the strict meaning; but in many cases the chancel extends much further into the church, the original divisions having been removed for accommodating a larger congregation. The word is also used to denote a separate division of the ancient basilica, latticed off to separate the judges and council from the audience part of the place.
- CHANDRY.** An apartment in a palace or royal dwelling for depositing candles and other lights.
- CHANNEL.** (Fr. *Canal*.) A long gutter or canal sunk below the surface of a body.
- CHANNEL OF THE LARMIER.** See **CANAL OF THE LARMIER**.
- CHANNEL OF THE VOLUTE.** See **CANAL OF THE VOLUTE**.
- CHANNEL STONES.** In paving are those prepared for gutters or channels, serving to collect and run off the rain water with a current.
- CHANTRY.** (Lat. *Cantaria*.) A little chapel in ancient churches with an endowment for one or more priests to say mass for the release of souls out of purgatory. In the fourteenth year of Edward VI. all the chantries in England were dissolved: at this period there were no less than forty-seven attached to St. Paul's Cathedral.
- CHAPEL.** (Lat. *Capella*.) A building for religious worship, erected separately from a church, and served by a chaplain. In Catholic churches, and in cathedrals and abbey churches, chapels are usually annexed in the recesses on the sides of the aisles. These are also called chantries.
- CHAPTER.** The same as **CAPITAL**, which see.
- CHAPELET.** (Fr. *Chapelet*.) A moulding carved into beads, olives, and the like. See **BAGUETTE**.
- CHAPTER HOUSE.** In ecclesiastical architecture the apartment (usually attached) of a cathedral or collegiate church in which the heads of the church or the chapter meet to transact business.
- CHAPTREL.** (Fr.) The same as **IMPOST**, which see.
- CHARGED.** A term used to denote that one member of a piece of architecture is sustained by another. A frieze is said to be *charged* with the ornament cut on it.
- CHARNEL HOUSE.** A place where the bones of the dead are deposited.
- CHARTOPHYLACIUM.** A recess or apartment for the preservation of records or valuable writings.
- CHASE.** An upright indent cut in a wall for the joining another to it, so as to hide light and exclude air.
- CHASE MORTISE, or PULLEY MORTISE.** A long mortise cut lengthwise in one of a pair of parallel timbers, for the insertion of one end of a transverse timber, by making the latter revolve round a centre at the other end, which is fixed in the other parallel timber. This may be exemplified in ceiling joists where the binding joists are the parallel timbers first fixed, and the ceiling are the transverse joists. See **PRACTICAL CARPENTRY**, in the body of the work.
- CHEEKS.** Two upright, equal, and similar parts of any piece of timber-work. Such, for instance, as the sides of a dormer window.
- CHEEKS OF A MORTISE** are the two solid parts upon the sides of the mortise. The thick-

ness of each cheek should not be less than the thickness of the mortise, except mouldings on the stiles absolutely require it to be otherwise.

**CHEESE ROOM.** A room set apart for the reception of cheeses after they are made. The walls should be lined, and fitted up with shelves with one or more stages, according to the size of the room, and proper gangways for commodious passage. In places where much cheese is manufactured, the dairy-room may be placed below, the shelf-room directly above, and lofts may be built over the shelf-room, with trap doors through each floor. This will save much carriage, and will be found advantageous for drying the cheeses.

**CHEQUERS.** In masonry, are stones in the facings of walls, which have all their thin joints continued in straight lines, without interruption or breaking joints. Walls built in this manner are of the very worst description; particularly when the joints are made horizontal and vertical. Those which consist of diagonal joints, or joints inclined to the horizon, were used by the Romans.

**CHESNUT or CHESTNUT.** The *fagus castanea*. A forest tree used in building. See p. 483.

**CHEST.** The same as *caisson*, which see.

**CHEVRON WORK.** A zigzag ornament used in the archivolts of Saxon and Norman arches (see fig. 188.). The outline of chevron work is a conjunction of right lines of equal lengths alternately disposed so as to form exterior and interior angles, and at the same time having all the angular points in the same straight line, or in the same curve line when the chevron work is used for ornamenting arches.

**CHICHELE.** See ARCHITECTS, list of, 146.

**CHIMNEY.** (Fr. *Cheminée*.) The place in a room where a fire is burnt, and from which the smoke is carried away by means of a conduit, called a flue. Chimneys are usually made by a projection from a wall, and recess in the same from the floor ascending within the limits of the projection and the recess. That part of the opening which faces the room is properly called the *fireplace*, the stone or marble under which is called the *hearth*. That on a level with and in front of it is called the *slab*. The vertical sides of the opening are called *jambes*. The head of the fore-plate resting on the jambs is called the *mantel*, and the cavity or hollow from the fireplace to the top of the room is called the *funnel*. The part of the funnel which contracts as it ascends is termed the *gathering*, by some the *gathering of the wings*. The tube or cavity, of a parallelogrammatic form, on the place from where the gathering ceases, up to the top of the chimney, is called the *flue*. The part between the gathering and the flue is called the *throat*. The part of the wall facing the room, and forming one side of the funnel parallel thereto, or the part of the wall forming the sides of the funnels where there are more than one, is the *breast*. In external walls, that side of the funnel opposite the breast is called the *back*. When there is more than one chimney in the same wall, the solid parts that divide them are called *withs*: and when several chimneys are collected into one mass, it is called a *stack of chimneys*. The part which rises above the roof, for discharging the smoke into the air, is called a *chimney shaft*, whose horizontal upper surface is termed the *chimney-top*.

The *coverings* were formerly placed at right angles to the face of the wall, and the chimney was finished in that manner; but Count Rumford showed that more heat is obtained from the fire by reflection when the coverings are placed in an oblique position. He likewise directed that the fire itself should be kept as near to the hearth as possible, and that the throat of the chimney should be constructed much narrower than had been practised, with the view of preventing the escape of so much heated air as happened with wide throats. If the throat be too near the fire, the draught will be too strong, and the fuel will be wasted; if it be too high up, the draught will be too languid, and there will be a danger of the smoke being occasionally beat back into the room.

**CHIMNEY PIECE.** See Book III. Chap. I. Sect. 22.

**CHINESE ARCHITECTURE.** See Book I. Chap. II. Sect. 8.

**CHIP.** A piece of any material cut by an acute-angled instrument.

**CHIROSOPIUS.** See ARCHITECTS, list of, 7.

**CHISEL.** An instrument used in masonry, carpentry, and joinery, and also by carvers and statuary, for cutting either by pressure or by impulse from the blows of a mallet or hammer. There are various kinds of chisels; the principal ones used in carpentry and joinery are the *former*, the *paring chisel*, the *gouge*, the *mortise chisel*, the *socket chisel*, and the *ripping chisel*.

**CHISELED WORK.** In masonry, the state of stones whose surface is formed by the chisel.

**CHIT.** An instrument used for cleaving laths.

**CHOIR.** (Gr. *Xopos*.) The part of a church in which the choristers sing divine service. In former times it was raised separate from the altar, with a pulpit on each side, in which the epistles and gospels were recited, as is still the case in several churches on the Continent. It was separated from the nave in the time of Constantine. In nunneries, the choir is a large apartment, separated by a grate from the body of the church, where the nuns chaunt the service.

**CHORAGIC MONUMENT.** (Gr. *Xopos*.) In Grecian architecture, a monument erected in honour of the choragus who gained the prize by the exhibition of the best musical or theatrical entertainment at the festivals of Bacchus. The choragi were the heads of the ten tribes at Athens, who overlooked and arranged the games at their own expense. The prize was usually a tripod, which the victor was bound publicly to exhibit, for which purpose a building or column was usually erected. The remains of two very fine monuments of this sort, viz. of Lysicrates and Thrasyllus, are still to be seen at Athens. See p. 69.

**CHORD.** In geometry, the straight line which joins the two extremities of the arc of a curve; so called from the resemblance which the arc and chord together have to a bow and its string, the chord representing the string.

**CHRISTMAS.** See ARCHITECTS, list of, 263.

**CHRISTOBOLO.** See ARCHITECTS, list of, 154.

**CHRYSES.** See ARCHITECTS, list of, 63.

**CHURCH.** (Gr. *Kupiakor*, from *Kupios*, Lord.) A building dedicated to the performance of Christian worship. For the general principles on which churches are to be designed see Book III. Chap. III. Sect. 3., also in Book I. Chap. II. Sect. 14. From these latter it will be seen that the basilicæ were the first buildings used for the assembly of the early Christians. Among the first of the churches was that of St. Peter at Rome, about the year 326, nearly on the site of the present church; and it is supposed that the first church of St. Sophia at Constantinople was built somewhat on its model. That which was afterwards erected by Justinian seems, in its turn, to have afforded the model of St. Mark's at Venice, which was the first in Italy constructed with pendentives and a dome, the former affording the means of covering a square plan with an hemispherical vault. The four most celebrated churches in Europe erected since the revival of the arts are, St. Peter's at Rome, which stands on an area of 227,069 feet superficial; Sta. Maria del Fiore at Florence, standing on 84,802 feet; St. Paul's, London, which stands on 84,025 feet, and St. Geneviève at Paris, 60,287 feet. The churches on the Continent are usually ranged under seven classes: *pontifical*, as St. Peter's, where the pope occasionally officiates; *patriarchal*, where the government is in a patriarch; *metropolitan*, where an archbishop is the head; *cathedral*, where a bishop presides; *collegiate*, when attached to a college; *parochial*, attached to a parish; and *conventual* when belonging to a convent. In this country the churches are cathedral, abbey, and parochial.

**CIBORIUM.** (Κιβώριον.) An insulated erection open on each side with arches, and having a dome of ogee form carried or supported by four columns. It is also the coffer or case in which the host is deposited.

**CICCIONE.** See ARCHITECTS, list of, 158.

**CILERY.** The drapery or foliage carved on the heads of columns.

**CILL** (Sax. Cill.) The timber or stone at the foot of a door, &c. *Ground cills* are the timbers on the ground which support the posts and superstructure of a timber building. The name of cill is also given to the bottom pieces which support quarter and truss partitions.

**CIMBIA.** A fillet string, list, or cornice.

**CIMELIARCH.** A name given to the apartment where the plate and vestments are deposited in churches.

**CINCTURE.** The ring, list, or fillet at the top and bottom of a column, which divides the shaft of the column from its capital and base.

**CINQUEFOIL.** An ornament used in the pointed style of architecture; it consists of five euspidated divisions or curved pendants inscribed in a pointed arch, or in a circular ring applied to windows and panels. The cinquefoil, when inscribed in a circle, forms a rosette of five equal leaves having an open space in the middle, the leaves being formed by the open spaces, and not by the solids or cusps.

**CIONE DI ORGAGNA.** See ARCHITECTS, list of, 144.

**CIPPUS.** A small low column, sometimes without a base or capital, and most frequently bearing an inscription. Among the ancients the cippus was used for various purposes; when placed on a road it indicated the distance of places; on other occasions *cippi* were employed as memorials of remarkable events, as landmarks, and for bearing sepulchral epitaphs.

**CIRCLE.** (Lat. *Circulus*.) A figure contained under one line called the circumference, to which all lines drawn from a certain point within it, called the centre, are equal. It is the most capacious of all plain figures.

**CIRCULAR BUILDINGS.** Such as are built upon a circular plan. When the interior also is circular, the building is called a *rotunda*.

**CIRCULAR WORK.** A term applied to any work with cylindric faces.

**CIRCULAR CIRCULAR, or CYLINDRO-CYLINDRIC WORK.** A term applied to any work which is formed by the intersection of two cylinders whose axes are not in the same direction.

The line formed by the intersection of the surfaces is termed, by mathematicians, a *line of double curvature*.

**CIRCULAR ROOFS.** Those whose horizontal sections are circular.

**CIRCULAR WINDING STAIRS.** Such as have a cylindric case or walled enclosure, with the planes of the risers of the steps tending towards the axis of the cylinder.

**CIRCUMFERENCE.** The boundary lines of a circular body.

**CIRCUMSCRIBE.** (Verb.) To draw a line around a figure, or enclose it so that the enclosed shall be touched on all its angles or on its whole circumference by the line or body that encloses it.

**CIRCUMVOLUTIONS.** The turns in the spiral of the Ionic capital, which are usually three, but there are four in the capitals of the temple of Minerva Polias.

**CIRCUS.** (Lat.) In ancient architecture, a straight, long, narrow building, whose length to its breadth was generally as 5 to 1. It was divided down the centre by an ornamented barrier called the *spina*, and was used by the Romans for the exhibition of public spectacles and chariot races. Several existed at Rome, whereof the most celebrated was the Circus Maximus. Julius Caesar improved and altered the Circus Maximus, and that it might serve for the purpose of a naumachia, supplied it with water. Augustus added to it the celebrated obelisk now standing in the Piazza del Popolo. Of this circus no vestiges remain. Besides these at Rome were the circi of Flaminius, near the Pantheon; Agonalis, occupying the site of what is now called the Piazza Navona; of Nero, on a portion whereof St. Peter's stands. Those of Antoninus and Aurelian, no longer even in ruins; but that of Caracalla, which was 738 feet in length, is at the present time sufficiently perfect to exhibit its plan and distribution in the most satisfactory manner. The spectacles of the circus were called the Circensian Games, and consisted of chariot and horse races, of both whereof the Romans were passionately fond, but particularly of the former, which in the times of the emperors excited so great an interest, as to divide the whole population of the city into factions, distinguished by the colours worn by the different charioteers. The disputes of these factions often led to serious disturbances.

**CISSOID.** In geometry a curved line invented by Diocles. Its name is derived from *κισσος*, ivy, from the curve appearing to mount along its asymptote, as ivy climbs on the trunk of a tree. The curve consists of two infinite branches above and below the diameter of a circle, at one of whose ends a tangent being drawn, the curve approaches the tangent without ever meeting it. The curve was invented by its author with a view to the solution of the famous problem of the duplication of the cube, or the insertion of two mean proportionals between two given straight lines. Its mechanical construction may be found in Newton's *Arithmetica Universalis*.

**CIST.** (Gr. *Κίστη*, a chest.) A term used to denominate the mystic baskets used in processions connected with the Eleusinian mysteries. It was originally formed of wicker work, and when afterwards made of metal, the form and texture were preserved in imitation of the original material. When sculptured on ancient monuments, it indicates some connection with the mysteries of Ceres and Bacchus.

**CISTERN.** (Gr. *Κίστη*.) A reservoir for water, whether sunk below or formed of planks of wood above ground. In the construction of an earthen cistern, a well-tempered stratum of clay must be laid as a foundation for a brick flooring, and the bricks laid in terras mortar of Parker's cement. The sides must be built with the same materials; and if in a cellar or other place near a wall a space must be filled with clay, from the foundation to the top of the cistern contiguous to the wall, by which means it will be preserved from injury. Cisterns above ground are usually formed of wooden planks and carried by bearers; but the cistern formed of slates, now much used, is the best for adoption.

**CIVIL ARCHITECTURE.** The art of erecting every species of edifice destined for the use of man, the several matters necessary to the knowledge whereof forms the subject of this work.

**CIVIC CROWN.** A garland of oak leaves and acorns, often used as an architectural ornament.

**CLAMP.** In brick-making a large mass of bricks generally quadrangular on the plan, and six, seven, or eight feet high, arranged in the brick field for burning, which is effected by flues prepared in stocking the clamp, and breeze or cinders laid between each course of bricks. See Book II. Chap. II. sect 9.

**CLAMP.** In carpentry and joinery is a piece of wood fixed to another with a mortise and tenon, or a groove and tongue, so that the fibres of the piece thus fixed cross those of the other, and thereby prevent it from casting or warping.

**CLAMP NAILS.** See NAILS.

**CLASP NAILS.** See NAILS.

**CLATHRI.** In ancient Roman architecture, were bars of iron or wood which were used to secure doors or windows.

**CLAY.** In ordinary language, any earth which possesses sufficient ductility to admit of being kneaded with water. Common clays may be divided into three classes, viz. *mac-tuous*, *meagre*, and *calcareous*. Of these the first is chiefly used in pottery, and the second and third are employed in the manufacture of bricks and tiles.

**CLAYING.** The operation of spreading two or three coats of clay for the purpose of keeping water in a vessel. This operation is also called *puddling*.

**CLAYE.** A term used in some places with the same signification as to stick or to glue.

**CLEAR.** The nett distance between two bodies, where no other intervenes, or between their nearest surfaces.

**CLEAR STORY or CLERE STORY.** The upper vertical divisions of the nave, choir, and transepts of a church. It is *clear* above the roof of the aisles, whence it may have taken its name, but some have derived the name from the *clair* or light admitted through its tier of windows. Nearly all the cathedrals and large churches have *clear stories*, or tiers of arcades, and also of windows over the aisles and triforia. There is no triforium in the priory church of Bath, but a series of large and lofty windows constitute the clear story. The choir at Bristol Cathedral has neither triforium nor clear story.

**CLERATS.** Small wooden projections in tackle to fasten the ropes to.

**CLEAVING.** The act of forcibly separating one part of a piece of wood or other matter from another in the direction of the fibres, either by pressure or by percussion with some wedge-formed instrument.

**CLEFTS.** The open cracks or fissures which appear in wood which has been wrought too green. The carpenter usually fills up these cracks with a mixture of gum and sawdust, but the neatest way is to soak both sides well with the fat of beef broth, and then dip pieces of sponge into the broth and fill up the cracks with them; they swell out so as to fill the whole crack, and so neatly as to be scarcely distinguishable.

**CLEOMENES.** See *ARCHITECTS*, list of, 21.

**CLEOPATRA'S NEEDLES.** A name given to two obelisks on the east of the palace at Alexandria. They are of Thebaic stone and covered with hieroglyphics. One has been thrown down, broken, and lies buried in the sand. The other stands on a pedestal. They were each of a single stone, about sixty feet high and seven feet square.

**CLEPSYDRA.** (Gr. from *Κλεπτα*, to conceal, and *Ύδωρ*, water). A water clock, or vessel for measuring time by the running out of a certain quantity of water, or sometimes of sand, through an orifice of a determinate magnitude. Clepsydras were first used in Egypt under the Ptolemies; they seem to have been common in Rome, though they were chiefly employed in winter. In the summer season sundials were used.

**CLINCHING.** The act of binding and driving backward with a hammer the pointed end of a nail after its penetration through a piece of wood.

**CLINKERS.** Bricks impregnated with nitre and more thoroughly burnt by being nearer the fire in the kiln. See p. 504.

**CLOACÆ.** The name given to the common sewers of ancient Rome for carrying off into the Tiber the filth of the city. The chief of these, called the Cloaca Maxima, was built by the first Tarquin of huge blocks of stone joined together without cement. It consisted of three rows of arches one above another, which at length conjoin and unite together. It began in the Forum Romanum, was 300 paces long, and entered the Tiber between the temple of Vesta and the Pons Senatorius. There were as many principal sewers as there were hills in the city.

**CLOAK-PINS AND RAIL.** A piece of wood attached to a wall, furnished with projecting pegs on which to hang hats, great-coats, &c. The pegs are called *cloakpins*, and the board into which they are fixed, and which is fastened to the wall, is called the *rail*.

**CLOISTER.** (Lat. *Clastrum*.) The square space attached to a regular monastery or large church with a peristyle or ambulatory round, usually with a covered range of building over. The cloister is perhaps, *ex vi termini*, the central square shut in or *closed* by the surrounding buildings. Cloisters are usually square on the plan, having a plain wall on one side, a series of windows between the piers or columns on the opposite side, and arched over with a vaulted or ribbed ceiling. It mostly forms part of the passage of communication from the church to the chapter house, refectory, and other parts of the establishment. In England all the cathedrals, and most of the collegiate churches and abbeys, were provided with cloisters. On the Continent they are commonly appended to large monasteries, and are often decorated with tombs and paintings in fresco.

A common appendage to a cloister was a *lavatory*, or stone trough for water, at which the monks washed their hands previous to entering the refectory.

**CLOSER.** The last stone in the horizontal length of a wall, which is of less dimensions than the rest to close the row. Closers in brickwork, or pieces of bricks (or *bats*), less or greater than half a brick, that are used to close in the end of a course of brickwork. In English as well as Flemish bond, the length of a brick being but nine inches, and its width four inches and a half, in order that the vertical joints may be broken at the end of the first stretcher, a quarter brick (or *bat*) must be interposed to preserve the con-

tinuity of the bond, this is called a *queen-closer*. A similar preservation of the bond may be obtained by inserting a three-quarter bat at the angle in the stretching course; this is called a *king-closer*. In both cases an horizontal lap of two inches and a quarter is left for the next header. See Book II. Chap. III. Sect. 2.

**CLOSE STRING.** In dog-legged stairs, a staircase without an open newel.

**CLOSE OR CLOOS.** See ARCHITECTS, list of, 153.

**CLOSET.** A small apartment frequently made to communicate with a bed-chamber, and used as a dressing room. Sometimes a closet is made for the reception of stores, and is then called a *store closet*.

**CLOUGH OR CLOYSE.** The same as *paddle, shuttle, sluice, or penstock*. A contrivance for retaining or letting out the water of a canal, pond, &c.

**CLOUGH ARCHES OR PADDLE-HOLES.** Crooked arches by which the water is conveyed from the upper pond into the chamber of the lock of a canal on drawing up the *clough*.

**CLOUT NAILS.** See NAILS.

**CLUSTERED.** The combination of several members of an order penetrating each other.

**CLUSTERED COLUMNS.** Several slender pillars or columns attached to each other so as to form one. In Roman architecture the term is used to denote two or four columns which appear to intersect each other, at the angle of a building or apartment, to answer to each return.

**COARSE STUFF.** In plastering, a mixture of lime and hair used in the first coat and floating of plastering. In floating more hair is used than in the first coat.

**COAT.** A thickness or covering of plaster or other work done at one time.

**COBARRUBIAS.** See ARCHITECTS, list of, 210.

**COR-WALLS.** Such as are formed of mud mixed with straw, not uncommon in some districts of England, but the best are to be found in Somersetshire.

**COCCEIUS.** See ARCHITECTS, list of, 38.

**COCKING OR COGGING.** See CAULKING.

**COCKLE STAIRS.** A term sometimes used to denote a winding staircase.

**CŒNACULUM.** (Lat.) In ancient Roman architecture, an eating or supper room. In the early period of their history, when the houses rarely consisted of more than two stories, it denoted generally the upper story. The word also signified lodgings to let out for hire, and also the upper stories of the *circi*, which were divided into small shops or rooms.

**CŒNATIO.** An apartment in the lower part of the Roman houses, or in a garden, to sup or eat in. From Suetonius it would appear that it denoted a banqueting and summer house. In the Laurentine Villa a large *cœnatio* is described by the younger Pliny, and it seems, from the description, that it was placed in the upper part of a lofty tower.

**COFFER.** (Sax. *Corpe*.) A sunk panel in vaults and domes, and also in the soffit or under side of the Corinthian and Composite cornices, and usually decorated in the centre with a flower. But the application of the term is general to any sunk panel in a ceiling or soffit.

**COFFER DAM.** A case of piling, water-tight, fixed in the bed of a river, for the purpose of excluding the water while any work, such as a wharf, wall, or the pier of a bridge, is carried up. A coffer dam is variously formed, either by a single enclosure or by a double one, with clay, chalk, bricks, or other materials between, so as effectually to exclude the water. The coffer dam is also made with piles only driven close together, and sometimes notched or dove-tailed into one another. If the water be not very deep, piles may be driven at a distance of five or six feet from each other, and grooved in the sides with boards let down between them in the grooves. For building in coffer dams, a good natural bottom of gravel or clay is requisite, for though the sides be made sufficiently water-tight, if the bed of the river be loose, the water will ooze up through it in too great quantities to permit the operations to be carried on. It is almost unnecessary to inculcate the necessity of the sides being very strong and well-braced on the inside to resist the pressure of the water.

**COGGING.** See CAULKING.

**COIN.** (Fr.) The same as *quoins*. The angle formed by two surfaces of a stone or brick building, whether external or internal, as the corner formed by two walls, or of an arch and wall, the corner made by the two adjacent sides of a room, &c.

**COL.** See ARCHITECTS, list of, 175.

**COLISEUM.** The name given to the amphitheatre built (A. D. 72) by Vespasian. See body of the work, p. 94.

**COLLAR or COLARINO.** (It.) A ring or cincture; it is another name for the astragal of a column. It is sometimes called the neck, *gorgerin*, or *hypotrachelium*.

**COLLAR BEAM.** A beam used in the construction of a roof above the lower ends of the rafters or base of the roof. The tie beam is always in a state of extension, but the collar beam may be either in a state of compression or extension as the *principal rafters* are

with or without tie beams. In trussed roofs, collar beams are framed into queen posts; in common roofs, into the rafters themselves.

In general, trusses have no more than one collar beam; yet, in very large roofs, they may have two or three collar beams besides the tie beam. The collar beam supports or trusses up the sides of the rafters, so as to keep them from sagging without any other support, but then the tie beam would be supported only at its extremities. In common purlin roofing, the purlins are laid in the acute angles between the rafters and the upper edges of the collar beams. See p. 546.

**COLLEGE.** An establishment properly so termed for the education of youth in the higher branches of study. See Book III. Chap. III. Sect. 8.

**COLONELLI.** (It.) The Italian name for the posts employed in any truss framing.

**COLONNADE.** (It. *Colonnata*.) A range of columns. If the columns are four in number, it is called *tetrastyle*; if six in number, *hexastyle*; when there are eight, *octastyle*; when ten, *decastyle*; and so on, according to the Greek numerals. When a colonnade is in front of a building it is called a *portico*, when surrounding a building a *peristyle*, and when double or more *polystyle*. The colonnade is moreover designated according to the nature of the intercolumniations introduced as follows: *pycnostyle*, when the space between the columns is one diameter and a half of the column; *systyle*, when it is of two diameters; *eustyle*, when of two diameters and a quarter; *diastyle*, when three, and *araostyle* when four.

**COLUMBARIUM.** (Lat.) A pigeon-house. The plural of the word (*columbaria*) was applied to designate the apertures formed in walls for the reception of cinerary urns in the ancient Roman cemeteries.

**COLUMELLA.** A name sometimes used for balusters.

**COLUMN.** (Lat. *Columna*.) Generally any body which supports another in a vertical direction. For an account of the columns used in the five orders, see Book III. Chap. I. Sects. 2, 3, 4, 5, 6, and 7. There are various species of columns, as *twisted*, *spiral*, and *rusticated*. *Cabled* or *rudented* columns are such as have their flutings filled with cables or astragals to about one third of the height. *Carolitic* columns have their shafts foliated. Columns were occasionally used as monuments, as the Trajan and Antonine columns at Rome, and the Monument in London. By the side of the Halle au Blé at Paris there is a *gnomonic* column for showing the time, erected by Catharine di Medici. The *Columna Bellica* at Rome was near the temple of Janus, and at it the consul proclaimed war by throwing a javelin towards the enemies' country. The *chronological* column was rather historical, bearing an inscription to record an event. The *crucifera* column is one bearing a cross; the *funereal* one, an urn; the *zoophoric*, an animal; and the *itinerary* one pointed out the various roads diverging from its site. There was among the Romans what was called a *lactea* column, which stood in the vegetable market, and contained on its pedestal a receptacle for infants abandoned by their parents. (Juvenal, *Sat.* vi.) On the *legal* column were engraved the laws; the *boundary* or *limitative* column marked the boundary of a province; the *manubial* column was for the reception of trophies or spoils; and the *rostral* column, decorated with prows of ships, was for the purpose of recording a naval engagement. The *triumphal* column was erected in commemoration of a triumph, and the *sepulchral* one was erected on a tomb. The *milliarium aureum*, or *milliary* column of the Romans, was originally a column of white marble, erected by Augustus in the Forum, near the temple of Saturn. From it the distances from the city were measured. It is a short column with a Tuscan capital, having a ball of bronze (formerly gilt for its finish) at top, and is still preserved in the Capitol.

**COMBINATION OF THE PARTS OF BUILDINGS.** See Book III. Chap. III. Sect. 1., and Book III. Chap. II. Sects. 4. and 6.

**COMITIUM.** (Lat.) A building which stood in the Roman Forum, wherein assemblies of the people were held. It occupied the whole space between the Palatine Hill, the Capitol, and the Via Sacra.

**COMMISSURE.** (Lat.) The joint between two stones, or the application of the surface of one stone to the surface of another.

**COMMON CENTRING.** Such as is constructed without trusses, but having a tie beam at its ends. Also that employed in straight vaults.

**COMMON JOISTS.** Those in single naked flooring to which the boards are fixed. They are also called *boarding joists*, and should not exceed one foot apart.

**COMMON RAFTERS.** Those in a roof to which the boarding or lathing is attached.

**COMMON ROOFING.** That which consists of common rafters only, which bridge over the purlins in a strongly framed roof.

**COMMUNICATION DOORS.** Those which, when open, throw two apartments into one.

**COMPARTED.** (Fr. *Compartin*, to divide.) That which is divided into several parts is said to be *comparted*.

**COMPARTMENT.** The distribution of the ground plot of an edifice into the various passages and apartments.

- COMPARTMENT.** A subdivisional part, for ornament, of a larger division. To this alone is the term properly applicable.
- COMPARTMENT CEILING.** One divided into panels, which are usually surrounded by mouldings.
- COMPARTMENT TILES.** An arrangement of varnished red and white tiles on a roof.
- COMPASS SAW.** One for dividing boards into curved pieces; it is very narrow and without a back.
- COMPASSES.** (Fr. *Compas*.) A mathematical instrument for drawing circles and measuring distances between two points. *Common compasses* have two legs, moveable on a joint. *Triangular compasses* have two legs similar to common compasses, and a third leg fixed to the bulb by a projection, with a joint so as to be moveable in every direction. *Beam compasses*, which see, are used for describing large circles. *Proportional compasses* have two pair of points moveable on a shifting centre which slides in a groove, and thereby regulates the proportion that the opening at one end bears to that of the other. They are useful in enlarging or diminishing drawings.
- COMPLEMENT.** The number of degrees which any angle wants of a right angle. The complement of a parallelogram is two lesser parallelograms, made by drawing two right lines parallel to the sides of the greater through a given point in the diagonal.
- COMPLUVIUM.** (Lat.) An area in the centre of the ancient Roman houses, so constructed that it might receive the waters from the roofs. It is also used to denote the gutter or eave of a roof.
- COMPO.** A name often given to Parker's cement.
- COMPOSITE ARCH.** The same as the pointed or lancet arch.
- COMPOSITE NUMBERS.** Such as can be divided by some other number greater than unity; whereas *prime numbers* admit of no such divisor.
- COMPOSITE ORDER.** See Book III. Chap. I. Sect. 7., and Book I. Chap. II. Sect. 13.
- COMPOSITION, ARCHITECTURAL.** For general principles, see Book III. Chap. II. Sect. 1.
- COMPOSITION OF FORCES.** The combination or union of several forces for determining the result of the whole. See p. 381.
- COMPOUND INTEREST.** See p. 280. 856.
- COMPRESSIBILITY.** The quality of bodies which permits of their being reduced to smaller dimensions. All bodies, in consequence of the porosity of matter, are compressible, but liquids resist compression with immense force.
- CONCAMERATA SUDATIO.** An apartment in the ancient gymnasium, between the *laconicum* or stove, and the warm bath. To this room the racers and wrestlers retired to wipe off the sweat from their bodies.
- CONCAMERATE.** (Lat.) To arch over.
- CONCAVITY.** (Lat. *Concavus*, hollow.) Of a curve line is the side between the two points of the curve next its chord or diameter. The concavity of a solid is such a curved surface, that if any two points in it be taken, the straight line between them is in a void space, or will coincide in only one direction with the surface.
- CONCENTRIC.** (Lat.) Having a common centre, as are the radii of a circle.
- CONCHOID OF NICOMEDES.** A name given to a curve invented by that mathematician for solving the two famous problems of antiquity — the duplication of the cube, and the trisection of an angle. It continually approaches a straight line without meeting it, though ever so far produced.
- CONCRETE.** (Lat. *Concrescere*.) To coalesce in one mass. A mass composed of stone chippings or ballast, cemented together through the medium of sand and lime, and usually employed in making foundations where the soil is of itself too light or boggy, or otherwise insufficient for the reception of the walls. See Book II. Chap. II. Sect. 11.
- CONDUIT.** (Fr.) A long narrow walled passage underground, for secret communication between different apartments. It is a term also used to denote a canal or pipe for the conveyance of water, and is also applied to the structure to which it is conveyed for delivery to the public.
- CONE.** (Gr. *Konos*.) A solid body, having a circle for its base, and terminating in a point called its vertex; so that a straight line drawn from any point in the circumference of the base to the vertex will coincide with the convex surface. If the axis or straight line drawn from the centre of the base to the vertex be perpendicular to the base, it is termed a *right cone*; if not, it is an *oblique cone*.
- CONFESSONAL.** (Lat.) In Catholic churches the small cell wherein the priest sits to hear the confession of, and give absolution to, the penitent. It is usually constructed of wood and in three divisions, the central one whereof has a seat for the convenience of the priest.
- CONFIGURATION.** The exterior form or superficies of any body.
- CONGE.** (Fr.) The same as *APOPHYGE*, which see.
- CONIC SECTIONS.** The figures formed by the intersections of a plane with a cone. They

are five in number : a triangle, a circle, an ellipse, a parabola, and an hyperbola ; the three last, however, are those to which the term is usually applied. See Book II. Chap. I. Sect. 5.

**CONICAL ROOF.** One whose exterior surface is shaped like a cone.

**CONISTERIUM.** (Gr. *Κονιστήριον*.) In ancient architecture, a room in the gymnasium and palaestra, wherein the wrestlers, having been anointed with oil, were sprinkled over with dust, that they might lay firmer hold on one another.

**CONJUGATE DIAMETERS.** The diameters in an ellipsis or hyperbola parallel to tangents at each other's extremities.

**CONOID.** (Gr. *Κονοειδής*.) Partaking of the figure of a cone. A figure generated by the revolution of a conic section round one of its axes. There are three kinds of conoids, the *elliptical*, the *hyperbolical*, and the *parabolical*, which are sometimes otherwise denominated by the terms *ellipsoid* or *spheroid*, *hyperboloid*, and *paraboloid*.

**CONSERVATORY.** A building for preserving curious and rare exotic plants. It is made with beds of the finest composts, into which the trees and plants on being removed from the greenhouse, and taken from the tubs and pots, are regularly planted.

With respect to its construction, it is very similar to the greenhouse, but it must be more spacious, loftier, and finished in a superior style. The sides, ends, and roofs should be of glass, for the free admission of light, and for protection of the plants. It should be, moreover, seated on a dry spot, so as to receive during the day as much of the sun's heat as possible. It is to be provided with flues or boiling water pipes, to raise the temperature when necessary ; there must also be contrivances for introducing fresh air when required. In summer time the glass roofs are taken off and the plants exposed to the open air ; but these are restored always, if taken off, on the slightest indication of frost. The chief point in which conservatories differ from greenhouses is, that in the latter, the plants and trees stand in pots placed upon stages, whereas, in the former, they are planted in beds of earth surrounded with borders. See GREENHOUSE.

**CONSOL.** The same as ANCONES, which see.

**CONSTRUCTION.** Literally, the building up from the architect's designs ; but amongst architects it is more particularly used to denote the art of distributing the different forces and strains of the parts and materials of a building in so scientific a manner as to avoid failure and insure durability. The second book of this work is devoted to the subjects involved in the science of construction.

**CONSTRUCTIVE CARPENTRY, or PRACTICAL CARPENTRY.** See Book II. Chap. III. Sect. 4.

**CONTACT.** (Lat. *Contactus*.) In geometry the touching any figure by a line or plane which may be produced either way without cutting it.

**CONTENT.** (Lat. *Contentus*.) The area or superficial quantity contained in any figure.

**CONTEXTURE.** (Lat. *Contextus*.) The inter-disposition, with respect to each other, of the different parts of a body.

**CONTIGNATIO.** In Roman carpentry the same as that which we term *naked flooring*.

**CONTINUED.** A term used to express anything uninterrupted. Thus, an attic is said to be continued when not broken by pilasters ; a pedestal is continued when, with its mouldings and dado or die, it is not broken under the columns ; so of a socle, &c.

**CONTOUR.** (It. *Contorno*.) The external lines which bound and terminate a figure.

**CONTRACT.** An agreement attached to a specification for the performance of certain works.

**CONTUCCIO.** See ARCHITECTS, list of, 190.

**CONVENT.** (Lat. *Conventus*.) A building for the reception of a society of religious persons.

**CONVENTUAL CHURCH.** One attached or belonging to a convent.

**CONVERGENT LINES.** Such as, if produced, will meet.

**CONVEX.** (Lat. *Convexus*.) A form which swells or rounds itself externally. A convex rectilinear surface is a curved surface, in which a point being taken, a right line passing through it can only be drawn in one direction.

**COPING.** (Dutch, *Cop*, the head.) The highest and covering course of masonry or brickwork in a wall. Coping equally thick throughout is called *parallel coping*, and ought to be used only on inclined surfaces, as on a gable, for example, or in situations sheltered from the rain, as on the top of a level wall, which it is intended to cover by a roof. Coping thinner on one edge than on the other serves to throw off the water on one side of the wall, and is called *feather-edged coping*. Coping thicker in the middle than at the edges is called *saddle-backed coping*. This, of course, delivers each way the water that falls upon it. It is commonly used on the walls of a sunk area, on dwarf walls carrying an iron railing, and in the best constructed fence walls. In Gothic architecture, coping is either inclined upon the faces or plumb ; in the former case the sides of the vertical section are those of an equilateral triangle with an horizontal base. It is sometimes in one inclined plane, terminated at top by an astragal, and at others in two inclined planes parallel to each other, whereof the upper is terminated at top by an astragal, and projects

before the lower, which, like that on one inclined plane, changes its direction at the bottom into a narrow vertical plane projecting before the level soffit before the parapet. The inclined coping is occasionally used without the astragal. The soffit of a projection is said to cope over when it slants downwards from the wall.

**COPPER.** (Cuprum, a corruption of Cyprium, having been originally brought from the island of Cyprus.) One of the metals used in building, but not now to the extent to which it was employed a few years back. See Book II. Chap. II. Sect. 7.

**CORBELL.** (Lat. Corbis, a basket.) A carved basket, with sculptured flowers and fruit, used as the finishing of some ornament. The name is given to the basket placed on the heads of caryatides, under the soffit of the architrave cornice. The term is also applied to the bell of the Corinthian capital.

**CORBELS,** in castellated and Gothic architecture, are a range of stones projecting from a wall for the purpose of supporting a parapet or the superior projecting part of the wall. Two of their sides are vertical planes perpendicular to the face of the wall; the fronts are variously moulded. They perform the same office as the modillions of an order, but the term is confined to the pointed style.

The word corbel is sometimes used to denote a niche or hollow in a wall for the reception of a statue or bust. There is also another sense in which it is used, namely, to signify a horizontal range of stones or timber fixed in a wall or in the side of a vault, serving to sustain the timbers of a floor or of a vault. In old buildings many of the timber floors or contignations were thus supported.

**CORBEL STEPS** are certain steps in the gables of old buildings.

**CORBEL TABLE.** A series of semicircular intersecting arches for carrying a battlement, parapet, or cornice, and resting on corbels. Also any projection borne by corbels.

**CORDON.** The edge of a stone on the outside of a building.

**CORE.** The interior part of anything. In walls of masonry there should be thorough stones at regular intervals, for strengthening the core, which is commonly composed of rubble stones, or, when they are not procurable, two bond stones lapped upon each other may be used, one from each face of the wall. Instead of each thorough stone we may lay two stones level on the upper bed, and one large stone in the core lapped upon both, observing that the tails of the two lower stones be right-angled; by this means the two sides of the wall will be completely tied together.

The core of a column is a strong post of some material inserted in its central cavity when of wood.

**CORINTHIAN ORDER.** See Book III. Chap. I. Sect. 7., and Book I. Chap. II. Sect. 1.

**CORNICE.** (Fr. Corniche.) Any moulded projection which crowns or finishes the part to which it is affixed. Thus, we speak of the cornice of an order, of a pedestal, of a pier, door, window, house, &c. The cornice of an order is a secondary member of the order itself, being the upper subdivision of the entablature.

**CORONA.** (Lat.) A member of the cornice, with a broad vertical face, and usually of considerable projection. The solid, out of which it is formed, is commonly recessed upwards from its soffit, and this part by the English workmen is called the *drip*, because it facilitates the fall of the rain from its edge, by which the parts below it are sheltered. The situation of the corona is between the cymatium above, and the bed-moulding below. See Book III. Chap. I. Sect. 18.

**CORPS.** A French term, which signifies the projecting part of a wall, and intended to form the ground for some decoration.

**CORRIDOR.** (It. Corridore.) A gallery or passage round a quadrangle leading to the various apartments. Also, any gallery of communication to them.

**CORSA.** (Lat.) In ancient architecture, the name given by Vitruvius to any platband or square fascia whose height is greater than its projection.

**CORTILE.** (It.) A small court or area, quadrangular or curved, in a dwelling-house, which is surrounded by the buildings of the house itself.

**COSSUTIUS.** See ARCHITECTS, list of, 29.

**COTTAGE.** (Sax. Cot.) A small house or dwelling for a poor person. See Book III. Chap. III. Sect. 24.

**COTTE.** See ARCHITECTS, list of, 272.

**COUCY.** See ARCHITECTS, list of, 127.

**COUNTER DRAIN.** A drain parallel to a canal or embanked water-course, for collecting the soakage water by the side of the canal or embankment to a culvert or arched drain under the canal, by which it is conveyed to a lower level.

**COUNTERFORT.** (Fr.) A buttress or pier built against and at right angles to a wall to strengthen it.

**COUNTER GAUGE.** In carpentry, the measure of the joints by *transferring*, as, for instance, the breadth of a mortise to the plan on the other timber, where the tenon is to be made to adapt them to each other.

**COUNTER LATH.** One placed between every couple of gaugedones.

**COUNTERPARTS** of a building are the similar and equal parts of the design on each side of the middle of the edifice.

**COUNTER SINK.** The sinking a cavity in a piece of timber or other material to receive a projection on the piece which is connected with it, as for the reception of a plate of iron or the head of a screw or bolt.

**COUPLED COLUMNS.** Those arranged in pairs half a diameter apart. See 267. 2605—2608.

**COUPLES.** A term used in the north to signify rafters framed together in pairs with a tie fixed above their feet. The *main couples* answer to the trusses.

**COURSE.** (Lat. *Cursus*.) A continued level range of stones or bricks of the same height throughout the face or faces of a building. *Coursed masonry* is that therefore wherein the stones are laid in courses. The *course of the face of an arch* is the face of the arch stones, whose joints radiate to the centre. The *course of a plinth* is its continuity in the face of the wall. A *bond course* is that whose stones are inserted into the wall farther than either of the adjacent courses, for the purpose of binding the wall together. A *coursing joint* is the joint between two courses.

**COURSE, HEADING,** in brickwork, is that in which the bricks are laid with their short sides towards the face.

**COURSE, STRETCHING,** is that in which the bricks are all laid lengthwise.

**COURT.** (Fr. *Cour*.) An uncovered area before or behind the house or in the centre of it, in which latter case it is often surrounded by buildings on its four sides.

**COURTS OF LAW.** See Book III. Chap. III. Sect. 6.

**COUSSINET.** (Fr. *Cushion*.) A stone placed upon the impost of a pier for receiving the first stone of an arch. Its bed is level below, and its surface above is inclined for receiving the next voussoir of the arch.

The word is also used for the part of the Ionic capital between the abacus and quarter round, which serves to form the volute, and it is in the capital thus called because its appearance is that of a cushion or pillar seemingly collapsed by the weight over it, and is bound with a strap or girdle called the *baltheus*.

**COVE.** Any kind of concave moulding or vault; but the term, in its usual acceptation, is the quadrantal profile between the ceiling of a room and its cornice.

**COVE BRACKETING.** The wooden skeleton for the lathing of any cove; but the term is usually applied to that of the quadrantal cove, which is placed between the flat ceiling and the wall.

**COVER.** That part of a slate which is hidden or covered.

**COVER WAY.** In roofing, the recess or internal angle left in a piece of masonry or brickwork to receive the roofing.

**COVING,** in old buildings, the projection of the upper stories of houses over the lower ones.

**COVING OF A FIRE-PLACE.** See CHIMNEY.

**COW-HOUSE.** A building for the protection of cows from the inclemencies of the season.

**COZZO, PIETRO DI.** See ARCHITECTS, list of, 98.

**CRAB.** A species of crane much used by masons for raising large stones; it is a wheel and axle mounted on a pair of sloping legs, three or four feet apart, the legs being inserted into a frame at the base, whereon, opposite to the weight to be raised, a load may be placed for gaining so great an amount of leverage as to overcome the weight to be raised. The rope for the tackle works round the axle, which is turned by pinion wheels to gain power.

**CRADLE.** A name sometimes given to a centering of ribs and lattice for turning culverts.

**CRADLE VAULT.** A term used, but improperly, to denote a cylindric vault.

**CRADLING.** The timber ribs and pieces for sustaining the lathing and plastering of vaulted ceilings. The same term is applied to the wooden bracketing for carrying the entablature of a shop front.

**CRAMP.** An iron instrument about four feet long, having a screw at one end, and a moveable shoulder at the other, employed by carpenters and joiners for forcing mortise and tenon work together.

**CRAMPEN OF CRAMP IRON,** usually called for shortness *cramp*, a piece of metal, bent at both extremities towards the same side, for fastening stones together. When stones are to be connected with a greater strength than that of mortar, a chain or bar of iron with different connecting knobs is inserted in a cavity, cut on the upper side of a course of stones across the joints, instead of single cramps across the joints of each two stones. Cramps are commonly employed in works requiring great solidity; but in common works they are applied chiefly to the stones of copings and cornices, and generally in any external work upon the upper surface or between the beds of the stone. All external work, liable to the injuries which weather inflicts, should be cramped. The most secure mode of fixing cramps is to let them into the stone their whole thickness, and to run them with lead; but in slight works it is sufficient to bed them in plaster, as is practised in chimney-pieces. In modern buildings iron is chiefly used. The practice is bad,

from the liability of iron to rust and exfoliate: hence cast-iron is better than wrought, and should be of somewhat larger size than when wrought iron is employed. The Romans wisely used cramps of bronze, a material far better than either cast or wrought iron.

**CRAMPOONS.** Hooked pieces of iron, something like double calipers, for raising timber or stones.

**CRANE.** (Sax. Cpan.) A machine for raising heavy weights, and depositing them at some distance from their original place. The crane may be constructed of immense power, and is generally worked by human strength.

**CRANE-HOUSE.** A building erected for the shelter of a crane. By the Building Act it is most absurdly required to be of brick.

**CRAPAUDINE DOORS.** Those which turn on pivots at top and bottom.

**CREASING OF TILE CREASING.** Two rows of plain tiles placed horizontally under the coping of a wall, and projecting about an inch and a half on each side to throw off the rain water.

**CRENELLE.** In Gothic architecture, the opening in an embattled parapet.

**CRESCENT.** A building, or rather a series of buildings, which on the plan is disposed in the arc of a circle.

**CREST TILE.** That on the ridge of a house. In Gothic architecture, crest tiles are those which, decorated with leaves, run up the sides of a gable or ornamented canopy.

**CRIB.** The rack of a stable; sometimes applied to the manger. It is used also to express any small habitation; and moreover the stall or cabin of an ox.

**CROCKET.** (Fr. *Croc*, a hook.) One of the small ornaments usually placed on the angles of pinnacles, pediments, canopies, &c., in Gothic architecture, and most commonly disposed at equal distances from each other. The crocket seems to have had for type the buds and boughs of trees in the spring season, from the great resemblance it bears to those periodical productions: examples, moreover, of the same ornament have great resemblance to the first stage of the leaves when the buds begin to open; sometimes, however, animals are substituted in the place of leaves.

**CROMLECHS.** A mass of large flat stones laid across others in an upright position. Examples of cromlechs are found in Wales, Devonshire, Cornwall, and many exposed districts of England. For a further account of the cromlech, the reader may turn to Book I. Chap. II. Sect. 1.

**CROSETTES.** (Fr.) The same as *ancones*, which see. In architectural construction the term is applied to the small projecting pieces as  in arch stones, which hang upon the adjacent stones.

**CROSS.** (Lat. *Crux*.) A figure consisting of four branches at right angles to each other, or a geometrical one, consisting of five rectangles, each side of one rectangle being common with one side of each of the other four. It is a figure more particularly used for the plans of churches than for those of other edifices. In ecclesiastical architecture, there are two kinds of plans having the form of a cross. The first is that wherein all the five rectangles are equal, or wherein each of the four wings is equal to the middle part formed by the intersection: this form is called a *Greek cross*. The second has only the two opposite wings equal, the other two are unequal, and the three rectangles in the direction of the unequal parts are of greater length than the three parts in the direction of the equal parts: this is the *Latin cross*. The middle part in each direction is common.

**CROSS,** in Gothic architecture, an erection of various kinds, which may be classed as follows:—those used for marking boundaries, those which were memorials of remarkable events, monumental or sepulchral, as that at Waltham, and others of that nature; for preaching, as the ancient St. Paul's Cross; and market crosses, as at Winchester, Leighton Buzzard, &c.

**CROSS-BANDED.** A term applied to handrailing, which is said to be cross-banded, when a veneer is laid upon its upper side, with the grain of the wood crossing that of the rail, and the extension of the veneer in the direction of its fibres is less than the breadth of the rail.

**CROSS BEAM.** A large beam going from wall to wall, or a girder that holds the sides of the house together.

**CROSS GARNETS.** Hinges having a long strap fixed close to the aperture, and also a cross part on the other side of the knuckle, which is fastened to the joint.

**CROSS-GRAINED STUFF.** Wood which has its fibres in a contrary direction to the surface, and which consequently cannot be perfectly smoothed by the operation of the plane, without turning either the plane or the stuff. This defect arises from a twisted disposition of fibres while in the act of growing.

**CROSS SPRINGERS.** The ribs in the pointed style that spring from the diagonals of the pillars or piers.

**CROSS VAULTING.** That formed by the intersection of two or more simple vaults. When

each of the simple vaults rises from the same level to equal heights, the cross vaulting is denominated a *groin*; but when one of the simple vaults is below the other, the inter section is called an *arch* of that particular species which expresses both the simple arches. For example, if one cylinder pierce another of greater altitude, the arch so formed is termed a *cylindro-cylindric arch*; and if a portion of a cylinder pierce a sphere of greater altitude than the cylinder, the arch is called a *sphero-cylindric arch*, and thus for any species of arch whatever, the part of the qualifying word which ends in *o* denotes the simple vault having the greater altitude, and the succeeding word the other of less altitude.

**CROW.** A bar of iron used in bricklaying, masonry, and quarrying, and serving usually as a lever in its employment.

**CROWN.** (Lat. *Corona*.) The uppermost member of any part. Thus, the upper member of a cornice, including the corona and the members above it, is so called.

**CROWN OF AN ARCH.** The most elevated line or point that can be assumed in its surface.

**CROWN or JOGGLE POST,** is the same as *king post*, being the truss post that sustains the tie beam and rafters of a roof.

**CROWN GLASS.** The finest sort of window glass. See Book II. Chap. II. Sect. 11.

**CROWNING.** The part that terminates upwards any piece of architecture, as a cornice, pediment, &c.

**CRYPT.** (Gr. *Κρυπτόν*, I hide.) The under or hidden part of a building. It is used also to signify that part of the ancient churches and abbeys appropriated below to the monuments of deceased persons.

**CRYPTO-PORTICUS.** In ancient architecture a concealed portico, also one that for coolness is enclosed on every side. Some of them were sunk some way into the ground. It also is a term applied to subterranean or dark passages and galleries in the Roman villas, often used as cool sitting rooms.

**CUBE.** (Gr. *Κύβος*, a die.) A solid bounded by six square sides. It is also, from its six sides, called *hexahedron*.

**CUBICULUM.** (Lat.) A chamber. A distinction is made by Pliny between the *cubiculum* and the *dormitorium*. The name was also applied to the royal pavilion or tent which was built in the circus or amphitheatre for the reception of the emperors.

**CUBIT.** A linear measure, in ancient architecture, equal to the length of the arm from the elbow to the extremity of the middle finger, usually considered about eighteen English inches. The geometrical cubit of Vitruvius was equal to six ordinary cubits.

**CUL DE FOUR.** (Fr.) A low vault spherically formed on a circular or oval plan. An oven-shaped vault.

**CULMEN.** In ancient Roman architecture, the ridge-piece of the roof.

**CULVERT.** An arched channel of masonry or brickwork built beneath the bed of a canal for the purpose of conducting water under it. If the water to be conveyed has nearly the same level as the canal, the culvert is built in the form of an inverted siphon, and acts on the principle of a water-pipe. The word also signifies any arched channel for water under ground.

**CULVER-TAIL.** The same as DOVE-TAIL, which see.

**CUNÆUS.** (Lat.) That part of the Roman theatre where the spectators sat.

**CUPOLA.** (It. from *Cupo*, hollow.) A term, properly speaking, which is confined to the *underside* or ceiling part of a dome. See DOME.

**CUPBOARD.** A recess in a wall, fitted with shelves as a receptacle for articles of the tea table.

**CURB ROOF.** One formed of four contiguous planes externally inclined to each other, the ridge being in the line of concourse of the two middle planes and the highest of the three lines of concourse. A roof of this construction (see 2035.) is frequently termed a *Mansard roof*, from the name of its inventor. Its principal advantage over other roofing arises from its giving more space in the garrets.

**CURB FOR BRICK STEPS.** A timber nosing, generally of oak, used not only to prevent the steps from wearing, but also from being dislocated or put out of their places. When the steps are made to return, the curb also returns, but when they profile against a wall, the ends of the curb or nosing pieces house at each end into the wall.

**CURB PLATE.** A circular continued plate, either scarfed together or made in two or more thicknesses. The wall plate of a circularly or elliptically ribbed dome is called a *curb-plate*, as likewise the horizontal rib at the top, on which the vertical ribs terminate. The plate of a skylight, or a circular frame for a well, is also called a curb-plate. The name is moreover given to a piece of timber supported in a curb roof by the upper ends of the lower rafters for receiving the feet of the upper rafters, which are thence called *curb-rafters*.

**CURB-STONES.** Those in the foot-paving of a street which divide it from the carriage-paving, above which they are or ought to be raised.

**CURIA.** (Gr.) A Roman council-house. The city and empire contained many curiæ.

- The *curia municipalis*, or *domus curialis*, seems to have, in destination, resembled our Guildhall. The *curia dominicalis* was a sort of manor house.
- CURLING STUFF.** That which is affected from the winding or coiling of the fibres round the boughs of the tree where they begin to shoot out of the trunk. The double iron plane is the best for working it.
- CURRENT.** The necessary slope of a piece of ground or pavement for carrying off the water from its surface.
- CURSOR.** (Lat.) The point of a beam compass that slides backwards and forwards. Also the part of a proportional compass by which the points are set to any given ratio.
- CURTAIN STEP.** The first or bottom step by which stairs are ascended, ending at the furthest point from the wall, in which it is placed in a scroll; perhaps taking its name from the step curling round like a cur's tail.
- CURVATURE.** See RADIUS OF CURVATURE.
- CURVE.** (Lat. *Curvus*.) A line that may be cut by a straight line in more points than one.
- CURVILINEAR.** Bounded by curve lines; thus a curvilinear roof is one erected on a curved plan, circular, elliptical, or otherwise.
- CUSHION RAFTER.** See PRINCIPAL BRACE.
- CUSP.** (Lat. *Cuspis*.) One of the pendants of a pointed arch, or of the arched head of a compartment of such an arch, or one of the several pendants forming what may be termed a *polyfoil*. Two cusps form a trefoil, three a quatrefoil, and so on.
- CUSTOM HOUSE.** See Book III. Chap. III. Sect. 15. An edifice erected for the receipt of the customs' duties payable on the importation and exportation of merchandise.
- CUT.** In inland navigation, the same as canal, arm, or branch.
- CUT BRACKETS.** Those moulded on the edge.
- CUT ROOF.** One that is truncated.
- CUT STANDARDS.** For shelves, the upright pieces supporting shelves above a dresser when cut into mouldings.
- CUT STONE.** Hewn stone, or that which is brought into shape by the mallet and chisel.
- CUTTING PLANE.** A plane dividing or cutting a solid into two parts in any direction.
- CYCLOGRAPH.** (Gr. *Κυκλος* and *Γραφω*.) In practical geometry, an instrument for describing the arc of a circle to any chord and versed sine, but chiefly used in flat segments, or those whose curvatures approach to straight lines.
- CYCLOID.** (Gr. *Κυκλοειδης*.) A figure described by rolling a circle upon a plane along a straight edge, until the point on the circle which touches the straight edge return again to it after a revolution. The point traces the curve called the *cycloid* or *trochoid*.
- CYCLOPEAN BUILDINGS.** See Book I. Chap. II. Sect. 2.
- CYLINDER.** (G. *Κυλινδρον*.) A solid whose base is a circle, and whose curved surface is every where at an equal distance from the axis or line supposed to pass through its middle. Its formation may be conceived to be generated by the revolution of a rectangular parallelogram about one of its sides. The cone, sphere, and cylinder have a remarkable relation to each other, first discovered by Archimedes, namely, that the cone is one third the cylinder having the same base and altitude; and the inscribed sphere two thirds of the cylinder; or the cone, sphere, and cylinder are to each other as the numbers 1, 2, 3. It is termed a *right cylinder* when the axis is at right angles to the base, but if at an oblique angle the cylinder is said to be oblique.
- CYLINDRICAL CEILING OR VAULTING.** Vulgarly called a *waggon-headed ceiling*. One in the shape of the segment of a cylinder. The cylindrical ceiling appears to have been first used by the Romans. It admits of being pierced by *lunettes* for the admission of light, which form cylindro-cylindric arches, and is usually formed into panels or coffers. See p. 774.
- CYLINDRICAL WORK.** Any kind of work which partakes of the shape of a cylinder, of whatever material it be formed.
- CYLINDROID.** A solid which differs from a cylinder in having ellipses instead of circles for its ends or bases.
- CYMA.** (Gr. *Κυμα*, a wave.) A moulding taking its name from its contour resembling that of a wave, being hollow in its upper part and swelling below. Of this moulding there are two sorts, the *cyma recta* thus, just described, and the *cyma reversa* thus, wherein the upper part swells, whilst the lower is hollow. By the workmen these are called *ogees*.
- CYMATIUM.** (Gr.) The upper moulding of a cornice.
- CYMEA.** The same as FILLET, which see.
- CYPRESS.** (Lat. *Cupressus*.) The wood of the cypress was valued for its hardness and durability by the ancient architects.
- CYRIADES.** See ARCHITECTS, list of, 54.
- CYRUS.** See ARCHITECTS, list of, 36.
- CYZICENUS.** In ancient architecture, a large hall decorated with sculpture.

## D.

**DADO.** The die or part in the middle of the pedestal of a column between the base and cornice. It is of a cubic form, whence the name of die. The term is also applied to that part of an apartment between the plinth and impost moulding.

**DAIRY.** An apartment in a house, or a separate building, for the preservation of milk, and the manufacture of it into butter, cheese, or other dairy produce. When on a small scale, where the milk is only used for butter, the dairy may be a room on the north side of the dwelling, or form one of the offices connected with the kitchen court. The temperature of a dairy should be within the range of forty-eight to fifty-five degrees of Fahrenheit, with sufficient ventilation to discharge all smells and impurities of the air. A dairy on a large scale should be a detached building, in which case it should contain a milk-room, a churning-room, and a dairy scullery, or place for scalding the utensils. If cheese be to be made, a room is required for the cheese-press, and another for drying the cheeses.

**DAIS. (Fr.)** The platform or raised floor at the upper end of a dining-hall, where the high table stood; also the seat with a canopy open for it, for those guests who sat at the high table.

**DAM.** Architecturally, a fence against water. See **COFFER-DAM**.

**DAMPNESS.** A moisture generally attendant on buildings finished hastily, on account of the materials, not being dry, carrying up the moisture by capillary attraction. A layer of powdered charcoal mixed with pitch or resin and powdered pitcoal laid over one of the courses of the wall near the foundations will prevent the evil.

**DANCE.** See **ARCHITECTS**, list of, 290.

**DANCE, GEORGE.** See **ARCHITECTS**, list of, 314.

**DAYS or BAYS.** In Gothic architecture, the compartments in windows formed by the transoms or horizontal pieces and mullions or vertical pieces.

**DEAD SHORE.** A piece of timber worked up in brickwork to support a superincumbent mass until the brickwork which is to carry it has set or become hard.

**DEAFENING SOUND-BOARDING.** The *pugging* used to prevent the passage of sound through wooden partitions.

**DEAL.** (Sax. *Delan*, to divide.) Properly the small thickness of timber into which a piece of any sort is cut up; but the term is now, though improperly, restricted in its signification to the wood of the fir tree cut up into thicknesses in the countries whence deals are imported, viz. Christiana, Dantzic, &c. Their usual thickness is three inches, and their width nine. They are purchased by the hundred, which contains 120 deals, be their thickness what it may, reduced by calculation to a standard thickness of one inch and a half and to a length of twelve feet. *Whole deal* is that which is one inch and a quarter thick, and *slit deal* is half that thickness. See **BOARD**.

**DECAGON.** (Gr. *Δεκα*, ten, and *γωνία*, an angle.) A geometrical figure having ten sides and ten angles. If the sides and angles are all equal, the figure is a regular decagon, and capable of being inscribed in a circle.

**DECASTYLE.** See **COLONADE**.

**DECIMAL. (Lat.)** A term applied to a system of arithmetic in which the scale of numbers proceeds by tens.

**DECORATION.** The combination of ornamental objects which the desire for varying a form or forms brings together in many ways for embellishing those subjects which are the objects of art. See **Book III. Chap. I. Sect. 1.**

**DELIQUÆ. (Lat.)** A term used by Vitruvius to designate the rafters which formed the ridge of the roof and threw the water on each side.

**DEMETRIUS.** See **ARCHITECTS**, list of, 4.

**DENSITY. (Lat. Densus, thick.)** A term used in physics to denote the quantity of matter which a body contains under a given or determinate surface; for example, a cubic foot. The quantity of matter in a body is called its mass, and is measured by the weight of the body, to which it is always proportional; hence the density of a body is great in proportion as its weight is great, and its volume small; or the density of bodies is directly as their masses, and inversely as their volumes.

**DENTILS or DENTELS. (Lat. Dentes, teeth.)** The small square blocks or projections in the bed mouldings of cornices in the Ionic, Corinthian, Composite, and occasionally Doric orders; their breadth should be half their height; and, as Vitruvius teaches, the intervals between them two thirds of their breadth. In the Grecian orders they are not used under modillions.

**DESCRIPTION OF A BUILDING.** The same as **SPECIFICATION**. See **Book II. Chap. III. Sect. 13.**

**DESCRIPTIVE GEOMETRY.** That which consists in the application of geometrical rules to the representation of the figures, and the various relations of the forms of bodies, according to certain conventional forms. It differs from perspective, on account of the repre-

- sensation being made in such a manner that the exact distance between the different points of the body represented can always be found, and consequently all the mathematical relations resulting from the form and position of the body may be deduced from the representation. See Book II. Chap. I. Sect. 6.
- DESIGN.** (Lat. *Designo*.) The idea formed in the mind of an artist on any particular subject, which he transfers by some medium, for the purpose of making it known to others. Every work of design is to be considered either in relation to the art that produced it, to the nature of its adaptation to the end sought, or to the nature of the end it is destined to serve; hence its beauty is dependent on the wisdom or excellence displayed in the design, on the fitness or propriety of the adaptation, and upon the utility for the end. The considerations of design, fitness, and utility will be seen at large in Book III. Chap. I. Sects. 1, 2.
- DESTEMPER.** See **DISTEMPER**.
- DETAILS.** A term usually applied to the drawings on a larger scale for the use of builders, and generally called *working drawings*. See Book II. Chap. IV. Sect. 4.
- DETERMINING LINE.** In the conic sections, a line parallel to the base of the cone; in the hyperbola this line is within the base; in the parabolic sections it forms a tangent to the base, in the elliptic it falls without it. In the intersecting line of a circle, the determining line will never meet the plan of the base to which it is parallel.
- DETRIANUS.** See **ARCHITECTS**, list of, 49.
- DEXIPHANES.** See **ARCHITECTS**, list of, 35.
- DIACONICON.** A place contiguous to the ancient churches, wherein were preserved the sacred vestments, vessels, relics, and ornaments of the altar. In modern language, the sacristy.
- DIAGONAL.** (Gr. *Δια*, through, and *γωνία*, angle.) A straight line drawn through a figure joining two opposite angles. The term, in geometry, is used in speaking of four-sided figures, but it is nevertheless properly applied with reference to all polygons whereof the number of sides is not less than four. The term diameter is used by Euclid in the same sense; but modern geometers use the term diameter only in speaking of curve lines, and diagonal when speaking of angular figures.
- DIAGONAL SCALE.** A compound scale formed by vertical and horizontal subdivisions with diagonals drawn across them, whereby we are enabled to measure off very small parts by means of equidistant parallels crossing others of the same kind.
- DIAGRAM.** (Gr. *Διαγραμμα*, from *Δια*, through, and *γραφω*, I write.) The figure or scheme for the illustration of a mathematical or other proposition.
- DIAGRAPH.** (Gr.) A recently invented French instrument for drawing objects from nature.
- DIAMETER.** (Gr. *Δια*, through, and *Μετρον*, a measure.) A straight line passing through the centre of a geometrical figure, as that of a circle, ellipse, or hyperbola. The term is architecturally used to express the measure across the lower part of the shaft of a column, and is usually divided into sixty parts, called minutes, which form the scale for the measurement of all the parts of an order.
- DIAMOND PAVEMENT.** One disposed in squares arranged diagonally.
- DIASTYLE.** (Gr. *Δια* and *Στυλος*, a column.) That distance between columns which consists of three diameters, or, according to some, of four diameters. The term is sometimes used adjectively, to signify that the building is arranged with those intervals between the columns.
- DIATONI.** (Gr. *Δια* and *Τονος*, an extension.) In ancient architecture the angle stones of a wall, wrought on two faces, and which, from stretching beyond the stones above and below them, made a good bond or tie to the work.
- DIAZOMA.** (Gr. *Δια*, through, and *Ζωμα*, a cincture.) In ancient architecture, the landings or resting places which, at different heights, encircled the amphitheatre like so many bands or cinctures, whence the name.
- DICASTERIUM.** (Gr. *Δικη*, justice.) In ancient architecture, the name of a tribunal or hall of justice.
- DICTYOTHETON.** (Gr. *Δικτυον*, a net, and *Τιθημι*, I place.) In ancient architecture, masonry worked in courses, like the meshes of a net. Also open lattice work, for admitting light and air.
- DIDORON.** See **BRICK**.
- DIE OF A PEDESTAL.** That part included between the base and the cornice.
- DIGGING.** In soft ground, one man with a spade will throw up, per hour, a cubic yard of twenty-seven feet. If a mattock must be used, the same quantity will require two men, and in a strong gravel, three. It will require three men to wheel thirty cubic yards of gravel in a day to the distance of twenty yards.
- DIGLYPH.** (Gr. *Δις*, twice, and *Γλυφω*, I carve.) A projecting face, with two panels or channels sunk thereon.

- DILAPIDATION.** The state of decay and ruin into which a building has been permitted to fall.
- DIMENSION.** (Lat. *Dimetior*.) In geometry is either length, breadth, or thickness. Thus a line has one dimension, as of length; a superficies has two, length and breadth; a solid has three dimensions, length, breadth, and thickness.
- DIMINISHED ARCHES.** Those lower or less than a semicircle, called by the French *routes surbaissées*.
- DIMINISHED BAR OF A SASH.** One thinner on the edge towards the room than on that towards the glass of the window.
- DIMINISHED COLUMN.** A column whereof the upper diameter is less than the lower.
- DIMINISHING RULE.** A board cut with a concave edge, so as to ascertain the swell of a column, and to try its curvature.
- DIMINISHING SCALE.** A scale of gradation used in finding the different points for drawing the spiral curve of the Ionic volute, by describing the arc of a circle through every three preceding points, the extreme point of the last arc being one of the next three. Each point through which the curve passes is regulated so as to be in a line drawn to the centre of the volute, and the lines at equal angles with each other.
- DIMINUTION OF A COLUMN.** The continued contraction of the diameter of the column as it rises. Most of the modern authors make the diminution to commence from one third of the height of the column; but in all the ancient examples the diminution commences from the bottom of the shaft. See *ENTASIS*. In Gothic architecture neither swell nor diminution is used, all the horizontal sections being similar and equal.
- DINING OR DINNER ROOM.** Generally one of the largest rooms in a dwelling-house. In large buildings it extends to forty or fifty feet in length, and the breadth is from half to three fourths the length. In middle-sized houses, dining-rooms run from twenty-four down to eighteen feet in length by eighteen to sixteen feet in width, and thirteen or fourteen feet in height. In houses, the largest room on the ground-floor should be appropriated to the purpose.
- DINOCRATES.** See *ARCHITECTS*, list of, 22.
- DIOTI SALVI.** See *ARCHITECTS*, list of, 94.
- DIPYTERAL.** (Gr. *Διπτερος*, double-winged.) In ancient architecture, a temple having a double range of columns on each of its flanks. See *TEMPLE*.
- DIRECT RADIAL.** In perspective, a right line from the eye perpendicular to the picture.
- DIRECTING LINE.** In perspective, the line in which an original plane would cut the directing plane.
- DIRECTING PLANE.** In perspective, a plane passing through the point of sight, or the eye, parallel to the picture.
- DIRECTING POINT.** In perspective, that in which any original line produced cuts the directing plane.
- DIRECTOR OF AN ORIGINAL LINE.** In perspective, the straight line passing through the directing point and the eye of a spectator.
- DIRECTOR OF THE EYE.** The intersection of the plane with the directing plane perpendicular to the original plane and that of the picture, and hence also perpendicular to the directing and vanishing planes, since each of the two latter is parallel to each of the two former.
- DIRECTRIX.** In geometry the name given to a certain straight line perpendicular to the axes of a conic section. One of the properties of these curves is that the distance of any point of the curve from the directrix is to the distance of the same point from the focus in a constant ratio. The name is sometimes applied generally to any straight or curved line required for the description of any curve.
- DISCHARGE.** (Fr. *Décharger*.) The relief given to a beam, or any other piece of timber, too much loaded by an incumbent weight of building. When the relief is given, the weight is said to be discharged.
- DISCHARGING ARCHES.** Those built over wooden lintels, whereby the bearing upon them is taken off. The chords of discharging arches are not much longer than the lintel, being the segments of very large circles. A temporary arch is frequently introduced, and removed on completing the building. Sometimes the arches are built without any lintel under them.
- DISHING OUT.** The same as *CRADLING*, which see.
- DISPLUVIATUM.** (Lat.) In ancient architecture, a place from which the rain is conveyed away in two channels. According to Vitruvius, a *cavadium displuviatum* was an open court exposed to the rain.
- DISPOSITION.** (Lat.) One of the essentials of architecture. It is the arrangement of the whole design by means of ichnography (plan), orthography (section and elevation), and scenography (perspective view). It differs from distribution, which signifies the particular arrangements of the internal parts of a building.

- DISTANCE OF THE EYE.** In perspective, the distance of the eye from the picture in a line perpendicular to the plan thereof.
- DISTANCE, POINT OF.** In perspective, the distance of the picture transferred upon the vanishing line from the centre, or from the point where the principal ray meets it; and thus it is generally understood to be on the vanishing line of the horizon.
- DISTANCE OF A VANISHING LINE.** The length of a perpendicular falling from the eye perpendicular to the vanishing plane.
- DISTEMPER.** (Fr. Detemper.) In painting, a preparation of opaque colour, ground up with size and water.
- DISTRIBUTION.** (Lat.) The arrangement of the various apartments of a building.
- DITRIGLYPH.** (Gr. Δις, twice, Τρεῖς, three, and Γλυφω, I carve.) An arrangement of intercolumniations in the Doric order, by which two triglyphs are obtained in the frieze between the triglyphs that stand over the columns.
- DODECAGON.** (Gr. Δωδεκα and Γωνία, an angle.) A regular polygon of twelve equal sides.
- DODECAHEDRON.** (Gr. Δωδεκα and Ἔδρα, a seat.) One of the five platonic bodies, or regular solids, its surface being composed of twelve equal and regular pentagons.
- DOG-LEGGED STAIRS.** Such as are solid between the upper flights, or such as have no well-hole, and in which the rail and balusters of both progressive and retrogressive flight fall in the same vertical plane. The steps are fixed to strings, newels, and carriages; and the ends of the steps in the inferior kind only terminate on the side of the string without any housing.
- DOME.** (Lat. Domus.) The spherical, or other figure, convex roof over a circular or polygonal building. A *surbased* or *diminished dome* is one that is segmental on its vertical section, a *surmounted dome* is one that is higher than the radius of its base. There is great variety in the forms of domes, both in plan and section. In the former, they are circular and polygonal; in the latter, we find them semicircular, semi-elliptical, segmental, pointed, sometimes in curves of contrary flexure, bell-shaped, &c. The oldest dome on record is that of the Pantheon at Rome, which was erected under Augustus, and is still perfect. Below is a list of the principal domes in Europe, with their dimensions; the heights in the third column are from the ground: —

Place.	Feet Diam.	Feet High.
Pantheon at Rome - - - - -	142	143
Duomo, or Sta. Maria del Fiore, at Florence -	139	310
St. Peter's at Rome - - - - -	139	330
Sta. Sophia at Constantinople - - - - -	115	201
Baths of Caracalla (ancient) - - - - -	112	116
St. Paul's, London - - - - -	112	215
Mosque of Achmet - - - - -	92	120
Chapel of the Medici - - - - -	91	199
Baptistery at Florence - - - - -	86	110
Church of the Invalids at Paris - - - - -	80	173
Minerva Medica at Rome - - - - -	78	97
Madonna della Salute, Venice - - - - -	70	133
St. Génévieve at Paris (Pantheon) - - - - -	67	190
Duomo at Siena - - - - -	57	148
Duomo at Milan - - - - -	57	254
St. Vitalis at Ravenna - - - - -	55	94
Val de Grace at Paris - - - - -	55	183
San Marco, Venice - - - - -	44	

- DONJON.** (Fr.) The massive tower within ancient castles to which the garrison might retreat in case of necessity. It was centrally placed, and frequently raised on an artificial elevation.
- DOOKS.** The same as **WOODEN BRICKS**, which see. It is a Scotch term.
- DOOR.** (Sax. Dop, Gr. Θύρα.) The gate or entrance of a house or other building, or of an apartment in a house. It must be proportioned to the situation and use for which it is intended. Thus, for an ordinary dwelling-house, a door should not be less than seven to eight feet high, and three to four feet broad; but to churches and public buildings the entrance-doors should be much wider, to allow of a multitude to pass out. So in stately mansions, the doors must be from six to twelve feet in width, and of proportionate height. For the different sorts and profiles of doors, see Book III. Chap. I. Sect. 19.; for joinery of doors, Book II. Chap. III. Sect. 5.
- DOOR FRAME OF CASE.** The wooden frame enclosing a door.
- DORIC ORDER.** See Book III. Chap. I. Sect. 4., and Book I. Chap. II. Sect. 4.

- DORMANT TREE OF SUMMER.** The lintel of a door, window beam, &c. A beam tenoned into a girder to support the ends of joists on both sides of it. *Summer*, in some parts, is the common term for a girder.
- DORMER.** A window placed on the inclined plane of the roof of a house, the frame being placed vertically on the rafters.
- DORMITORY.** (Lat. *Dormio*, I sleep.) A large sleeping-room, capable of containing many beds.
- DORON.** See **BRICK**.
- DOVE-HOUSE, or DOVE-COT.** A building for keeping tame pigeons, the only essential difference between which and a common poultry house is, that the entrance for the birds must be placed at a considerable height from the ground, because of the flight of pigeons being so much higher than other birds.
- DOVE-TAIL** (from its spreading like a pigeon's tail). A joint used by carpenters and joiners in connecting two pieces of wood, by letting one into the other, in the form of the expanded tail of a dove. It is the strongest method of joining masses, because the tenon or piece of wood widens as it extends, so that it cannot be drawn out, because the tongue is larger than the cavity through which it would have to be drawn. The French call this method *queue d'hironde*, or swallow's tail.
- DOUBLE CURVATURE.** The curvature of a curve, whereof no part can be brought into a plane, such as the cylindro-cylindric curve, &c.
- DOUBLE FLOOR.** One constructed of binding and bridging joists. See p. 541.
- DOUBLE-HUNG SASHES.** See p. 572, 573.
- DOUBLE VAULTS.** Two vaults of brick or stone carried up separately with a cavity between them.
- DOUBLING.** A term used in Scotland to denote eaves' boards.
- DOUCINE.** The French term for the cyma recta.
- DOWELS.** Pins of wood or iron used at the edges of boards in laying floors, to avoid the appearance of the nails on the surface. Floors thus laid are called *dowelled floors*.
- DRAG.** (Verb.) A term applied to anything bearing down or rubbing on another. Thus, a door is said to drag when its hinges become so loosened that the lower edge rubs upon the floor.
- DRAGON BEAM or PIECE.** In carpentry, a short beam or piece of timber, lying diagonally with the wall-plates at the angles of a roof for receiving the heel or foot of the hip rafter. It is fixed at right angles with another piece, called the *angle tie*, which is supported by each returning wall-plate, on which it is cocked down.
- DRAIN.** A subterraneous or other channel for waste water. See Book II. Chap. III. Sect. 1.
- DRAUGHT.** The representation of a building on paper, explanatory of the various parts of the interior and exterior, by means of plans, elevations, and sections, drawn to a scale, by which all the parts are exhibited in the same proportion as the parts of the edifice intended to be represented.
- DRAUGHT.** In masonry, a part of the surface of the stone, hewn to the breadth of the chisel on the margin of the stone according to the curved or straight line to which the surface is to be brought. When the draughts are framed round the different sides of the stone, the intermediate part is wrought to the surface by applying a straight edge or templet. In very large stones, when the substance needs much reduction, it is usual to make several intermediate parallel *draughts*, and thus the intermediate parts may be hewn down nearly by the eye, without much application of the straight edge or templet.
- DRAUGHT COMPASSES.** Those with moveable points.
- DRAW BORE.** (Verb.) The pinning a mortise and tenon, by piercing the hole through the tenon nearer to the shoulder than the holes through the cheeks from the abutment in which the shoulder is to come in contact.
- DRAW BORE PINS.** Pieces of steel in the shape of the frustrum of a cone, rather taper, and inserted in handles with the greatest diameter next to the handle, for driving through the draw bores of a mortise and tenon in order to bring the shoulder of the rail close home to the abutment on the edge of the style. When this is effected, the draw bore pins, when more than one are used, are taken out singly, and the holes immediately filled up with wooden pegs.
- DRAWBRIDGE.** One made with long and heavy levers to raise or let it down at pleasure.
- DRAWING.** See Book II. Chap. IV. Sect. 1.
- Drawing is the art of representing any object by means of lines circumscribing its boundaries. For working drawings see Book II. Chap. IV. Sect. 1.
- DRAWINGS NECESSARY IN COMPOSITIONS.** Book III. Chap. II. Sect. 2.
- DRAWING ROOM,** perhaps more properly **WITHDRAWING ROOM.** The apartment to which the company *withdraw* after dinner.
- DRESSED.** A term in masonry which expresses the operation a stone has undergone before

building it in the wall, whether by the hammer only or by the mallet and chisel, and then rubbing the face smooth. In Scotland the term is used to signify hammer dressing only.

**DRESSER.** A table placed against a wall in a kitchen, usually with drawers, and having shelves over it.

**DRESSING ROOM.** A room generally adjoining to and communicating with the sleeping room, used, as the name implies, for dressing in. It should have a separate door to open on the lobby or passage of communication.

**DRESSINGS.** All kinds of mouldings beyond the naked walls or ceilings are called by the general name of dressings. In joinery it is a term applied to the architraves or other appendages of apertures.

**DRIFT.** (Sax. *Druifan*.) The horizontal force which an arch exerts with a tendency to upset the piers from which it springs.

**DRIP.** See **CORONA**.

**DRIPPING EAVES.** (Dan. *Dripper*, to drop.) The lower edges of a roof wherefrom the rain drips or drops to the ground. By the Building Act dripping eaves are prohibited within the bills of mortality, towards any street or public way.

**DROPS.** (Sax. *Droppan*.) The frusta of cones in the Doric order, used under the triglyphs in the architrave below the *tænia*. They are also employed in the under part of the mutuli or modillions of the order. In the Greek examples they are sometimes curved a little inwards on the profile.

**DROVED ASHLAR.** A term used in Scotland for chiselled or random tooled ashlar. It is the most inferior kind of hewn work in building. What is in that country called broached work is sometimes done without being droved; but in good broached work the face of the stone should be previously droved, and then broached.

**DROVED AND BROACHED.** A term used in Scotland to signify work that has been roughed and then tooled clean.

**DROVED AND STRIPED.** Work that is first droved and then striped. The stripes are shallow grooves done with a half or three-quarter inch chisel, about an eighth of an inch deep, having the droved interstices prominent. This and the two preceding sorts of work are not much used in the southern part of England.

**DRUELL.** See **ARCHITECTS**, list of, 166.\*

**DRUIDICAL ARCHITECTURE.** See Book I. Chap. II. Sect. 1.

**DRUM.** (Dan. *Tromme*.) The upright part under or above a cupola. The same term is sometimes applied to the solid part or vase of the Corinthian and Composite capitals.

**DRY ROT.** A disease of timber which destroys the cohesion of its parts; it is usually ascribed to the attacks of fungi, such as the *Polyporus destructor* and *Merulius lacrymans*, whose spawn appears upon the surface overspreading it like a tough thick skin of white leather; and there is no doubt of its being often connected with the appearance of such fungi. Dry rot is, however, in some cases to be identified with the presence of fungi of a more simple kind than those just mentioned, such as those of the genus *Sporotrichum*. See p. 490.

**DUBBING OUT.** A term used by plasterers to signify the bringing of an uneven surface to a plane by pieces of tile, slate, plaster, or the like.

**DUNSTAN.** See **ARCHITECTS**, list of, 75.

**DUODECIMAL.** (Lat. *Duodecim*.) Proceeding by twelves. It is a term applied to an operation in arithmetic, which is explained in p. 296, *et seq.*

**DWANG.** A term used in Scotland to denote the short pieces of timber employed in strutting a floor.

**DWARF WAINSCOTING.** Such as does not reach the whole height of a room, being usually four, five, or six feet high.

**DWARF WALLS.** Low walls of less height than the story of a building; sometimes the joists of a ground floor rest upon dwarf walls. The enclosures of courts are frequently formed by them with a railing of iron on the top; and indeed any low wall used as a fence is a dwarf wall.

**DWELLING HOUSE.** See p. 810, *et seq.*

**DWELLINGS, DIFFERENT EARLY SORTS OF.** See Book I. Chap. I. Sect. 3.

**DYE.** See **DIE**.

**DYNAMICS.** (Gr. *Δυναμις*, force or power.) As generally understood, the science which treats on the motion of bodies, because it is only known to us by the motion it produces in the body on which it acts. It is however usually restricted to those circumstances of motion in which the moving bodies are at liberty to obey the impulses communicated to them; the opposite cases, or those in which the bodies, whether by external circumstances or by their connection with one another, are not at liberty to obey the impulses given, being within the science of mechanics.

## E.

- EAGLE.** (Gr. Αἰετος.) A term used by the Greeks for the frontispiece or pediment of their temples.
- EARS.** The same as CROSETTES, which see.
- EARNULPH.** See ARCHITECTS, list of, 89.
- EAURALD.** See ARCHITECTS, list of, 70.
- EAVES.** (Probably Fr. Eaux.) The lowest edges of the inclined sides of a roof which project beyond the face of the walls, so as to throw the water off therefrom, that being their office.
- EAVES' BOARD, EAVES' LATH, EAVES' CATCH.** See ARRIS FILLET.
- EBONY.** The wood of a natural order of shrubby or arborescent exogens, chiefly inhabiting the tropics. Some species are remarkable for the hardness and blackness of their wood, which is principally used for furniture.
- ECCENTRICITY.** The difference of centre from another circle. The distance between the foci of an ellipse.
- ECHÆA.** (Gr. Ἠχώ, I sound.) In ancient architecture, sonorous vessels of metal or earth, in the form of a bell, used in the construction of theatres for the purpose of reverberating the sound of the performer's voice. They were distributed between the seats, and are described in the fifth book of Vitruvius, who states that Mummius introduced them in Rome, after the taking of Corinth, where he found this expedient used in the theatre.
- ECHINUS.** (Gr. Ἐχινος.) The same as the ovolo or quarter round, though the moulding is only properly so called when carved with eggs and anchors. (See ANCHOR.) It is the shell or husk of the chestnut, though the ornament does not seem to bear much resemblance to it.
- ECPHORA.** (Gr. Ἐκ, out, Φέρω, I bear.) A word used by Vitruvius (lib. iii. cap. 3.) to signify the proecture of a member or moulding of a column, that is, the distance of its extremity from the naked of the column, or, according to others, from the axis.
- ECTYPE.** (Gr. Ἐκτύπος.) An object in relieve, or embossed.
- EDGE.** (Sax. Ēge.) The intersection of two planes or surfaces of a solid, which therefore is either straight or curved according to the direction of the surfaces. See ARRIS. It is also that side of a rectangular prismatic body which contains the length and thickness; but in this sense of the term, the body to which it applies is generally understood to be very thin; thus we say "the edge of a door," "the edge of a board," meaning the narrow side. The edge of a tool is the meeting of the surfaces when ground to a very acute angle.
- EDGE TOOLS** are those which clip or shave in the operation of working.
- EDGING.** In carpentry, the reducing of the edges of ribs or rafters, whether externally or internally, so as to range in a plane or in any curved surface required. *Backing* is a particular use of edging, and only applies to the outer edges of ribs or rafters; but edging or ranging is a general term, and applies either to the backing or internal surface. See BACKING.
- EDIFICE.** (Lat. Œdificium.) A word synonymous with fabric, building, erection; the word is, however, more usually employed to denote architectural erections distinguished for grandeur, dignity, and importance.
- ΕΔΝΟΘΗ.** See ARCHITECTS, list of, 74.
- EFFECT.** (Lat. Efficacio.) That quality in works of art whose nature is to give particular efficacy to other qualities, so as to bring them out and attract the eye of the spectator.
- EGBERT.** See ARCHITECTS, list of, 68.
- EGG AND TONGUE.** Ornaments used in the echinus, supposed by Quatremère de Quincy to have had their origin in the head of Isis, and, as he imagines, representing a mystical collar or necklace of the mundane egg and the tongue of the serpent of immortality; but as we think, in the representation of much more simple objects, those of nature herself. See ECHINUS.
- EGYPTIAN ARCHITECTURE.** See Book I. Chap. II. Sect. 7.
- EGYPTIAN HALL.** See CECUS.
- ΕΛΜΟΘΗΣΙΟΝ.** (Gr. Ελαιοον, oil.) In ancient architecture, an apartment in the baths wherein, after leaving the bath, the bathers anointed themselves.
- ELASTIC CURVE.** In mechanics, the figure assumed by an elastic body, one end whereof is fixed horizontally in a vertical plane, and the other loaded with a weight which, by its gravity, tends to bend it.
- ELASTICITY.** (Gr. Ελαστική, a spring, from Ελαυνω, I draw.) In physics that property possessed by certain bodies of recovering their form and dimensions after the external force which has dilated or compressed them is withdrawn. It is only perfect when the body recovers exactly its primitive form after the force to which it has been subjected has been removed, and that in the same time as was required for the force to produce the alteration. This is however a quality not strictly found in nature.

- ELBOWS.** (Sax. *Elboga*.) The upright sides which flank any pannelled work, as in windows below the shutters, &c.
- ELEVATION.** (Lat. *Elevatio*.) A geometrical projection drawn on a plane perpendicular to the horizon.
- ELLIPSE or ELLIPSIS.** (Gr. *Ελλειψις*, defect.) One of the conic sections produced by cutting a cone entirely through the curved surface, neither parallel to the base; nor making a subcontrary section, so that the ellipsis, like the circle, is a curve that returns into itself and completely encloses a space.
- ELLIPSOGRAPH.** An instrument for describing an ellipsis by continued motion.
- ELLIPSOID.** See **CONOID**.
- ELLIPTIC ARCH.** A portion of the curve of an ellipsis employed as an arch.
- ELLIPTIC COMPASSES.** The same as **ELLIPSOGRAPH**.
- ELLIPTIC WINDING STAIRS.** Such as are cased in and wind round an elliptic newel.
- ELM.** (Lat. *Ulmus*.) A forest tree occasionally used in building. See **Book II. Chap. II. Sect. 4.**
- ELPHAGE.** See **ARCHITECTS**, list of, 77.
- EMBANKMENT.** A term signifying any large mound of earth on the sides of a passage for water or other purposes; also for protection against the action of the sea. It is usually constructed of earth, and, when necessary to resist much force, cased with brick or stone.
- EMBATTLED.** A wall indented with notches in the form of embrasures on the top of a wall, parapet, or other building. It is sometimes called *crenelle*.
- EMBATTLED ARONADE.** See **ARONADE**.
- EMBATTLED-BATTLED LINE.** A straight line bent into right angles, so that if there be three sets of parts one set may be parallel to those of the other two.
- EMBATTLED BUILDINGS.** Those with embrasures in the parapets, resembling a castle or fortified place.
- EMBOSSING or EMBOSSED WORK.** (Fr. *Bosse*, a protuberance.) The raising or forming in relief any sort of figure, whether performed with the chisel or otherwise. It is a kind of sculpture, in which the figures rise from the plane on which they are formed, and as they are more or less prominent they are said to be in *alto*, *mezzo*, or *basso relievo*.
- EMBRASURE.** An opening made in the wall or parapet of a fortified place. The term is also applied to an enlargement within of the sides of a window, in which sense it is the same as **SPLAY**, which see.
- EMERE, D'.** See **ARCHITECTS**, list of, 232.
- EMPLECTON.** (Gr. *Εμπλεκω*, I entangle.) Among the ancients, a method of constructing walls, in which, according to Vitruvius, the front stones were wrought fair and the interior left rough and filled in with stones of various sizes.
- ENCARPUS.** (Gr. *Εν και κarpος*.) The festoons on a frieze, consisting of fruit, flowers, leaves, &c.
- END OF A STONE.** The two parallel sides which form the vertical joints.
- ENDECAGON.** (Gr. *Ενδεκα*, eleven, and *γωνια*, an angle.) A plain geometrical figure bounded by eleven sides.
- ENGAGED COLUMNS.** Those attached to walls, by which a portion of them is concealed. They never stand less than half their diameter out of the wall to which they are attached.
- ENGLISH BOND.** See p. 515.
- ENSEMBLE.** (Fr.) A term denoting the masses and details considered with relation to each other.
- ENTABLATURE.** (Fr. *Entablement*.) The whole of the parts of an order above a column. The assemblage is divided into three parts: the architrave, which rests immediately on the column; the frieze, next over the architrave, being the middle member; and the cornice, which is the uppermost part. The first and last are variously subdivided in the different orders. See the different orders, **Book III. Chap. I.**
- ENTASIS.** (Gr. *Εντασις*.) A delicate and almost imperceptible swelling of the shaft of a column, to be found in almost all the Grecian examples. It seems to have been adopted to prevent the crude appearance which the frusta of cones would have presented. This refinement is alluded to in the second chapter of the third book of Vitruvius, and was first in modern times observed in execution in 1814 by Mr. Allason.
- ENTER.** (Verb.) In carpentry and joinery, the act of inserting the end of a tenon in the mouth of a mortise previous to its being driven home to the shoulder.
- ENTRESOL.** (Fr.) A low story between two higher ones. See **MEZZANINE**.
- ENVELOPE.** (Verb.) The covering of a portion of the surface of a solid with a thin substance or wrapper, which in all points or parts comes in contact with the surface of such surface. To develop the surface of a solid is to find the envelopes that will cover its different parts.
- EPHEBEIUM.** (Gr.) A building, in ancient architecture, for the exercise and wrestling of the youth.

**EPICRANTIS.** (Gr.) A name given by the Greeks to the tiles forming the cyma or upper member of the cornice of their temples.

**EPICYCLOID.** (Gr. *Επικυκλος*, and *Ειδος*, form.) In geometry, a curve line generated by the revolution of a point in the circumference of a circle, which rolls on the circumference of another circle, either externally or internally.

**EPISCENIUM.** (Gr. *Επι*, upon, *Σκηνη*, a scene.) In ancient architecture, the upper order of the scene in a theatre.

**EPISTYLIUM.** Gr. *Επι*, upon, *Στυλος*, column.) The same as **ARCHITRAVE**, which see.

**EPITHEDES.** (Gr. *Επι*, upon, *Τιθημι*, I place.) The crown or upper mouldings of an entablature.

**EQUIANGULAR.** Having equal angles.

**EQUIDISTANT.** At equal distances.

**EQUILATERAL.** Having equal sides.

**EQUILIBRIUM.** In mechanics, an equality of forces in opposite directions, so as mutually to balance each other. For the arch of equilibrium see Book II. Chap. I. Sect. 9.

**ERGASTULUM.** In ancient architecture, a name given by the Romans to a prison or house of correction, where slaves, by the sole authority of their masters, were confined for their offences and subjected to hard labour. By the Greeks these buildings were called *sophonisteria*.

**ERWYN.** See **ARCHITECTS**, list of, 128.

**ESCOBEDO, D'.** See **ARCHITECTS**, list of, 197.

**ESGUERRA.** See **ARCHITECTS**, list of, 225.

**ESTIMATE.** (Substantive.) The computed cost of a building before the works are commenced. See Book II. Chap. III. Sect. 14.

**ESTRADE.** An even or level space; a public road.

**ETIENNE DE BONNEVEIL.** See **ARCHITECTS**, list of, 111.

**ETRUSCAN ARCHITECTURE.** See Book I. Chap. II. Sect. 12.

**EUDE DE MONTREUIL.** See **ARCHITECTS**, list of, 117.

**EUPALINUS.** See **ARCHITECTS**, list of, 5.

**EUPOLEMUS.** See **ARCHITECTS**, list of, 27.

**EURITHMY.** (Gr. *Ευρυθμια*, justness of proportion.) The regular, just, and symmetrical measures resulting from harmony in the proportions of a building or order. Vitruvius makes it one of his six essentials.

**EUSTACHIUS.** See **ARCHITECTS**, list of, 109.

**EUSTYLE.** (Gr. *Ευ*, well, and *Στυλος*, column.) See **COLONNADE**.

**EVAPORATION.** (Lat.) The conversion of substances into vapour, during which process a considerable quantity of sensible heat passes into the *latent* or insensible state. The circumstances which principally influence the process of evaporation, are extent of surface, and the state of the air in respect of temperature, dryness, stillness, and density.

**EVERSDEN, D'.** See **ARCHITECTS**, list of, 136.

**EVERSOLT.** See **ARCHITECTS**, list of, 103.

**EVOLUTE.** (Lat. *Evolvo*.) In the theory of curve lines, is a curve from which any given curve may be supposed to be formed by the *evolution* or unlapping of a thread from a surface having the same curvature as the first curve. The curve thus generated is called the *involute curve*.

**EXCAVATION.** (Lat.) As connected with architecture is the digging out or hollowing the ground for the foundations of a building, or of a floor below the level of the ground.

**EXCHANGE.** See Book III. Chap. III. Sect. 14.

**EXHEDRA.** (Gr. *Εξ*, out of, and *Εδρα*, a chair.) In ancient architecture, a small room in the baths and other buildings appropriated for conversations.

**EXOSTRA.** (Gr.) In ancient architecture, a machine for representing the interior part of a building as connected with the scene in a theatre.

**EXPANSION.** One of the ordinary effects of heat, which enlarges the bulk of all matter. Though the expansion of solids is by increase of temperature comparatively small, it may be rendered sensible by carefully measuring the dimensions of any substance when cold and again when heated. Thus an iron bar fitted to a gauge, showing its length and breadth, will, when heated, no longer pass through the apertures. The metals are most expansible by heat and cold. The following exhibits the change which some of them undergo when heated from the freezing to the boiling point of water:—

				Temperature.	
				32°	212°
Platinum	-	-	-	120000	120104.
Steel	-	-	-	—	120147.
Iron	-	-	-	—	120151.
Copper	-	-	-	—	120204.

					Temperature.	
					32°	212°
Brass	-	-	-	-	120000	120230.
Tin	-	-	-	-	—	120290.
Lead	-	-	-	-	—	120345.
Zinc	-	-	-	-	—	120360.

**EXTENSION.** (Lat.) One of the general properties of matter, being the quantity of space which a body occupies, its extremities in every direction limiting or circumscribing the matter of that body. It is the magnitude, size, or bulk of a body.

**EXTERNAL or EXTERIOR.** A term of relation applied to whatever is on the surface or outside of a body, as opposed to *internal* or *interior*.

**EXTRADOS.** The exterior curve of an arch. The term is generally used to denote the upper curve of the *voussoirs* or stones which immediately form the arch.

**EYE.** A general term signifying the centre of any part: thus the *eye of a pediment* is a circular window in its centre. The *eye of a dome* is the horizontal aperture on its summit. The *eye of a volute* is the circle at the centre, from whose circumference the spiral line commences.

**EYE, BULL'S.** See **BULL'S EYE**.

**EYEBROW.** A name sometimes given to the fillet.

## F.

**FABRIC.** (Lat.) A general term applied to a large and important building.

**FAÇADE.** (Fr.) The face or front of any building towards a street, court, garden, or other place; a term, however, more commonly used to signify the principal front.

**FACE MOULD.** The name applied by workmen to the pattern for marking the plank or board out of which ornamental hand-railings are to be cut for stairs or other works.

**FACE OF A STONE.** The surface intended for the front or outward side of the work. The back is usually left rough. Stones should be faced in the opposite direction of their splitting grain.

**FACETTES.** (Fr.) Flat projections between the flutes of columns.

**FACIA or FASCIA.** (Lat. a Band.) A flat member of an order or of a building, like a flat band or broad fillet. The architrave, when subdivided for instance, has three bands called *fasciæ*, whereof the lower is called the first fascia, the middle one the second, and the upper one the third.

**FACING.** That part in the work of a building seen by a spectator; but the term is usually employed to signify a better sort of material, which masks the inferior one used internally.

**FACTABLING.** The same as **COPING**, which see.

**FALCONETTO.** See **ARCHITECTS**, list of, 207.

**FALLING MOULDS.** The two moulds applied to the vertical sides of the railpiece, one to the convex, the other to the concave side, in order to form the back and under surface of the rail and finish the squaring.

**FALSE ATTIC.** An attic without pilasters, casements, or balustrades, used for crowning a building, as at the gates St. Denis and St. Martin at Paris.

**FALSE BEARING.** See **BEARING WALL**.

**FALSE ROOF.** That part between the ceiling of the upper floor and the covering of the roof.

**FANAL.** (Fr.) The French term for a lighthouse.

**FANUM.** (Lat.) A place consecrated to religion, including the building and ground belonging to it. Those temples erected to the memory of distinguished persons were called *fana* by the ancients.

**FARLEGH.** See **ARCHITECTS**, list of, 163.

**FARM-HOUSES.** See Book III. Chap. III. Sect. 23.

**FARRARIA.** See **GRANARY**.

**FASTIGIUM.** (Lat.) See **PEDIMENT**.

**FATHOM.** (Sax.) A measure of six feet, taken from the extent of both arms when stretched out in a right line. It is chiefly used in measuring the depth of water, quarries, wells, or pits.

**FEATHER-EDGED.** A term applied to any thin body whose section is trapezoidal; that is, thicker on one edge than on the other.

**FEATHER-EDGED BOARDS.** See **BOARDS**.

**FEATHER-EDGED COPING.** See **COPING**.

**FEEDER.** A cut or channel by which a stream or supply of water is brought into a canal. Sometimes the supply itself of the water is so called.

**FEEDING HOUSE or SHED.** A farm-building for stalling and fattening neat cattle. It

should be in a dry warm situation, capable of free ventilation, and supplied with proper conveniences for food and water.

**FELLING TIMBER.** The cutting down a full grown tree. Much difference of opinion has prevailed respecting the proper season for felling trees, some being in favour of midwinter and others of midsummer. It is however a question which principally turns upon the quantity and value of the soft or outer wood in the trunk of the tree to be felled, called *sap* by the forester and carpenter. This sap or outer wood being the only portion of the trunk in which the sap or juices of the tree circulate, if no value be set upon it, it seems of little consequence when the tree is cut down, because the mature timber, which is the really valuable part of the wood, is impermeable to the sap in its ascent through the soft wood, and is therefore in the same state at every season of the year. On the other hand, where much value attaches to the soft or outer wood, or where, as in the case of comparatively young trees, the greater part of the trunk consists of sap wood, they should be felled when the sap least circulates. The season in that case is doubtless midwinter, which, *ceteris paribus*, is certainly the best season for felling timber. The next best season seems to be midsummer, because the sap is then chiefly confined to the young shoots, to the circumference of the soft wood, and to the bark. The worst season would appear to be the spring, just before the development of the buds, when the tree is fullest of sap, and receiving fresh supplies of it from the root; and in autumn, immediately before the fall of the leaf, when there is a superabundance of sap, from its being as it were thrown out of employment by the falling of the leaf. In general all soft wood, such as elm, lime, poplar, willow, &c., should be felled during the winter. Hard woods, like the oak, beach, ash, &c., may be felled at any time, if the trunks are of large size, and chiefly valued for their heart-wood.

**FELT GRAIN.** That position of splitting timber which is cloven towards the centre of the tree, or transversely to the annular rings or plates. The transverse position, or rather that which is in the direction of the annular plates, is called the *quarter grain*.

**FELTING.** The act of splitting timber by the felt grain.

**FENCE.** (Lat. Defensio.) Any sort of construction for the purpose of enclosing land, as a bank of earth, a ditch, hedge, wall, railing, paling, &c.

**FENDER PILLS.** Those driven to protect work, either on land or in water, from the concussion of a moving body.

**FESTOON.** (Fr.) A sculptured representation of flowers, drapery, and foliage, looped or suspended at intervals on walls. The festoon was much used on friezes, altars, tablets, also over or under niches, as well as in many other situations.

**FETCHING THE PUMP.** The act of pouring water into the upper part of a pump to expel the air contained between the lower box or piston and the bottom of the pump.

**FIGURE.** In a general sense the terminating extremes or surface of a body. No body can exist without figure, or it would be infinite, and all space solid matter. Figure in geometry, any plane surface comprehended within a certain line or lines.

**FILIPPO.** See ARCHITECTS, list of, 193.

**FILLET.** (Fr. Filet.) A narrow flat band, listel, or annulet used for the separation of one moulding from another, and to give breadth and firmness to the upper edge of a crowning moulding, as in a cornice. The small bands between the flutes of a column are called fillets. See ANNULET and BAND.

**FILLET.** In carpentry or joinery, is any small timber scantling equal to or less than battens. Fillets are used for supporting the ends of boards by nailing them to joists or quarters, &c., as in *sounding boarding*, and in supporting the ends of shelves.

**FILLET GUTTER.** A sloping gutter, with a learboard and fillet thereon, to divert the water.

**FILLING IN PIECES.** In carpentry, short timbers, less than the full length, fitted against the hips of roofs, groins, braces of partitions, which interrupt the whole length.

**FINE STUFF.** Plaster used in common ceilings and walls for the reception of paper or colour. It is composed of lime slaked and sifted through a fine sieve, then mixed with a due quantity of hair and fine sand.

**FINIAL.** In Gothic architecture, the top or finishing of a pinnacle or gable, as it is now generally understood; but in ancient documents the term was used to denote an entire pinnacle.

**FINISHING.** A term frequently applied to the termination of a building; but more especially to the interior in the plasterer's work for the last coat, and often to the joiner's work, as in the architraves, bases, surbases, &c.

**FIORAVANTI.** See ARCHITECTS, list of, 159.

**FIR.** A forest tree, extensively used in building. See p. 484.

**FIR POLES.** Small trunks of fir trees, from ten to sixteen feet long, used in rustic buildings and outhouses.

**FIR IN BOND.** A technical expression to denote lintels, bond timbers, wall plates, and all timbers built in walls. See BOND.

**FIR BROUGHT.** That planed on the edges and sides.

**FIR BROUGHT AND FRAMED.** That which is both planed and framed.

**FIR BROUGHT, FRAMED, AND REBATED.** That which is planed, framed, and rebated.

**FIR BROUGHT, FRAMED, REBATED, AND BEADED.** The same as the preceding article, with the addition of beading.

**FIR FRAMED.** Rough timber framed, but which has not undergone the action of planing.

**FIR NO LABOUR.** Rough timber employed in walls, without planing or framing.

**FIRE-PLACE.** See CHIMNEY.

**FIRE-STONE.** That which resists the action of the fire. A species of it is used in joinery for rubbing away the ridges made by the cutting-edge of the plane.

**FIRMER TOOL.** A tool used by joiners. See p. 565.

**FIRST COAT.** In plastering, the laying the plaster on the laths, or the rendering, as it is called, on brickwork, when only two coats are used. When three are used, it is called *pricking-up* when upon laths, and *roughing-in* when upon bricks.

**FISCHER, VON ERLACH.** See ARCHITECTS, list of, 269.

**FISCHER, CARL.** See ARCHITECTS, list of, 313.

**FISH.** (Verb.) To secure a piece of wood by fastening another piece above or below it, and sometimes both, to strengthen it.

**FISTUCA.** (Lat.) A pile-driving instrument with two handles raised by pulleys, and guided in its descent to fall on the head of a pile so as to drive it into the ground, being what is by the workmen called a *monkey*.

**FITZ-ODO.** See ARCHITECTS, list of, 108.

**FIXTURE.** A term applied to all articles of a personal nature affixed to land. This annexation must be by the article being let into or united with the land, or with some substance previously connected therewith.

**FLAGS.** Thin stones used for paving, from one and a half to three inches thick, and of various lengths and breadths, according to the nature of the quarry.

**FLAKE WHITE.** In painting, lead corroded by the pressing of grapes, or a ceruse prepared by the acid of grapes. It is of Italian manufacture, and for the purity of its white far surpasses the white lead of this country.

**FLANK.** (Fr. Flanc.) That part of a return body which joins the front. In town houses the party-walls are the flank walls.

**FLASHING.** (Probably from Fr. Flaque, a splash.) Pieces of lead or other metal let into the joints of a wall so as to lap over the gutters or other conduit pieces, and prevent the splashing of rain injuring the interior works.

**FLAT.** That part of the covering of a house laid horizontal, and covered with lead or other material.

**FLATTING.** In house painting, a mode of painting in oil, in which the surface is left, when finished, without any gloss. The material or paint is prepared with a mixture of oil of turpentine, which secures the colours, and when used in the finishing, leaves the paint quite dead. The process is of use where it is desirable that the surface painted should retain the colour. It is only used for inside work and in the best apartments. Nut oil may be used for the purpose, so may be poppy oil, both whereof are good media for the colour.

**FLEMISH BOND.** See p. 516.

**FLEMISH BRICKS.** A species of bricks used for paving, whereof seventy-two will pave a square yard; they were originally imported from Flanders, are of a yellowish colour, and harder than common bricks.

**FLEXIBILITY.** (Lat. Flecto.) That property of bodies which admits of their bending. It is opposed to *stiffness* on the one hand, and *brittleness* on the other; stiff bodies being such as resist bending, and brittle those which cannot be bent without a disruption of their parts.

**FLEXURE.** The bending or curve of a line or surface. The point of *contrary flexure* is that point of a curve where the curvature alters from convex to concave, or the reverse, as respects the first direction of the curve.

**FLIGHT OF STEPS.** In a staircase is the series of steps from one landing place to another. Thus, the same staircase between one floor and another may consist of more than one flight of steps; the flight being reckoned from landing to landing.

**FLINT.** A material often used in inferior building. Common flints are nearly pure *silica*. They usually occur in irregular nodules in chalk. Their origin is still an unsolved geological problem.

**FLOAT.** In plastering, a long rule with a straight edge, by which the work is reduced to a plane surface.

**FLOATED LATH AND PLASTER.** Plastering of three coats, whereof the first is *pricking-up*, see Book II. Chap. III. Sect. 9.; the second, floating or floated work; and the last, of fine stuff.

**FLOATED WORK.** Plastering rendered perfectly plane by means of a **FLOAT**, which see,

**FLOATING SCREEDS.** (The etymon. of screeds, being probably *schierato*, ranged.) Strips of plaster previously set out on the work, at convenient intervals, for the *range* of the floating-rule or *float*.

**FLOOR.** (Sax. *Flope*.) The pavement or boarded lower horizontal surface of an apartment. It is constructed of earth, brick, stone, wood, or other materials. Carpenters include in the term the framed timber work on which the boarding is laid, as well as the boards themselves. In carpentry, it denotes the timbers which support the boarding, called also *naked flooring* (see p. 540.) and *carcass flooring*. The term floor is, moreover, applied to the stories of a building on the same level; thus, we have *basement floor*, *ground floor*, &c. When there is no sunk story, the ground story becomes the basement floor; the expressions, *one pair*, *two pair*, &c., implying a story above the first flight of stairs from the ground, and so on. The *principal floor* is that which contains the principal rooms; generally in country houses on the ground floor, but in those of the town mostly on the one pair floor.

**FLOOR, FOLDING OR FOLDED.** One in which the floor boards are so laid that their joints do not appear continuous throughout the whole length of the floor, but in bays or folds of three, four, five, or more boards each.

**FLOOR JOISTS** are those which support the boards of the floor; but when the floor consists of binding and bridging joists, the bridgings are never called floor joists. For the better comprehension of the different sorts of floors in carpentry, see p. 540, *et seq.*

**FLOOR STRAIGHT JOINT.** That in which the floor boards are so laid that their joints or edges form a continued line throughout the direction of their length; in opposition to *folding floor*, wherein the joints end in *folds*.

**FLOORS.** See Book II. Chap. II. Sect. 4.

**FLORED STYLE.** In Gothic architecture. See Book I. Chap. III. Sect. 5.

**FLUE.** The long open tube of a chimney from the fire-place to the top of the shaft, for voidance of the smoke. See *CHIMNEY*.

**FLUING.** The same as *SPLAYED*, which see.

**FLUSH.** (Lat. *Fluxus*.) A term used by workmen to signify a continuity of surface in two bodies joined together. Thus, in joinery, the style, rails, and munnions are usually made flush; that is, the wood of one piece on one side of the joint does not project or recede from that on the other.

**FLUSH.** In masonry or brick-work, the aptitude of two brittle bodies to splinter at the joints when the stones or bricks come in contact when contiguous in a wall.

**FLUSH.** (Verb.) A term to denote the complete bedding of masonry or brick-work, in the mortar or cement used for the connection of the stones or bricks, so as to leave no vacant space where the stones or bricks do not nicely fit in their places.

**FLUTES OR FLUTINGS.** Upright channels on the shafts of columns, usually ending hemispherically at top and bottom. Their plan or horizontal section is sometimes circular or segmental, and sometimes, as in the Grecian examples, elliptical. The Doric column (see Book III. Chap. I. Sect. 4.) has twenty round its circumference; the Ionic, Corinthian, and Composite (see Sections 5, 6, and 7. of the same Chapter) have twenty-four. The Tuscan column is never fluted. Flutes are occasionally *cabled*. See *CABLE*.

**FLYERS.** Steps in a flight of stairs that are parallel to each other.

**FLYING BUTTRESS.** A buttress in the form of an arch, springing from a solid mass of masonry, and abutting against the springing of another arch which rises from the upper points of abutment of the first. It is employed in most of the cathedrals, and its office is to act as a counterpoise against the vaulting of the nave. If flying buttresses were built solid from the ground, it is obvious that they would interfere with the vista along the aisles of the church; hence the project of continuing a resistance by means of arches. Their stability depends on the resistance afforded by the weight of the vertical buttress, whence they spring. See *ARC-BOUTANT* and *BUTTRESS*.

**FOCUS.** In geometry and the conic sections, a point on the concave side of a curve, to which the rays are reflected from all points of such curve.

**FODDER OR FOTHEL.** A weight among the plumbers of London of 19½ cwt.

**FŒNILLA.** (Lat.) See *GRANARY*.

**FOIX, DE.** See *ARCHITECTS*, list of, 245.

**FOLD OF A FLOOR.** See *FLOOR*.

**FOLDED FLOOR.** See *FLOOR*.

**FOLDING DOORS.** Such as are made to meet each other from the opposite jambs to which they are hung; and when they are rebated together, their edges meet folding over each other, with a bead at the joint, to give the appearance of one entire door.

**FOLDING JOINT.** A joint made like a rule-joint or the joint of a hinge.

**FOLIAGE.** A sculptured group of the leaves of plants and flowers, so arranged as to form architectural ornaments, as in friezes, panels, &c., and in the capitals of the Corinthian and Composite orders.

**FONT.** A vessel, generally of stone or water, for containing the water of baptism in the

Christian church. Some of the early fonts are extremely beautiful, and wrought with extraordinary richness of decoration. The singular inscription frequently found on the walls of baptisteries occurs also occasionally on ancient fonts: NIVON ANOMHMATA MH MONAN OWIN, which, reading equally well both ways, admonishes the reader to cleanse himself from sin, not less than to use the outward ceremony of baptism.

FONTANA, CARLO. See ARCHITECTS, list of, 266.

FONTANA, DOM. See ARCHITECTS, list of, 242.

FOOT. (Germ. fuss.) A measure of length, but used also in a sense which expresses surface and solidity. Thus we say, a foot *superficial* and a foot *cube*. As this term is used in almost all languages as a linear measure, it has doubtless been derived from the length of the human foot. It seems in all other countries, as in England, to be divided into twelve equal parts, or inches.

The English standard foot (31 Edw. 1.) is = 12 lineal English inches = 36 barley-corns = 16 digits = 4 palms = 3 hands =  $5\frac{1}{2}$  nails =  $1\frac{1}{2}$  spans = 1.5151 Gunter's links = .938306 ft. of France = .3047 met. of France. The foot is divided by geometers into 10 digits, and each digit into 10 lines, &c. The French, as the English, divide the foot into 12 inches, and the inch into 12 lines. The foot square or superficial is a foot each way, and contains, therefore,  $12 \times 12 = 144$  superficial inches = 2.295684 square links. The glazier's foot in Scotland = 64 square Scotch inches.

The length of the foot varies in different countries. The Paris royal foot exceeds that of England by  $9\frac{1}{2}$  lines. The ancient Roman foot of the Capitol consisted of 4 palms =  $11\frac{1}{10}$  English inches. The Rhinland or Leyden foot, used by the northern nations of Europe, is to the Roman foot as 950 to 1000. The following table exhibits the length of the foot in the principal places of the Continent, the English foot being divided into 1000 parts, or 12 inches:—

Country.	Parts.	Ft. In. Lines.
London - - - - -	1000	0 12 0
Amsterdam - - - - -	942	0 11 2
Antwerp - - - - -	946	0 11 3

— from the monument of Statilius - - - - -	972	0.11 7

Mr. Raper (*Philos. Trans.* vol. li.), from various authorities, determines the mean of the Roman foot to be nearly 968 parts of the London foot; and he considers that before the reign of Titus the Roman foot exceeded  $\frac{270}{1000}$  of the London foot, and afterwards, in

the reigns of Severus and Diocletian, it fell short of 965. Cagnazzi, from examination of the monuments of antiquity in Herculaneum and Pompeii, determines the Roman foot at 29624 metre, which, the metre being 3·2808992 English feet, would make the old Roman foot  $\frac{7}{1000}$  of the English foot.

The Scotch is to the English foot as 1·066 to 1·000, being, in fact, the French foot.

See MEASURES.

**FOOT OF THE EYE DIRECTOR.** In perspective, that point in the directing line made by a vertical plane passing through the eye and the centre of the picture.

**FOOT OF A VERTICAL LINE.** In perspective, that point in the intersecting line which is made by a vertical plane passing through the eye and the centre of the picture.

**FOOT PACE OR HALF PACE.** That part of a staircase whereon, after the flight of a few steps, you arrive at a broad place on which you may take two or three paces before you come to another step. If it occur at the angle turns of the stairs, it is called a *quarter pace*.

**FOOTING BEAM.** The name given, in some of the provinces, to the tie beam of a roof.

**FOOTINGS OF A WALL.** Projecting courses of stone at the base of a wall or building to spread the base, and give it security.

**FORCE.** In mechanics, the course of motion in a body when it begins to move, or when it changes its direction from the course in which it was previously moving. While a body remains in the same state, whether of rest or of uniform and rectilinear motion, the cause of its so remaining is in the nature of the body, which principle has received the name of *inertia*. For the laws on the composition and resolution of forces, see p. 381, *et seq.*

**FORCE PUMP.** See p. 584.

**FORCER.** In mechanics, a solid piston applied to pumps for the purpose of producing a constant stream, or of raising water to a greater height than it can be raised by the pressure of the atmosphere.

**FORE FRONT.** The principal or entrance front of a building.

**FORE PLANE.** In carpentry and joinery, the first plane used after the saw or axe.

**FORESHORTEN.** In perspective, the diminution which the representation of the side or part of a body has, in one of its dimensions, compared with the other, occasioned by the obliquity of the corresponding side or part of the original body to the plane of projection.

**FORM.** The external appearance or disposition of the surfaces of a body, in which sense it is synonymous with *FIGURE*, which see.

**FORMENT.** See ARCHITECTS, list of, 221.

**FORUM.** (Lat.) In ancient architecture, a public market; also a place where the common courts were held, and law pleadings carried on. The fora of the Romans were large open squares surrounded by porticoes, parts whereof answered for market-places, other parts for public meetings of the inhabitants, and other parts for courts of justice; the forum was also occasionally used for shows of gladiators. There were in Rome seventeen; of these fourteen were for the sale of goods, provisions, and merchandise, and called *Fora Venalia*; the other three were for civil and judicial proceedings, and called *Fora Civilia et Judicialia*. Of the latter sort was the forum of Trajan, of which the Trajan column formed the principal ornament.

**FOUNDATION.** (Fr. *Fondation*.) The lower part of a wall on which an insistent wall is raised, than which, too, it is always much thicker. See Book II. Chap. III. Sect. 1.

**FOUNDRY.** A building in which various metals are cast into moulds or shapes. See Book II. Chap. III. Sect. 11.

**FOUNTAIN.** (Lat. *Fons*.) Any natural or artificial apparatus by means whereof water springs up. In natural fountains the ascensional effect is produced by the hydrostatic pressure of the water itself; in artificial fountains, by the same sort of pressure, or by that of compressed air, and sometimes by machinery.

**FOX TAIL WEDGING.** A method of fixing a tenon in a mortise by splitting the end of the tenon and inserting a projecting wedge, then entering the tenon into the mortise, and driving it home. The bottom of the mortise resists the wedge, and forces it further into the tenon, which will expand in width, so as not only to fill the cavity at the bottom, but be firmly compressed by the sides of the mortise.

**FRAME AND FRAMING.** (Sax. *Framman*, to form.) The rough timber work of a house, including floors, roofs, partitions, ceilings, and beams. Generally, any pieces of wood fitted together with mortises and tenons are said to be framed, as doors, sash-frames, sashes, &c.

**FRANKING.** A term used by the makers of window-sashes, and applied to the mode of forming the joint when the cross-pieces of the frame intersect each other, no more wood being cut away than is sufficient to show a mitre.

**FREE STONE.** Any stone which works freely, such as Portland stone, Bath stone, the limestones generally, &c.

**FREEZE.** See FRIeze.

**FRENCH ARCHITECTURE.** See Book I. Chap. II. Sect. 17.

**FRENCH CASEMENTS.** Windows turning upon two vertical edges attached to the jambs, which, when shut, lap together upon the other two parallel edges, and are fastened by

means of long bolts extending their whole height. French casements are made in the form of the old English window, the two meeting styles, which lap together, forming a munion about 4 inches in breadth. The lower part only is moveable, the upper being fixed, and having a corresponding munion: the lower rail of the fixed part and the upper rail of the moveable part forming a transom.

**FRESCO PAINTING.** (It. *Fresco*, fresh.) A method of painting by incorporating the colours with plaster before it is dry, by which it becomes as permanent as the wall itself.

**FRETTE or FRET.** A species of ornament consisting of one or more small fillets meeting

Fig. 1044.

in vertical and horizontal directions. (See *fig. 1044.*) The sections of the channels between the fillets is rectangular.

**FRICTION.** (Lat. *Fricio*, I rub.) The resistance produced by the rubbing of the surfaces of two solid bodies against each other.

**FRIEZE, FREEZE, or FRIZE.** (Ital *Fregio*, adorned.) That member in the entablature of an order between the architrave and cornice. It is always plain in the Tuscan; ornamented with triglyphs and sculpture in the Doric; in the modern or Italian Ionic it is often swelled, in which case it is said to be *pulvinated* or *cushioned*; and in the Corinthian and Composite it is variously decorated, according to the taste of the architect.

**FRIEZE OF THE CAPITAL.** The same as the *HYPOTRACHELIUM*, which see.

**FRIEZE PANEL.** The upper panel of a six-panelled door.

**FRIEZE RAIL.** The upper rail but one of a six-panelled door.

**FRIGIDARIUM.** In ancient architecture, the apartment in which the cold bath was placed.

The word is sometimes used to denote the cold bath itself.

**FRIZE or FRISZ.** See *FRIEZE*.

**FRONT.** (Lat. *Frons*.) Any side or face of a building, but more commonly used to denote the entrance side.

**FRONTINUS.** See *ARCHITECTS*, list of, 46.

**FRONTISPIECE.** (Lat. *Frons* and *Inspicio*.) The face or fore-front of a house, but the term is more usually applied to the decorated entrance of a building.

**FRONTON.** The French term for a pediment.

**FROSTED.** A species of rustic-work, imitative of ice, formed by irregular drops of water.

**FROWCESTER.** See *ARCHITECTS*, list of, 150.

**FROWEY TIMBER.** Such as works freely to the plane without tearing, whose grain therefore is in the same direction.

**FRUSTUM.** (Lat.) In geometry, the part of a solid next the base, formed by cutting off the top, or it is the part of any solid, as a cone, a pyramid, &c., between two planes, which may be either parallel or inclined to each other.

**FUCCIO.** See *ARCHITECTS*, list of, 122.

**FUGA.** See *ARCHITECTS*, list of, 295.

**FULCRUM.** (Lat.) In mechanics, the fixed point about which a lever moves.

**FUNNEL.** (Lat. *Infundibulum*.) That part of a chimney contained between the fire-place and the summit of the shaft. See *CHIMNEY*.

**FURNACE.** (Lat. *Fornax*.) An apparatus wherein is formed a cavity to contain combustible matter, which in various ways is supplied with air, to facilitate its combustion. The two classes into which furnaces are divided are air or wind furnaces and blast furnaces. In the former, the air is conducted through the fire by the draught of a funnel or chimney communicating with it; in the latter, the action of bellows, or some other pneumatic apparatus, supplies the air. The word furnace has generally, however, a more circumscribed application, being applied usually to an apparatus for the fusion of metals, or to that used in a chemical laboratory.

**FURNITURE.** (Fr. *Fournir*, to furnish.) The visible brass work of locks, knobs to doors, window-shutters, and the like.

**FURRING.** (Fr. *Fourrer*, to thrust in.) The fixing of thin scantlings or laths upon the edges of any number of timbers in a range, when such timbers are out of the surface they were intended to form, either from their gravity, or in consequence of an original deficiency of the timbers in their depth. Thus the timbers of a floor, though level at first, oftentimes require to be furred; the same operation is frequently necessary in the reparation of old roofs, and the same work is required sometimes in new as well as old floors.

**FURRINGS.** The pieces of timber employed in bringing any piece of work in carpentry to a regular surface when the work is uneven, either through the sagging of the timber or other causes.

**FUSAROLE.** (It.) A member whose section is that of a semicircle carved into beads. It is

generally placed under the echinus, or quarter round of columns in the Doric, Ionic, and Corinthian orders.

**FUSSITIUS.** See **ARCHITECTS**, list of, 39.

**FUST.** (Fr. *Fût.*) The shaft of a column or trunk of a pilaster.

**FUST.** A term used in Devonshire, and, perhaps, in some other counties, to signify the ridge of a house.

## G.

**GABLE.** (Brit. *Gavel.*) The vertical triangular piece of wall at the end of a roof, from the level of the eaves to the summit.

**GABRIEL, J. A.** See **ARCHITECTS**, list of, 297.

**GABRIEL, JACQUES.** See **ARCHITECTS**, list of, 277.

**GAGE, or GAUGE.** (Sax. *Læssian*, to bind or confine.) In carpentry or joinery, an instrument for drawing one or more lines on any side of a piece of stuff parallel to one of the arrisses of that side. Of this tool there are four sorts; the common gage and the flooring gage (which are both applied to the drawing of a line parallel to an arris), the internal gage, and the mortise and tenon gage.

This term is also used to signify the length of a slate or tile below the lap; also the measure to which any substance is confined. It is, moreover, used by plasterers to signify a greater or less quantity of plaster of Paris used with common plaster to accelerate its setting.

**GAIN.** In carpentry, the bevelled shoulder of a binding joist, for the purpose of giving additional resistance to the tenon below.

**GAINSBOROUGH.** See **ARCHITECTS**, list of, 145.

**GAINZA.** See **ARCHITECTS**, list of, 222.

**GALILEE.** A porch usually built near the west end of abbey churches, where the monks collected in returning from processions, where bodies were laid previous to interment, and where females were allowed to see the monks to whom they were related, or to hear divine service. The galilees of Durham and Ely are found in the situation here described. The former is highly ornamented, and is eighty by fifty feet, and divided into five aisles by clustered columns and semicircular arches. The date of its erection was towards the end of the twelfth century. That of Ely Cathedral is much smaller. It is still used as the principal entrance to the church, and is without columns or other internal support. The porch at the south end of the great transept at Lincoln Cathedral is also sometimes called a galilee. The word has been frequently used, but improperly, to designate the nave of a church. Many conjectures have been made on the origin of this term, but the most commonly received opinion, founded on a passage in the writings of St. Gervase of Canterbury, is, that when a female applied to see a monk, she was directed to the porch of the church, and answered in the words of Scripture, "He goeth before you into Galilee, there shall you see him."

**GALILEL.** See **ARCHITECTS**, list of, 275.

**GALLERY.** (Fr. *Galerie.*) An apartment of a house, for different purposes. A common passage to several rooms in any upper story is called a gallery. A long room for the reception of pictures is called a picture gallery. The platform on piers, or projecting from the wall of a church and open in front to the central space is also called a gallery. The Whispering Gallery at St. Paul's is another example of the various uses of the word. The whole or a portion of the uppermost story of a theatre is likewise called a gallery. The term is, moreover, used to denote porticoes formed with long ranges of columns on one side.

**GALLI.** See **ARCHITECTS**, list of, 276.

**GANDON.** See **ARCHITECTS**, list of, 315.

**GAOL.** A prison, or place of legal confinement. See **Book III. Chap. III. Sect. 18.**

**GARDEN SHEDS.** Erections for containing garden implements, flower-pots, hot-bed frames, and glass sashes, &c.; also for working in during bad weather. They are best placed on the back wall of the tool-house, and thus hold the furnaces, fuel, and other articles.

**GARLANDS.** (Fr.) Ornaments of flowers, fruit, and leaves anciently used at the gates of temples where feasts or solemn rejoicings were held.

**GARNETS, CROSS.** A species of hinge used in the most common works, formed in the shape of the letter T turned thus , the vertical part being fastened to the style or jamb of the doorcase, and the horizontal part to the door or shutter.

**GARRET.** The upper story of a house taken either partially or wholly from the space within the roof.

**GARZIA.** See **ARCHITECTS**, list of, 232.

**GATE.** (Sax. *Leat.*) A large door, generally framed of wood. The width of gates should be from eight and a half to nine feet, and the height from five to eight feet. The materials of gates should be well seasoned previous to use, otherwise they will be soon injured by the sun and wind. The parts should be also very correctly put together. For durability,

- oak is the best ; but some of the lighter woods, as deal, willow, and alder, are, on account of their lightness, occasionally used. These, however, are more for field-bar gates than close gates.
- GAUGE.** See **GAGE**.
- GAVEL.** The same as **GABLE**, which see.
- GATHERING OF THE WINGS.** See **CHIMNEY**.
- GENERATING CURVE.** See **EVOLUTE**.
- GENERATING LINE or PLANE.** In geometry, a line or plane which moves according to a given law, either round one of its extremities as a fixed point or axis, or parallel to itself, in order to generate a plane figure, or solid, formed by the space it has gone over.
- GENESIS.** (Gr.) In geometry, the formation of a line, plane, or solid, by the motion of a point, line, or plane. See **GENERATING LINE**.
- GENGA.** See **ARCHITECTS**, list of, 212.
- GEOMETRICAL.** That which has a relation to geometry.
- GEOMETRICAL STAIRCASE.** That in which the flight of stairs is supported by the wall at one end of the steps.
- GEOMETRY.** (Gr.  $\Gamma\eta$ , the earth, and  $\text{Μετρον}$ , I measure.) That science which treats of the objects of figured space. Its etymology implies the object of measuring land, that, as it is said, being its first application in Egypt, where it is pretended to have been invented, for ascertaining the landmarks after the yearly recession of the inundations of the Nile, in order to mark the proper allotment of each owner. Whatever the origin, however, of the term, the occasions on which it is necessary to compare things with one another in respect of their forms and magnitudes are so numerous in every stage of society, that a geometry more or less perfect must have existed from the first periods of civilisation. See Book II. Chap. I. Sect. 2.
- GEOMETRY, DESCRIPTIVE.** The art of representing a definite body upon two planes at right angles with each other, by lines falling perpendicularly to the planes from all the points of concurrence of every two contiguous sides of the body, and from all points of its contour, and, *vice versa*, from a given representation to ascertain the parts of the original objects. See Book II. Chap. I. Sect. 6.
- GEOMETRY, PRACTICAL.** See Book II. Chap. I. Sect. 3.
- GERMAIN, St.** See **ARCHITECTS**, list of, 57.
- GIBBS, J.** See **ARCHITECTS**, list of, 281.
- GIBBS, W.** See **ARCHITECTS**, list of, 188.
- GIBBLEA CHEQUE.** A term used by Scotch masons to denote the cutting away of the right angle formed by the front and returns of the aperture of a stone door-case, in the form of a rebate or reveal, so as to make the outer side of the door or closure flush with the face of the wall.
- GILDING.** The practice of laying gold leaf on any surface. See Book II. Chap. III. Sect. 12.
- GILL.** A measure equal to one fourth of a pint.
- GIMBALS, GIMBOLS, or GIMBLES.** (Lat. *Gemellus*.) A piece of mechanism consisting of two brass hoops or rings which move within one another, each perpendicularly to its plane, about two axes at right angles to each other. A body suspended in this manner, having a free motion in two directions at right angles, assumes a constantly vertical position.
- GIMLET, or perhaps more properly GIMBLET.** (Fr. *Guimbelet*.) A piece of steel of a semi-cylindrical form, hollow on one side, having a cross handle at one end and a worm or screw at the other. Its use is to bore a hole in a piece of wood. The screw draws the instrument into the wood when turned by the handle, and the excavated part, forming a sharp angle with the exterior, cuts the fibres across, and contains the core of the wood cut out.
- GIOCONDO.** See **ARCHITECTS**, list of, 182.
- GIORGIO, DL.** See **ARCHITECTS**, list of, 161.
- GIOVAN BAPTISTA DI TOLEDO.** See **ARCHITECTS**, list of, 234.
- GIOVANNI DA PISA.** See **ARCHITECTS**, list of, 129.
- GIRDER.** (Sax. *Lýnðan*, to enclose.) The principal beam in a floor, for supporting the binding or other joists, whereby the bearing or length is lessened. Perhaps so called because the ends of the joists are enclosed by it.
- GIRDELE.** A circular band or fillet surrounding a part of a column.
- GIRT.** The length of the circumference of an object, whether rectilinear or curvilinear, on its horizontal section. In timber measuring, according to some, is taken at one fourth of the circumference of the tree, and is so taken for the side of a square equal in area to the section of the tree cut through, where the perimeter is taken in order to obtain the girt.
- GLASS.** (Germ.) A transparent, impermeable, and brittle substance, whereof the different sorts used in building are described, Book II. Chap. II. Sect. 11.
- GLASS PAINTING.** A decoration frequently used in buildings, is the method of staining

glass in such a manner as to produce the effect of representing all the subjects whereof the art is susceptible. A French painter of Marseilles is said to have been the first who instructed the Italians in this art, during the pontificate of Julius II. It was, however, practised to a considerable extent by Lucas of Leyden and Albert Durer. The different colours are prepared as follows:—*Black* is produced by two thirds of iron scales or flakes, and the other third of small glass beads, or a substance called *rocagliu* by the Italians. *White* is prepared for by sand or small white pebbles calcined, pounded, and then finely ground. One fourth part of saltpetre is added, and the mixture is then again calcined and pulverised, to which a little gypsum or plaster of Paris is added. *Yellow* is formed from leaf silver, ground and mixed in a crucible with saltpetre or sulphur; then ground on a porphyry stone, and lastly, again ground with nine times the quantity of red ochre. *Red*, one of the most difficult of the colours to make, is prepared from litharge of silver and iron scales, gum Arabic, ferretta, glass beads, and bloodstone, in nearly equal quantities. Great experience is necessary to succeed in making this colour. *Green* is produced from os ustum one ounce, the same quantity of black lead, and four ounces of white lead, incorporated by the action of fire. When calcined, a fourth part of saltpetre is added, and, after a second calcination, a sixth more; after which a third coction is made before using it. *Azure, purple, and violet* are prepared in a similar manner to green, omitting the os ustum, and in its stead using sulphur for azure, perigueux for purple, and both these drugs for violet. *Carnations*, which are compounded colours, are calcined, and usually mixed with water. They must be finished part by part, and each with great dispatch, before the plaster dries, for there is little opportunity for blending. The lights cannot be heightened, but the shadows may, when they begin to dry, be a little strengthened. Promptitude and facility in execution are the great requisites for this method of painting.

**GLASS PLATE.** Glass cast in plates and polished. See p. 510.

The following is the Tariff of the Thames Plate Glass Company, Savoy Wharf, Strand, for Glass, since 1845, when the Duty was taken off:—

Feet Super.	£	s.	d.	Feet Super.	£	s.	d.	Feet Super.	£	s.	d.

30	-	24	14	60	-	73	4	90	-	173	10

The above are the prices for glazing glass. For glass to be silvered, the prices are somewhat higher. The cost of silvering is  $12\frac{1}{2}$  per cent. under 50*l.* value, and 20 per cent. above that value.

**GLAZIER.** An artisan whose employment is that of fitting and fixing the glass employed in a building. See Book II. Chap. III. Sect. 8.

**GLUE** (from the Lat. *Gluten*.) A tenacious viscid matter made of the skins and hoofs of animals, for cementing two bodies together. Glue is bought in cakes, and is better the older the skin of the animal from which it is made. That which swells without dissolving when steeped in water is the best. To prepare glue it should be broken into small fragments and then steeped in water about twelve hours. It should be then heated in a leaden or copper vessel till the whole is dissolved, stirring it frequently with a stick. After this it is put into a wooden vessel and remains for use. Good glue for external work is made by grinding as much white lead with linseed oil as will just make the liquid of a whitish colour, and strong but not thick.

- GLYPH.** (Gr. Γλυφω, I carve.) A sunken channel, the term being usually employed in reference to a vertical one. From their number, those in the Doric order are called triglyphs.
- GLYPTOTHECA.** (Gr. Γλυφω, and Θηκη, deposit.) A building or room for the preservation of works of sculpture.
- GNEISS.** A species of granite which, from excess of mica, is generally of a lamellar or slaty texture. It is a term used by the miners of Germany.
- GNOMON.** (Gr. Γνωμων.) An instrument for measuring shadows, and thereby determining the sun's height. In dialling, it is the style of the dial, and its shadow marks the hour. It is placed so that its straight edge is parallel to the axis of the earth's rotation. In geometry, a gnomon is that part of a parallelogram which remains when one of the parallelograms about its diagonal is removed; or the portion of the parallelogram composed of the two complements and one of the parallelograms about the diagonal. The term is found in Euclid, but is now rarely used.
- GOCCIOLATOIO.** The same as CORONA, which see.
- GOLA, or GULA.** (It.) The same as CYMA, which see.
- GOLDCLIFF.** See ARCHITECTS, list of, 102.
- GONDUIIN.** See ARCHITECTS, list of, 312.
- GONIOMETER.** (Gr. Γωνια, an angle, and Μετρον, I measure.) An instrument for measuring solid angles.
- GONSALVO.** See ARCHITECTS, list of, 118.
- GORGE.** The same as CAVETTO, which see. The *gorgerin* is a diminutive of the term.
- GORGONEIA.** (Gr.) Key-stones carved with Gorgons' heads.
- GOTHIC ARCHITECTURE.** See Book I. Chap. II. Sect. 15.; and same Book, Chap. III. Sections 2, 3, 4, and 5.
- GOUFFING FOUNDATIONS.** A Scotch term, signifying a mode of securing unsound walls by driving wedges or pins under their foundations.
- GOUGE.** A chisel whose section is of a semicircular form.
- GOVERNMENT OFFICES.** See Book III. Chap. III. Sect. 5.
- GRADETTI.** The same as ANNULETS, which see.
- GRÆCOSTASIS.** A hall or portico adjoining the Roman comitia, in which foreign ambassadors waited before entering the senate, and also whilst waiting the answer that was to be given to them.
- GRAIN.** In wood or stone, is the line of direction in which either may be split transversely.
- GRANARY.** (Lat. Granum.) A building for storing corn, especially that intended to be kept for a considerable time. Vitruvius calls those buildings intended for the preservation of grain, *granaria*, those for hay *fenilia*, and those for straw *farraria*. The term *horreum* was used by the Romans for denoting buildings not only for the preservation of corn, but for various other effects.
- GRAND.** A term used in the fine arts, generally to express that quality by which the highest degree of majesty and dignity is imparted to a work of art. Its source is, in form, freed from ordinary and common bounds, and to be properly appreciated requires an investigation of the different qualities by which great and extraordinary objects produce impressions on the mind.
- GRANGE.** A farm-yard or farmery, consisting of a farm-house and a court of offices for the different animals and implements used in farming, as also of barns, feeding houses, poultry houses, &c.
- GRANITE.** See Book II. Chap. II. Sect. 2.
- GRATICULATION.** The division of a design or draught into squares, for the purpose of reducing it to smaller dimensions.
- GRAVEL.** A term applied to a well-known material of small stones, varying in size from a pea to a walnut, or something larger. It is often intermixed with other substances, as sand, clay, loam, flints, pebbles, iron ore, &c.
- GRAVITY.** See SPECIFIC GRAVITY.
- GRECIAN ARCHITECTURE.** See Book I. Chap. II. Sect. 11.
- GREEK CROSS.** See CROSS.
- GREEK MASONRY.** The manner of bonding walls among the Grecians. See MASONRY.
- GREENHOUSE.** A building for sheltering in pots plants which are too tender to endure the open air the greater part of the year. It is constructed with a roof and one or more sides of glass, and being one constructed for luxury should not be far away from the dwelling-house, so that the greatest enjoyment may be had from it. At the same time it should, if possible, be near the flower-garden, as being of similar character in use. The length and breadth can only be determined by the wealth and objects of the proprietor. The best aspects are south and south east, but any aspect may, in case of necessity, be taken, if the roof be entirely of glass, and plenty of artificial heat be supplied. In those greenhouses, however, which face the north, the tender plants do not in winter succeed

so well, and a greater quantity of artificial heat must then be supplied, and the plants should, in such case, be chiefly evergreens, and others that come into flower in the summer season, and grow and flower but little during the winter. The plants in greenhouses are kept in pots or boxes on stages or shelves, so as to be near and follow the slope of the roof, and thus made more susceptible of the action of the sun's rays immediately on passing through the glass.

An orangery, from being constructed with a ceiled roof, differs from a greenhouse; it is, moreover, chiefly devoted to plants producing their shoots and flowers in the summer season, and in the open air; the use of the orangery being merely to preserve them during the winter. The structure is more properly called a conservatory, though this term is now applied to buildings with glass roofs, wherein the plants are not kept in pots, but planted in the free soil, and wherein some are so reared as to grow and flower in the winter months.

**GREY STOCKS.** Bricks of the third quality of the best or malm bricks. See Book II. Chap. II. Sect. 10.

**GRINDING.** The act of taking off the redundant parts of a body, and forming it to its destined surface.

**GRINDSTONE.** A cylindrical stone, mounted on a spindle through its axis, with a winch-handle for turning it, to grind edge-tools.

**GRIT STONE.** One of various degrees of hardness; mostly of a grey, sometimes of a yellowish, colour. It is composed of a siliceous and micaceous sand, closely compacted by an argillaceous cement. It gives some sparks with steel, is indissoluble, or nearly so, in acids, and vitrifiable in a strong fire. It is used for millstones more than for building.

**GROIN.** (Sax. *lropen*, to grow.) The line formed by the intersection of two arches, which cross each other at any angle. See CROSS VAULTING, and Book II. Chap. I. Sect. 9.

**GROINED CEILING.** One formed by three or more curved surfaces, so that every two may form a groin, all the groins terminating at one extremity in a common point.

**GROOVE.** (Sax. *lrapan*, to dig.) A sunken rectangular channel. It is usually employed to connect two pieces of wood together, the piece not grooved having on its edge a projection or *tongue*, whose section corresponds to and fits the groove.

**GROTESQUE.** (Fr.) A term applied to capricious ornaments which, as a whole, have no type in nature, consisting of figures, animals, leaves, flowers, fruits, and the like, all connected together.

**GROUND JOISTS.** Those which rest upon sleepers laid upon the ground, or on bricks, prop stones, or dwarf walls; they are only used in basement and ground floors.

**GROUND LINE.** In perspective, the intersection of the picture with the ground plane. See GROUND PLANE.

**GROUND NICHE.** One whose base or seat is on a level with the ground floor.

**GROUND PLAN.** The plan of the story of a house level with the surface of the ground, or a few steps above it. It is not always the lowest floor, the basement being frequently beneath it.

**GROUND PLANE.** In perspective the situation of the original plane in the supposed level of our horizon. It differs from the horizontal plane, which is said of any plane parallel to the horizon; whereas the ground plane is a tangent plane to the surface of the earth, and is supposed to contain the objects to be represented. The term *ground plane* is used in a more confined sense than that of original plane, which may be any plane, whether horizontal or inclined.

**GROUND PLATE OF GROUND SILL.** The lowest horizontal timber on which the exterior walls of a building are erected. It chiefly occurs in timber buildings, or in buildings whose outside walls are formed of brick panels with timber framings.

**GROUND PLOT.** The plan of the walls of a building where they first commence above the foundation, though more properly it is the piece of ground selected to receive the building. For dwellings, its chief requisites are a healthy situation, a convenient supply of water, good drainage, a pleasant aspect, &c. If for trade or manufacture, it should be conveniently placed for receiving the raw material, and for exporting the articles manufactured.

**GROUNDS.** In joinery, certain pieces of wood attached to a wall, to which the finishings are fastened. Their surface is flush with the plastering. Narrow grounds are those whereto the bases and surbases of rooms are fastened. Grounds are used over apertures, as well for securing the architraves as for strengthening the plaster. That the plaster may be kept firm, should the wood shrink, a groove is sometimes run on the edge of the ground next to the plaster, or the edge of the ground is rebated on the side next to the wall, so that in the act of plastering the stuff is received into the groove or rebate, which prevents it from shifting when it becomes dry.

**GROUPED COLUMNS or PILASTERS.** A term used to denote three, four, or more columns placed upon the same pedestals. When two only are placed together they are said to be coupled.

**GROUT.** (Sax. *lput.*) A thin semi-liquid mortar, composed of quicklime and fine sand, prepared and poured into the joints of masonry and brickwork, which process is called *grouting*.

**GROWING SHORE.** See **DEAD SHORE**.

**GUDGEON.** The axle of a wheel, on which it turns and is supported. To diminish friction gudgeons are made as small as possible in diameter, consistent with their weight. They are often made of cast iron, on account of its cheapness, but wrought iron of the same dimensions is stronger, and will support a greater load.

**GUEULE.** A term synonymous with **CYMATIUM**.

**GUILLOCHE.** (Fr.) An ornament in the form of two or more bands or strings twisting over each other, so as to repeat the same figure, in a continued series, by the spiral returning of the bands. The term is applied but improperly to **FRETS**, which see.

**GULA.** Synonymous with **CYMATIUM**, which see.

**GULIELMO.** See **ARCHITECTS**, list of, 99.

**GUNDULPH.** See **ARCHITECTS**, list of, 87.

**GUNTER'S CHAIN.** One used for measuring land, and taking its name from its reputed inventor. It is 66 feet, or 4 poles, long, and divided into 100 links, each whereof is joined to the adjacent one by three rings; the length of each link, including the adjacent rings, is therefore 7.92 inches. The advantage of the measure is in the facility it affords to numerical calculation. Thus the English acre, containing 4840 yards, and Gunter's chain being 22 yards long, it follows that a square chain is exactly the tenth part of an acre, consequently the contents of a field being cast up in square links, it is only necessary to divide by 100,000, or to cut off the last five figures, to obtain the contents expressed in acres.

**GUTTÆ.** See **DROPS**.

**GUTTERS and GUTTERING.** Canals to the roofs of houses to receive and carry off rain-water. They are made either of lead or of tiles, which are either plain or concave; these last are called gutter tiles, and so adapted to each other as to be laid with great ease. The Romans had gutters of terra cotta along the roofs of their houses, and the rain-water from them ran out through the heads of animals and other devices placed in the angles and in convenient parts. Leaden gutters were known in the middle ages.

**GYMNASIUM.** (Gr. *Γυμνασιον*, from *Γυμνος*, naked.) Originally a space measured out and covered with sand for the exercise of athletic games. The gymnasias in the end became spacious buildings, or institutions, for the mental as well as corporeal instruction of youth. They were first erected at Lacedæmon, whence they spread, through the rest of Greece, into Italy. They did not consist of single edifices, but comprised several buildings and porticoes for study and discourse, for baths, anointing rooms, palastras, in which the exercises took place, and for other purposes.

**GYNÆCEUM.** (Gr. *Γυναικειον*.) In ancient architecture, that portion of the Grecian house set apart for the occupation of the female part of the family.

**GYPSUM.** (Probably from *Γη*, earth, and *Εψω*, I concoct.) Crystals of native sulphate of lime. Being subjected to a moderate heat, to expel the water of crystallisation, it forms plaster of Paris, and, coming in contact with water, immediately assumes a solid form. Of the numerous species, alabaster is, perhaps, the most abundant.

## H.

**HACKS.** In brickmaking (see p. 503.) the rows in which bricks are laid to dry after being moulded.

**HACKING.** In walling, denotes the interruption of a course of stones, by the introduction of another on a different level, for want of stones to complete the thickness. Thus making two courses at the end of a wall of the same height as one at the other. The last stone laid is often notched to receive the first stone of the other where the two heights commence. Hacking is never permitted in good work. The term is used more in Scotland than in England.

**HALF PACE.** See **FOOT PACE**.

**HALF ROUND.** A semicircular moulding, which may be a bead or torus.

**HALL.** (Sax. *Hal*.) A name applied indifferently to the first large apartment on entering a house, to the public room of a corporate body, a court of justice, or to a manor house.

Vitruvius mentions three sorts of halls: the Tetrastyle, which has four columns supporting the ceiling; the Corinthian, which has columns all round, and is vaulted; and the Egyptian, which has a peristyle of Corinthian columns, bearing a second order with a ceiling. These were called *æci*. In magnificent edifices, where the hall is larger and loftier than ordinary, and is placed in the middle of the house, it is called a saloon; and a royal apartment consists of a hall or chamber of guards, a chamber, an anti-chamber, a cabinet chamber, and a gallery.

**HALVING.** A method of joining timbers by letting them into each other. It is preferable to mortising, even where the timbers do not pass each other, as they are less liable to be displaced by shrinking.

**HAM.** (Sax.) Properly a house or dwelling place; also a street or village, whence it has become the final syllable to many of our towns, as Nottingham, Buckingham, &c.; hence, too, *hamlet*, the diminutive of *ham*, is a small street or village.

**HAMMER BEAM.** A beam acting as a tie at the feet of a pair of principal rafters, but not extending so as to connect the opposite sides. Hammer beams are used chiefly in roofs constructed after the Gothic style, the end which hangs over, being frequently supported by a concave rib springing from the wall, as a tangent from a curve, and in its turn supporting another rib, forming an arch. The ends of hammer beams are often decorated with beads and other devices.

**HAND-RAIL OF A STAIR.** A rail raised upon slender posts, called balusters, to prevent persons falling down the well hole, as also to assist them in ascending and descending.

**HANDSPIKE.** A lever for raising a weight, usually of wood, and applied to the holes in a capstan head.

**HANG OVER.** (Verb.) A term used to denote the condition of a wall when the top projects beyond the bottom.

**HANGINGS.** Linings for rooms of arras, tapestry, paper, or the like. Paper hangings were introduced early in the seventeenth century.

**HANGING STYLE OF A DOOR.** That to which the hinges are attached.

**HARLEWIN.** See ARCHITECTS, list of, 85.

**HARMONICAL PROPORTION.** That which, in a series of quantities, any three adjoining terms being taken, the difference between the first and second is to the difference between the second and third, as the first is to the third.

**HARMUS.** (Gr. *'Appos.*) In ancient architecture, a tile used for covering the joint between two common tiles.

**HARNES ROOM.** A room wherein harness is deposited. It is absolutely requisite that it be dry and kept clean. Its situation should be near the stable it is destined to serve.

**HASSACK.** The provincial name for Kentish rag stone.

**HATCHET.** (Fr. *Hachette.*) A small axe used by joiners for reducing the edges of boards.

**HAUNCHES OF AN ARCH.** The parts between the crown and the springing.

**HAWK.** A small quadrangular tool with a handle, used by a plasterer, on which the stuff required by him is served, for his proceeding with the work in progress. He has always a boy attendant on him, by whom he is supplied with the material. The boy in question is called a *Hawk-boy*.

**HAWKSMOOR.** See ARCHITECTS, list of, 273.

**HEAD.** See APERTURE.

**HEAD JERKIN.** See JERKIN.

**HEADERS.** In masonry, stones extending over the thickness of a wall; and in brick-laying, the bricks which are laid lengthwise across the thickness of the wall are called *headers*.

**HEADING COURSE.** In brickwork and masonry, that in which the length of the stone or brick is across the thickness of the wall.

**HEADING JOINT.** In joinery, the joint of two or more boards at right angles to the fibres, or in handrailing at right angles to the back; this is so disposed with a view of continuing the length of the board when too short. In good work the heading joints are ploughed and tongued, and in dados are, moreover, connected with glue.

**HEADWAY OF STAIRS.** The clear distance, measured perpendicularly, from a given landing-place or stair to the ceiling above, allowing for the thickness of the steps.

**HEADWORK.** A name by which the heads and other ornaments on the keystones of arches is frequently designated.

**HEART BOND.** In masonry, that in which two stones of a wall forming its breadth, have one stone of the same breadth placed over them. See BOND.

**HEARTH.** See CHIMNEY.

**HEATHER ROOF.** A covering used in Scotland, by some considered superior to straw.

**HEBREW ARCHITECTURE.** See Book I. Chap. II. Sect. 6.

**HECATOMFEDON.** (Gr.) A temple of a hundred feet in length. As applied to the Parthenon, for discovering the true length of the Greek foot. Stuart took considerable pains in the measurement of that temple. The results, as published by Revely, are as follow:—

	Eng. Inches.
Length of the upper step, in front of the temple, gives for one foot -	12·139
From outside to outside of the angular columns - - -	12·095
From centre to centre of the front columns - - -	12·0982
Length of the architrave - - -	12·0625

**HEEK.** The same as RACK.

**HEEL.** A term used by workmen to denote a *cyma reversa*.

**HEEL OF A RAFTER.** The end or foot that rests on the wall plate.

**HEIGHT.** The perpendicular distance of the most remote part of a body from the plane on which it rests.

**HEIGHT OF AN ARCH.** A line drawn from the middle of the chord or span to the intrados.

**HELICAL LINE OF A HANDRAIL.** The spiral line twisting round the cylinder, representing the form of the handrail before it is moulded.

**HELIOCAMINUS.** (Gr. *ἥλιος*, the sun, and *καμινος*, a furnace.) A chamber in the Roman houses which depended on the rays of the sun for warming it.

**HELIX.** (Gr. *ἥλιξ*, a kind of ivy whose stalk curls.) A small volute or twist under the abacus of the Corinthian capital, in which there are, in every perfect capital, sixteen, called also *urilleæ*; viz. two at each angle, and two meeting under the middle of the abacus, branching out of the caulicoli or stalks, which rise from between the leaves.

**HELPSTONE.** See ARCHITECTS, list of, 135.

**HEM.** The spiral projecting part of the Ionic capital.

**HEMICIRCLE.** A semicircle; the term is used architecturally to denote vaults of the cradle form, and arches or sweeps of vaults, constituting a semicircle.

**HEMISPHERE.** In geometry, the half of a globe or sphere, when divided by a plane passing through its centre.

**HEMITRIGLYPH.** A half triglyph.

**HENRY OF BLOIS.** See ARCHITECTS, list of, 92.

**HENRY LATOMUS.** See ARCHITECTS, list of, 134.

**HEPTAGON.** (Gr.) A geometrical figure of seven sides and angles.

**HERMITAGE.** A small hut, or dwelling in an unfrequented place, occupied by a hermit.

**HERMODORUS.** See ARCHITECTS, list of, 30.

**HERMOGENES.** See ARCHITECTS, list of, 2.

**HERRERA.** See ARCHITECTS, list of, 236.

**HERRING BONE WORK.** A disposition of bricks or stones laid diagonally (see diagram in the margin), each length receiving the end of the adjoining brick or stone. See ASHLAR.

**HEWN STONE.** That which is reduced to a given form by the use of the mallet and chisel.

**HEXAEDRON OR CUBE.** (Gr. *ἕξ*, six, and *ἔδρα*, seat.) One of the five regular solids, so called from its having six faces or seats.

**HEXAGON.** (*ἕξ* and *γωνία*, angle.) In geometry, a plain figure bounded by six straight lines, which, when equal, constitute the figure a regular hexagon.

**HEXASTYLE.** (Gr. *ἕξ* and *ἑτάλος*, column.) That species of temple or building having six columns in front. See COLONADE.

**HICK-JOINT POINTING.** That species of pointing in which, after the joints are raked out, a portion of superior mortar is inserted between the courses, and made perfectly smooth with the surface. See POINTING.

**HIEROGLYPHICS.** (*ἱερός*, sacred, and *ἑλκεῖν*, I engrave.) Sculpture or picture writing, which has obtained the name from being most commonly found on sacred buildings. They consist in the expression of a series of ideas by representations of visible objects. The name is, however, more particularly applied to a species of writing used by the ancient Egyptians, which, according to Champollion, was of three different varieties of characters: — 1. The hieroglyphic, properly so called, wherein the representation of the object conveys the idea of the object itself. 2. That in which the characters represent ideas by images of visible objects used as symbols. 3. That consisting of *phonetic characters*, in which the sign does not represent an object but a sound.

**HINDOO ARCHITECTURE.** See INDIAN ARCHITECTURE, Book I. Chap. II. Sect. 6.

**HINGES** (from *Hang*). The metal joints upon which any body turns, such as doors, shutters, &c. There are many species of hinges, which are described in Book II. Chap. III. Sect. 5.

**HIP.** A piece of timber placed between every two adjacent inclined sides of a hip roof, for the purpose of receiving what are called the jack rafters.

**HIP MOULD.** A term used by some workmen to denote the back of the hip; by others it is used to signify the form or pattern by which the hip is set out.

**HIP OR HIPPED ROOF.** A roof whose return at the end of a building rises immediately from the wall plate with the same inclination as the adjacent sides. The back of a hip is the angle made on its upper edge, to range with the two sides or planes of the roof, between which it is placed. The *jack rafters* are those short rafters which are shorter than the full-sized ones to fill in against the hips.

**HIP OR CORNER TILES** are those used at the hips of roofs; they are ten inches long, and of appropriate breadth and thickness, and bent on a mould before burning.

**HIPPODROME.** (Gr. *ἵππος*, a horse, and *δρομος*, a course.) In ancient architecture, a place

- appropriated by the Greeks to equestrian exercises, and one in which the prizes were contended for. The most celebrated of these was at Olympia. It was four stadia (each 625 feet) long, and one stadium in breadth.
- HOARD.** (Sax. *Hopð*, to keep.) A timber enclosure round a building, in the course of erection or under repair.
- HOB.** An utensil employed by labourers for carrying mortar or bricks.
- HOLDFAST.** A long nail, with a flat short head for securing objects to a wall.
- HOLLAND.** See ARCHITECTS, list of, 307.
- HOLLOW.** A concave moulding, whose section is about the quadrant of a circle; called, sometimes, by the workmen a *casement*.
- HOLLOW NEWEL.** An opening in the middle of a staircase. The term is used in contradistinction to solid newel, into which the ends of the steps are built. In the hollow newel, or well hole, the steps are only supported at one end by the surrounding wall of the staircase, the ends next the hollow being unsupported.
- HOLLOW QUIINS.** Piers of brick or stone made behind the lock gates of canals.
- HOLLOW WALL.** One built in two thicknesses, leaving a cavity between them for the purpose of saving materials, or for preserving an uniform temperature in an apartment.
- HOMESTALL.** A mansion house, or seat in the country.
- HOMOLOGOUS.** In geometry, the correspondent sides of similar figures. The areas and solid contents of such figures are likewise homologous.
- HONTANON, GIOV. GIL. DE.** See ARCHITECTS, list of, 205.
- HONTANON, RODERIGO, GIL. DE.** See ARCHITECTS, list of, 208.
- HOO.** See ARCHITECTS, list of, 114.
- HOOK.** (Sax. *Hoce*.) A bent piece of iron, used to fasten bodies together, or whereon to hang any article. They are of various kinds.
- HOOKS.** See ARCHITECTS, list of, 265.
- HOOKPINS.** The same as DRAW BOREPINS, which see.
- HORIZONTAL CORNICE.** The level part of the cornice of a pediment under the two inclined cornices.
- HORIZONTAL LINE.** In perspective, the vanishing line of planes parallel to the horizon.
- HORIZONTAL PLANE.** A plane passing through the eye parallel to the horizon, and producing the vanishing line of all level planes.
- HORIZONTAL PROJECTION.** The projection made on a plane parallel to the horizon. This may be understood perspectively, or orthographically, according as the projecting rays are directed to a given point, or perpendicular to a given point.
- HORN.** A name sometimes given to the Ionic volute.
- HORREUM.** See GRANARY.
- HORSE BLOCK.** A square frame of strong boards, used by excavators to elevate the ends of their wheeling planks.
- HORSE RUN.** A contrivance for drawing up loaded wheelbarrows of soil from the deep cuttings of foundations, canals, docks, &c., by the help of a horse, which goes backwards and forwards instead of round, as in a *horse-gin*.
- HORSESHOE ARCH.** See p. 55.
- HORWOOD.** See ARCHITECTS, list of, 152.
- HOSPITAL.** See Book III. Chap. III. Sect. 17.
- HOSTEL OR HOTEL.** (Fr.) Among us this word is used to denote a large inn, or place of public entertainment; but on the Continent it is also used to signify a large house or palace.
- HOT HOUSE.** A general term for the glass buildings used in gardening, and including stoves, greenhouses, orangeries, and conservatories. Pits and frames are mere garden structures, with glass roofs, the sides and ends being of brick, stone, or wood, but so low as to prevent entrance into them; they cannot therefore be considered as hot-houses.
- HOUSE.** (Germ. *Hause*.) A human habitation or place of abode of a family. Among the nations of the east and of the south, houses are flat on the top, to which ascent is general on the outside. As we proceed northward, a declivity of the roof becomes requisite to throw off the rain and snow, which are of greater continuance in higher latitudes. Amongst the ancient Greeks, Romans, and Jews, the houses usually enclosed a quadrangular area or court, open to the sky. This part of the house was by the Romans called the *impluvium* or *cavadium*, and was provided with channels to carry off the waters into the sewers. Both the Roman and Greek house is described by Vitruvius, to whose work we must refer the reader for further information on these heads. The word house is used in various ways; as in the phrase, "a religious house," either the buildings of a monastery, or the community of persons inhabiting them may be designated. In the middle ages, when a family retired to the lodge connected with the mansion, or to their country seat, it was called "keeping their secret house." Every gradation of building for habitation, from the cottage to the palace, is embraced by the word house, so that to

- give a full account of the requisites of each would occupy more space than could be devoted to the subject in this place ; the reader must therefore refer to Book III. Chap. III. Sects. 20 to 24. inclusive.
- HOUSING.** The space taken out of one solid for the insertion of the extremity of another, for the purpose of connecting them. Thus the string board of a stair is most frequently notched out for the reception of the steps.
- HOVEL.** An open shed for sheltering cattle, for protecting produce or materials of different kinds from the weather, or for performing various country operations during heavy rains, falls of snow, or severe frosts.
- HOVELLING.** A mode of preventing chimneys from smoking, by carrying up two sides higher than those less liable to receive strong currents of air ; or apertures are left on all the sides, so that when the wind blows over the top, the smoke may escape below.
- HUE.** In painting, any degree of strength or vividness of colour, from its greatest or deepest to its weakest tint.
- HUNDRED OF LIME.** A denomination of measure which, in some places, is equal to thirty-five, in others to twenty-five, heaped bushels or bags, the latter being the quantity about London, that is, one hundred pecks. The *hundred* is also used for numbering, thus deals are sold by the *long hundred*, or six score. Pales and laths are sold at five score to the hundred if five feet long, and six score if only three feet long. The *hundred weight* is 112 lbs. avoirdupois ; the *long hundred weight* is 120 lbs. ; so that the former is to the latter as '93333 to 1.
- HUNG, DOUBLE AND SINGLE.** A term applied to sashes ; the first when both the upper and lower sash are balanced by weights, for raising and depressing, and the last when only one, usually the lower one, is balanced over the pulleys.
- HUT.** A small cottage or hovel, generally constructed of earthy materials, as strong loamy clay, &c.
- HYDRAULICS.** (Gr. Ὑδρῶν and Αὐλός, a pipe.) That branch of natural philosophy which treats of the motion of liquids, the laws by which they are regulated, and the effects which they produce. By some authors the term *hydrodynamics* is used to express the science of the motion of fluids generally, whilst the term *hydraulics* is more particularly applied to the art of conducting, raising, and confining water, and to the construction and performance of waterworks.
- HYDROSTATICS.** (Gr. Ὑδρῶν and Στασις, I stand.) The science which explains the properties of the equilibrium and pressure of liquids. It is the application of statics to the peculiar constitution of water, or other bodies, existing in the perfectly liquid form. The following is the fundamental law whereon the whole doctrine of the equilibrium and pressure of liquids is founded : when a liquid mass is in equilibrium under the action of forces of any kind, every molecule of the mass sustains an equal pressure in all directions.
- HYLMER.** See ARCHITECTS, list of, 177.
- HYPRÆTHRAL.** (Gr. Ὑπρῶ, under, and Αἰθήρ, the air.) A building or temple without a roof. The temples of this class are arranged by Vitruvius under the seventh order, which had ten columns on each front, and surrounded by a double portico as in dipteral temples. The cell was without roof, whence the name, but it generally had round it a portico of two ranges of columns, one above the other. See TEMPLE.
- HYPERBOLA.** (Gr. Ὑπερ, over, and Βάλλω, I throw.) One of the conic sections, being that made by a plane cutting the opposite side of the cone produced above the vertex, or by a plane which makes a greater angle with the base than the opposite side of the cone makes.
- HYPERBOLIC CONOID OR HYPERBOLOID.** A solid formed by the revolution of an hyperbola about its axis. See CONOID.
- HYPERBOLIC CYLINDROID.** A solid formed by the revolution of an hyperbola about its conjugate axis or line through the centre, perpendicular to the transverse axis.
- HYPERTHYRUM.** (Gr. Ὑπερ and Θύρα, a door.) The lintel or cross-piece of the aperture of a doorway.
- HYPOCAUSTUM.** (Gr. Ὑπὸ, under, and Καίω, I burn.) In ancient architecture, a vaulted apartment, from which the heat of the fire was distributed to the rooms above by means of earthen tubes. This contrivance, first used in baths, was afterwards adopted in private houses, and is supposed to have diffused an agreeable and equal temperature throughout the different rooms.
- HYPOCÆUM.** (Gr.) A term applied among the ancients to those parts of a building which were below the level of the ground.
- HYPOPODIUM.** A footstool used in the ancient baths.
- HYPOSCENIUM.** In ancient architecture, the front wall of the theatre, facing the orchestra from the stage.
- HYPOTRACHELIUM.** (Gr. Ὑπὸ, under, and Τραχήλος, the neck.) The slenderest part of the shaft of a column, being that immediately below the neck of a capital.

## I.

- ICE HOUSE.** A subterranean dépôt for preserving ice during the winter. The most important advice that can be given to the builder of an ice house is, that it be so thoroughly capable of drainage, from the lowest point of its floor, as to permit no water ever to collect upon it; this accomplished, no difficulty will, with common precaution, prevent the preservation of the ice. The aspect of such a building should be towards the south-east, that the morning sun may expel the damp air which is more prejudicial than warmth. If possible, it should be placed on a declivity for the facility of drainage. At the end of the drain which is to carry away the water arising from the melted ice, a perfect air trap should be placed, to prevent all communication between the external and internal air, from which trap the water should be carried off without the possibility of obstruction. With respect to the dimensions and form of the ice house, the former must depend on the size of the establishment, which, if very large, will require one of a medium diameter, from fifteen to twenty feet; if moderate, one from eight to fifteen feet will be large enough. The best form is the frustum of an inverted cone, ten to twenty feet deep, bricked round, and with double walls, a cavity of four inches being left between them. The ice is sustained on a grated floor, through which the water is rapidly carried off by the drainage first mentioned. The ice is best collected during the severest part of the frost, and should be pounded as laid in the ice house, besides being well rammed down as it is put in. Snow however, hard rammed, will answer when ice cannot be obtained.
- ICHOGRAPHY.** (Gr. *Ιχϋος*, a model, and *Γραφω*, I draw.) The representation of the ground plot of a building. In perspective, it is its representation, intersected by an horizontal plane at its base or groundfloor.
- ICOSAEDRON.** (Gr. *Εικοσι*, twenty, and *Ἔδρα*, seat.) One of the five regular or platonic bodies, bounded by twenty equilateral and equal triangles. It may be regarded as consisting of twenty equal and similar triangular pyramids, whose vertices all meet in the same point; and hence the content of one of these pyramids, multiplied by twenty, gives the whole content of the icosaedron.
- ICTINUS.** See ARCHITECTS, list of, 12.
- IMAGE.** In perspective, the scenographic or perspective representation of an object. See PERSPECTIVE in the body of the work, Book II. Chap. IV. Sect. 2.
- IMBOW.** (Verb.) To arch over or vault.
- IMPAGES.** A term used by Vitruvius (lib. iv. c. 6.), which has usually been considered as meaning the rails of a door.
- IMPERIAL.** (Fr.) A species of dome, whose profile is pointed towards the top, and widens towards the base, thus forming a curve of contrary flexure.
- IMPETUS.** (Lat.) In mechanics, the same with momentum or force.
- IMPLUVIUM.** (Lat.) In ancient architecture, the outer part of the court of a house which was exposed to the weather. In the summer time, it was the practice to stretch an awning over it.
- IMPOST.** (Lat. *Impono*, I lay on.) The capital of a pier or pilaster which receives an arch. It varies in the different orders; sometimes the whole of the entablature serves as the impost to an arch. The term is applicable to any supporting piece. An impost is said to be mutilated when its projection is diminished, so that it does not exceed that of the adjoining pilaster which it accompanies.
- INBOND JAMSTONE.** A bondstone laid in the joint of an aperture.
- INCERTUM.** (Lat.) A term used by Vitruvius to designate a mode of building which consisted of small rough stones and mortar, and whose face exhibited irregularly formed masonry, not laid in horizontal courses. See MASONRY.
- INCH.** A measure of length, being the twelfth part of a foot.
- INCLINATION.** (Lat.) The approach of one line, which if continued will meet another or the same of two planes.
- INCLINED PLANE.** One of the five simple mechanical powers, whose theory is deduced from the decomposition of forces. See p. 389.
- INCUSTATION.** (Lat.) Anything, such as mosaic, scagliola, &c., applied by some connecting medium to another body.
- INDEFINITE.** (Lat.) Anything which has only one extreme, whence it may be produced infinitely as it is produced from such extreme.
- INDENTED.** (Lat.) Toothed together, that is, with a projection fitted to a recess.
- INDIAN ARCHITECTURE.** See Book I. Chap. II. Sect. 6.
- INDURATION.** (Lat.) A term applied to the firmer consistence which a body acquires from various causes.
- INERTIA.** (Lat. *Iners*.) A term applied to that law of the material world which is known to predicate that all bodies are absolutely passive or indifferent to a state of rest or motion, and would continue in those states unless disturbed by the action of some extrinsic force. Inertia is one of the inherent properties of matter.

**INFINITE.** (Lat. *Infinītus*, boundless.) In geometry, that which is greater than any assignable magnitude; and as no such quantities exist in nature, the idea of an infinite quantity can only, and that most imperfectly, exist in the mind by excluding all notions of boundary or space.

**INFIRMARY.** A public building for the reception of the sick; but the term is more generally used to denote a sick-ward or building attached to some public establishment.

**INLAYING.** The art of laying on some under surface a totally different kind of work to that which the original surface would present. Thus the materials are of no consequence: in stone the inlaying may be of mosaic work or in small pieces, as in wood it may be in patterns made out by different sorts of woods, which is called *marquetry*, or by some, *parquetry*. Veneering is also a species of inlaying.

**INNER PLATE.** The wall plate, in a double-plated roof, which lies nearest the centre of the roof; the side of the other wall plate, called the *outer plate*, being nearer the outer surface of the wall.

**INNER SQUARE.** The edges forming the internal right angle of the instrument called a square.

**INSERTED COLUMN.** One that is engaged in a wall.

**INSTRUMENTS, MATHEMATICAL.** Those used for describing mathematical diagrams and drawings of every description, when the figures or elementary parts of them are composed of straight lines, circles, or portions of them. The indispensable instruments for such operations are, a *drawing pen*, a *pair of plain compasses*, commonly called *dividers*, a *pair of drawing compasses*, a *port crayon and pencil foot*, a *pair of bow, of triangular, and of proportional compasses*, a *protractor*, in the form of a semicircle or rectangle, graduated on the edges, a *plain scale*, and a *parallel rule*.

**INSULAR or INSULATED BUILDING.** Such as stands entirely detached from any other.

**INSULATED COLUMN.** One detached from a wall, so that the whole of its surface may be seen.

**INTAGLIO.** (It.) Sculpture in which the subject is hollowed out, so that the impression from it would present the appearance of a bas-relief.

**INTAVOLATA.** The same as *CYMATIUM*, which see.

**INTERCEPTED AXIS.** In conic sections, that part of the diameter of a curve comprehended between the vertex and the ordinate. It is also called the *abscissa*, and forms an arch of a peculiar kind.

**INTERCOLUMNIATION.** (Lat. *Inter*, between, and *Columna*, a column.) The distance between two columns measured at the lower part of their shafts. It is one of the most important elements in architecture, and on it depends the effect of the columns themselves, their pleasing proportion, and the harmony of an edifice. Intercolumniations are of five species, *pycnostylos*, *systylos*, *diastylos*, *araestylos*, and *eustylos*, under which several terms each is defined. The subject is also found more largely treated of in Book III. Chap. I. Sect. 9.

**INTERDENTELS.** The space between two dentels. From a comparison of various examples, it seems that the Greeks placed their dentels wider apart than the Romans. In the temple of Bacchus at Teos, the interdental is two-thirds the breadth of the dentel, and in that of Minerva Polias at Priene, the interdental is nearly three-fourths. In the temple of Jupiter Stator at Rome, the interdentels are equal to half the breadth of the dentel.

**INTERIOR ANGLE.** An angle formed within any figure by two straight lined parts of the perimeter or boundary of the figure, the exterior angle being that which is formed in producing a side of the perimeter of the figure. The term is also applied to the two angles formed by two parallel lines, when cut on each side of the intersecting line.

**INTERIOR AND OPPOSITE ANGLES.** An expression applied to the two angles formed by a line cutting two parallels.

**INTERJOIST.** The space or interval between two joists.

**INTERMODILLION.** The space between two modillions.

**INTERNAL ANGLE.** See **INTERIOR ANGLE**.

**INTERPILASTER.** The space between two pilasters.

**INTERQUARTER.** The interval between two quarters.

**INTERTIES.** Short pieces of timber used in roofing to bind upright posts together, in roofs, partitions, in lath and plaster work, and in walls with timber framework.

**INTRADOS.** The interior and lower line or curve of an arch. The exterior or upper curve is called the *extrados*. See **ARCH**.

**INVENTION.** (Lat. *Invenio*, I find.) In the fine arts, the choice and production of such objects as are proper to enter into the composition of a work of art. "Strictly speaking," says Sir Joshua Reynolds, "invention is little more than a new combination of those images which have been previously gathered and deposited in the memory: nothing can come of nothing: he who has laid up no materials can produce no combinations." Though there be nothing new under the sun, yet novelty in art will be attainable till all the combinations of the same things are exhausted, a circumstance that can never come to pass.

**INVERTED ARCH.** One wherein the lowest stone or brick is the key-stone. It is used in foundations, to distribute the weight of particular points over the whole extent of the

foundation, and hence its employment is frequently of the first importance in constructive architecture.

**INVOLUTE.** See **EVOLUTE**.

**INWARD ANGLE.** The re-entrant angle of a solid. See **INTERNAL ANGLE**.

**IONIC ORDER.** See Book III. Chap. I. Sect. 5.

**IRON.** See Book II. Chap. II. Sect. 5.

**IRONMONGERY.** See Book II. Chap. III. Sect. 10.

**IRREGULAR FIGURE.** One whose sides, and consequently angles, are unequal to each other.

**ISAGON.** (Gr. *isos*, equal, and *γωνία*, an angle.) A figure with equal angles.

**ISEMBERT.** See **ARCHITECTS**, list of, 105.

**ISIDORUS.** See **ARCHITECTS**, list of, 62.

**ISIDORUS OF BYZANTIUM.** See **ARCHITECTS**, list of, 64.

**ISODOMUM.** (Gr.) One of the methods of building walls practised by the Greeks. It was executed in courses of equal thickness, and with stones of equal lengths. The other method, called *pseudisodomum*, in which the heights, thicknesses, and lengths of the stone were different. There was another mode called **EMPLECTON**, which see.

**ISOSCELES TRIANGLE.** One in which two of the sides are of equal length.

**IVARA.** See **ARCHITECTS**, list of, 220.

## J.

**JACK ARCH.** One whose thickness is only of one brick.

**JACK PLANE.** A plane about eighteen inches long, used in taking off the rough surface left by the saw or that of the axe, and of taking off large protuberant parts, to prepare the stuff for the trying plane.

**JACK RAFTER.** See **HIP ROOF**.

**JACK RIBS.** Those in a groin, or in a polygonally-domed ceiling, that are fixed upon the hips.

**JACK TIMBER.** Any one interrupted in its length, or cut short.

**JAMB LININGS.** The two vertical linings of a doorway which are usually of wood.

**JAMB POSTS.** Those introduced on the side of a door, to which the jamb linings are fixed. They are particularly used when partitions are of wood.

**JAMB STONES.** In stone walls are those which are employed in building the sides of apertures, in which every alternate stone should go entirely through the thickness of the wall.

**JAMBS.** (Fr.) The sides of an aperture which connect the two sides of a wall. See **APERTURE** and **CHIMNEY**.

**JAMES, JOHN.** See **ARCHITECTS**, list of, 228.

**JEAN D'ECHELLES.** See **ARCHITECTS**, list of, 115.

**JERKIN HEAD.** The end of a roof not hipped down to the level of the opposite adjoining walls, the gable being carried higher than the level of those walls.

**JIB DOOR.** A door so constructed as to have the same continuity of surface with that of the partition or wall in which it stands. Its use is to preserve an unbroken surface in an apartment where one door only is wanted nearer to one end of a room than another, and generally for the purpose of preserving uniformity.

**JOGGLE.** The joint of two bodies so constructed as to prevent them sliding past each other, by the application of a force in a direction perpendicular to the two pressures by which they are held together. Thus the struts of a roof are joggled into the truss posts and into the rafters. When confined by mortise and tenon, the pressure which keeps them together is that of the rafter and the reaction of the truss post. The term is also used in masonry to signify the indentation made in one stone to receive the projection in another, so as to prevent all sliding on the joints. This may be also accomplished by means of independent pieces of material let into the adjacent stones.

**JOGGLE PIECE.** The truss post in a roof when formed to receive a brace or strut with a joggle.

**JOHANNES OF MILETUS.** See **ARCHITECTS**, list of, 65.

**JOHN OF PADUA.** See **ARCHITECTS**, list of, 187.

**JOINER.** The artisan who joins wood by glue, framing, or nails, for the finishings of a building.

**JOINERY.** The practice of framing or joining wood for the internal and external finishings of houses; thus the covering and lining of rough walls, the covering of rough timbers, the manufacture of doors, shutters, sashes, stairs, and the like, are classed under the head of joinery. See Book II. Chap. III. Sect. 6.

**JOINT.** The surface of separation between two bodies brought into contact and held firmly together, either by some cementing medium, or by the weight of one body lying on another. A joint, however, is not merely the contact of two surfaces, though the nearer they approach the more perfect the joint. In masonry, the distances of the planes intended to form the joint is comparatively considerable, because of the coarseness of the particles which enter into the composition of the cement.

- JOINER.** In *joinery* is the largest plane used by the joiner in straightening the face of the edge of the stuff to be prepared. In *bricklaying*, it is a crooked piece of iron forming two curves of contrary flexure by its edges on each side, and is used for drawing, by the aid of the jointing rule, the  *coursing*  and  *vertical*  joints of the work.
- JOINTING RULE.** A straight edge used by bricklayers for the regulation of the direction and course of the jointer in the horizontal and vertical joints of brickwork.
- JOISTS.** (Fr. *Joindre*.) The timbers whereto the boards of a floor or the laths for a ceiling are nailed. They rest on the walls or on girders; sometimes on both. When only one tier of joists is used, the assemblage is called *single-flooring*; when two, *double-flooring*.
- JONES, INIGO.** See ARCHITECTS, list of, 252.
- JUFFERS.** An obsolete term for pieces of timber four or five inches square.
- JUMP.** An abrupt rise in a level course of brickwork or masonry to accommodate the work to the inequality of the ground. Also in *quarrying*, one among the various names given to the dislocations of the strata in quarries.
- JUMPER.** A long iron chisel used by masons and miners.

## K.

- KEEP or KEEP TOWER.** A term almost synonymous with *donjon*. See CASTLE.
- KENDALL.** See ARCHITECTS, list of, 166.
- KENT.** See ARCHITECTS, list of, 282.
- KERF.** The way made by a saw through a piece of timber, by displacing the wood with the teeth of the saw.
- KEY.** (Sax. *Cæge*.) An instrument for driving back the bolt of a lock. The *key of a floor* is the board last laid down. In joinery generally a key is a piece of wood let into the back of another in the contrary direction of the grain, to preserve the last from warping.
- KEY STONE.** The highest central stone of an arch. See ARCH.
- KEYED DADO.** That which has bars of wood grooved into it across the grain at the back to prevent its warping.
- KEYES.** See ARCHITECTS, list of, 151.
- KEYS.** In naked flooring are pieces of timber fixed in between the joists by mortise and tenon. When these are fastened with their ends projecting against the sides of the joists, they are called *strutting-pieces*.
- KILDERKIN.** A measure containing eighteen gallons of beer, and sixteen ale measure.
- KILN.** A building for the accumulation and retention of heat in order to dry or burn certain materials deposited within them.
- KING POST.** The centre post in a trussed roof. See CROWN POST.
- KIRB PLATE.** See CURB PLATE.
- KIRB ROOF.** See CURB ROOF.
- KITCHEN.** (Fr. *Cuisine*.) The apartment or office of a house wherein the operations of cookery are carried on.
- KNEE.** A part of the back of a handrailing, of a convex form, being the reverse of a *ramp*, which is also the back of a handrail, but is concave. The term knee is also given to any small piece of timber of a bent or angular form.
- KNEE PIECE or KNEE RAFTER.** An angular piece of timber, to which other pieces in the roof are fastened.
- KNOTTING.** The preliminary process in painting, to prevent the knots appearing, by covering them with a coat composed of red lead, then white lead and oil, and lastly, a coat of gold size. Sometimes leaf silver is also used.
- KNUCKLE.** The joint of a cylindrical form, with a pin as an axis, by which the straps of a hinge are fastened together.

## L.

- LAERL.** In Gothic architecture, the drip or hood moulding over an aperture when it is returned square.
- LABELYE.** See ARCHITECTS, list of, 285.
- LABOUR.** (Lat.) A term in masonry employed to denote the value of a piece of work in consideration of the time bestowed upon it.
- LABYRINTH.** (Gr. *Λαβυρινθος*.) Literally a place, usually subterranean, full of inextricable windings. The four celebrated labyrinths of antiquity were the Cretan, Egyptian, Lemnian, and Italian. The first has the reputation of being the work of Dædalus to secure the Minotaur; the second is said to have been constructed under the command of Psammeticus, king of Egypt; the third was on the island of Lemnos, and was supported by columns of great beauty; the fourth is reported to have been designed by Porsenna, king of Etruria, as a tomb for himself and his successors.
- LABYRINTH FRET.** A fret, with many turnings, in the form of a labyrinth. See FRET.

**LACER.** See ARCHITECTS, list of, 48.

**LACONICUM.** (Lat.) One of the apartments in the ancient baths, so called from its having been first used in Laconia.

**LACQUEE.** A yellow varnish, consisting of a solution of shell-lac in alcohol, coloured by gamboge, saffron, annatto, or other yellow, orange, or red colouring matters. The use of lacquer is chiefly for varnishing brass, and some other metals, in order to give them a golden colour and preserve their lustre.

**LACTARIUM.** (Lat.) Strictly a dairy-house. In ancient architecture, it was a place in the Roman herb market, indicated by a column, called the *Columna Lactaria*, where foundlings were fed and nourished.

**LACUNAR.** (Lat.) The ceiling or under surface of the member of an order. Also the under side of the *larmier* or *corona* of a cornice. The under side also of that part of the architrave between the capitals of columns. The ceiling of any part in architecture receives the name of *lacunar* only when it consists of compartments sunk or hollowed, without spaces or bands, between the panels; if it is with bands, it is called *laquear*.

**LADY CHAPEL.** The name given to a small chapel dedicated to the Virgin, generally, in ancient cathedrals, placed behind the high altar.

**LANCET ARCH.** One whose head is shaped like the point of a lancet, and generally applied to long narrow windows.

**LANDING.** The terminating floor of a flight of stairs, either above or below it.

**LANFRANC.** See ARCHITECTS, list of, 81.

**LANFRANI.** See ARCHITECTS, list of, 139.

**LANGHANS.** See ARCHITECTS, list of, 310.

**LANTERN.** (Fr. *Lanterne*.) A drum-shaped erection, either square, circular, elliptical, or polygonal, on the top of a dome, or on that of an apartment, to give light.

**LAP.** The part of one body which lies on and covers another.

**LAPO.** See ARCHITECTS, list of, 120.

**LAQUEAR.** See LACUNAR.

**LARARIUM.** (Lat.) In ancient architecture, the apartment in which the lares or household gods were deposited. It frequently contained also statues of the proprietor's ancestors.

**LARDER.** The place in which undressed meat is kept for the use of a family.

**LARMIER.** (Fr.) The same as *CORONA*, which see.

**LATCH.** The catch by which a door is held fast.

**LATENT HEAT.** That which is insensible to the thermometer, upon which the liquid and aeriform states of bodies depend, and which becomes sensible during the conversion of vapours into liquids and of liquids into solids.

**LATH.** (Sax. *Lætca*.) A thin cleft piece of wood used in slating, tiling, and plastering. There are two sorts, double and single, the latter being about three-eighths of an inch thick, and the former barely a quarter of an inch. *Pantile laths* are long square pieces of fir, on which the pantiles hang.

**LATH BRICKS.** A species made in some parts of England. They are twenty-two inches long and six inches broad.

**LATH FLOATED AND SET FAIR.** Three-coat plasterers' work, in which the first is called *pricking up*; the second *floating*; the third, or finishing, is done with fine stuff.

**LATH LAID AND SET.** Two-coat plasterers' work, except that the first is called *laying*, and is executed without *scratching*, unless with a broom. When used on walls, this sort of work is generally coloured; when on ceilings, whited.

**LATH PLASTERED, SET, AND COLOURED.** The same as lath laid, set, and coloured.

**LATH PRICKED UP, FLOATED, AND SET FOR PAPER.** The same as *lath floated and set fair*.

**LATERAL STRENGTH.** The resistance which a body will afford at right angles to its grain.

**LATTICE.** (Fr. *Lattis*.) A reticulated window, made of laths or strips of iron, separated by glass windows, and only used where air, rather than light, is to be admitted, as in cellars and dairies.

**LAUNDRY.** An apartment occupied by the laundress of an establishment. It should be spacious and well supplied with every convenience for mangling, drying, and ironing the linen of a family. *Horses*, or slender frames of wood, should be provided for hanging the linen upon, which should be suspended to the timbers of the ceiling by pulleys, by which they may be raised and lowered.

**LAVATORY.** (Lat.) See CLOISTER.

**LAYER.** In brickwork and masonry, synonymous with *COURSE*, which see.

**LAYING.** In plastering, the first coat on lath of two-coat work, the surface whereof is roughed by sweeping with a broom. The difference between *laying* and *rendering* being, that the latter is the first coat upon brick.

**LAZARHOUSE or LAZARETTO.** (Ital.) A hospital for the reception of the poor and those afflicted with contagious diseases. There are many in the southern states of Europe for the performance of quarantine, into which those only are admitted who arrive from

countries infected by the plague, or suspected of being so. An account of the principal lazarettoes of Europe was published by the celebrated Howard.

**LEAD.** (Sax. *Læb.*) The heaviest metal next to gold, platina, and mercury, being eleven times heavier than its own bulk of water. See Book II. Chap. II. Sect. 6.

**LEANTO.** A building whose rafters pitch against or lean on to another building or against a wall.

**LEAVES.** (Sax. *Læaf.*) Ornaments imitated from natural leaves, whereof the ancients used two sorts, natural and imaginary. The former were those of the laurel, palm, acanthus, and olive; but they took great liberties in the representations of all of them.

**LEDGE.** A surface serving to support a body either in motion or at rest. Ledges of doors are the narrow surfaces wrought upon the jambs and soffits parallel to the wall to stop the door, so that when it is shut the ledges coincide with the surface of the door. A ledge, therefore, is one of the sides of a *rebate*, each rebate being formed of two sides. In temporary work the ledges of doors are formed by fillets. Also the horizontal planks in common doors, to which the vertical planks are nailed. See Book II. Chap. III. Sect. 5.

**LEDGEMENT.** The development of a surface, or the surface of a body stretched out on a plane, so that the dimensions of the different sides may be easily ascertained.

**LEDGERS.** In scaffolding for brick buildings are horizontal pieces of timber parallel to the walls. They are fastened to the *standards*, or upright poles, by cords, to support the *put-logs*, which lie at right angles to and on the walls as they are brought up, and receive the boards for working on.

**LEDoux.** See ARCHITECTS, list of, 306.

**LEGRAND.** See ARCHITECTS, list of, 309.

**LEGS OF AN HYPERBOLA.** The two parts on each side the vertex.

**LEGS OF A TRIANGLE.** The sides which inclose the base.

**LENGTH.** (Sax. *Leug.*) The greatest extension of a body. In a right prism the length is the distance between the ends; in a right pyramid or cone, the length is the distance between the vertex and the base.

**LENGTHENING OF TIMBER** is the method of joining several beams, so as to form a long beam of any given length.

**LEONI.** See ARCHITECTS, list of, 279.

**LESCOT.** See ARCHITECTS, list of, 237.

**LEVEL.** (Sax. *Læfel.*) A line or surface which inclines to neither side. The term is used substantively to denote an instrument which shows the direction of a straight line parallel to the plane of the horizon. The plane of the sensible horizon is indicated in two ways: by the direction of the plummet, or plumb line, to which it is perpendicular; and by the surface of a fluid at rest. Accordingly, levels are formed either by means of the plumb line, or by the agency of a fluid applied in some particular manner. They all depend, however, upon the same principle, namely, the action of terrestrial gravity.

The carpenter's level consists of a long rule, straight on its lower edge, about ten or twelve feet in length, with an upright fixed to its upper edge, perpendicular to and in the middle of the length, having its sides in the same plane with those of the rule, and a straight line drawn on one of its sides perpendicular to the straight edge of the rule. This standing piece is generally mortised into the other, and finally braced on each side, to secure it from accident, and has its upper end kerfed in three places, viz. through the perpendicular line, and on each side. The straight edge of the transverse piece has a hole, or notch, cut out on the other side equal on each side the perpendicular line. A plummet is suspended by a string from the middle kerf, at the top of the standing piece, to vibrate freely in the hole or notch when hanging at full length. When the straight edge of the level is applied to two distant points, with its two sides placed vertically, if the plummet hangs freely, and the string coincides with the straight line on the standing piece, the two points are level. If not, suppose one of the points to be at the given height, the other must be lowered or raised, as the case may require, till the string is brought to a coincidence with the perpendicular line. By two points is meant two surfaces of contact, as two blocks of wood, or the upper edges of two distant beams.

The uses of the level in carpentry are various, and need not be here detailed. The *mason's level* is formed of three pieces of wood, joined in the form of an isosceles triangle, having a plummet suspended from the vertex over a mark in the centre of the base.

**LEVELLING.** The art or act of finding a line parallel to the horizon, at one or more stations, in order to determine the height of one place with respect to another, for laying grounds even, regulating descents, draining morasses, conducting waters for the irrigation of land, &c. See ADDENDA.

**LEVER.** In mechanics an inflexible rod, moveable about a fulcrum, or prop, and having forces applied to two or more points in it. The lever is one of the mechanical powers, and being the simplest of them all, was the first attempted to be explained. For its properties see Book II. Chap. I. Sect. 8.

**LEVER BOARDS.** A set of boards so fastened that they may be turned at any angle to

- admit more or less light, or to lap upon each other so as to exclude all air or light through apertures.
- LEWIS or LEWISSON.** An instrument said to have been used in England by the builders of the middle ages to raise stones of more than ordinary weight to the upper part of a building. It was revived by a French artisan in the reign of Lewis XIV., and is now generally employed. It operates by the pieces forming its dove-tail end being kept in their correspondent places in the stone by a middle straight piece, kept in its situation by a pin passing through it and the dovetail pieces at top, and the combination of the whole, is with a large ring.
- LIAS.** A provincial name adopted by geologists for an argillaceous limestone, which, together with its associated bed, is characterised by peculiar fossils.
- LIBON.** See ARCHITECTS, list of, 11.
- LIBRARY.** An edifice or apartment for the reception of a collection of books. For remarks on the construction of public libraries see Book III. Chap. III. Sect. 9.
- LIGHTS.** A term sometimes used to denote the openings of doors, gates, and windows, and other places through which air and light have passage.
- LIGHTHOUSE.** A lofty building, on the top whereof artificial lights are placed to guide ships at sea. For general observations on lighthouses see Book III. Chap. III. Sect. 12.
- LIKE ARCS.** In the projection of the sphere, the parts of lesser circles containing an equal number of degrees with the corresponding arcs of greater circles.
- LIKE FIGURES.** In geometry, such as have their angles equal, and the sides about the equal angles proportional.
- LIKE SOLIDS.** Those which are contained under like planes.
- LIME.** (Germ. Leim, glue.) A most useful earth, obtained by exposing chalk, and other kinds of limestones or carbonates of lime, to a red heat, an operation generally conducted in kilns constructed for the purpose, by which the carbonic acid is expelled, and lime, more or less pure, according to the original quality of the limestone, remains, in which state it is called *quicklime*. See Book II. Chap. II. Sect. 10.
- LIMEKILN.** One for the purpose of burning lime. They are constructed in a variety of ways, to save expense, or to answer to the particular nature of the fuel.
- LIMESTONE.** A generic term for those varieties of carbonate of lime which are neither crystalline or earthy, the former being calcareous spar, the latter chalk. When burned they yield quicklime.
- LINE.** (Lat. Linea.) In geometry, a magnitude having only one dimension, and defined by Euclid to be that which has length without breadth. The term is also used to denote a measure of length used formerly in France, namely, the twelfth part of an inch, or  $\frac{1}{12}$  of a foot.
- LINE OF DIRECTION.** In mechanics, the line in which motion is communicated.
- LINE, GEOMETRICAL.** In perspective, any straight line in the geometrical or primary line.
- LINE, HORIZONTAL.** A line parallel to the horizon. In perspective, it is the vanishing line of horizontal planes.
- LINE OF STATION.** The intersection of a plane passing through the eye, perpendicular to the picture, and to the geometrical or primary plane with the plane itself.
- LINE, VERTICAL.** The intersection of a vertical plane with the picture passing along the station line.
- LINE, VISUAL.** A ray of light reflected from the object to the eye.
- LINES OF LIGHT AND SHADE.** Those in which the light and shade of a body are separated. Thus, on a curved surface, it is the line determined by a tangent to the surface in the direction of the rays of light.
- LINEAR PERSPECTIVE.** See Book II. Chap. IV. Sect. 2.
- LINING.** The covering of the surface of any body with another thin substance. Thus the lining of a wall is a wooden boarding, whose edges are either rebated or grooved and tongued. Lining is distinguished from *casing*, the first being a covering in the interior of a building, whilst the latter is the covering of the exterior part of a building.
- LINING OUT STUFF.** (Participle.) The drawing lines on a piece of board or plank so as to cut it into thinner pieces.
- LININGS of BOXINGS for window shutters,** are the pieces of framework into which the window shutters are folded back.
- LININGS of a DOOR.** Those of the sides of apertures of doors called the jambs or jamb-linings, that which covers the top or head being the soffit.
- LINTEL.** (Span.) A horizontal piece of timber or stone over a door, window, or other opening to discharge the superincumbent weight. If a wall be very thick, more than one lintel piece will be required, unless scanting of sufficient width be found. In some old books on carpentry lintels are classed under wall plates, but the word is now never used in this sense, unless the joisting or tie-beams rest upon it, in which case it is both a lintel and a wall plate.
- LIST or LISTEL.** The same as FILLER, which see.

LISTED BOARDS. See BOARDS.

LISTING. (Participle.) Cutting the sap wood out from both edges of a board.

LOAM. A soil in which clay prevails. It is called heavy or light as the clay may be more or less abundant.

LOBBY. (Germ. Laube.) An inclosed space surrounding or communicating with one or more apartments, such as the boxes of a theatre, for instance. By it also is understood a small hall or waiting room, or the entrance into a principal apartment where there is a considerable space between it and a portico or vestibule; but the dimensions, especially as regards the width, will not allow of its being called a vestibule or anti-room.

LOCK. (Sax. Loc.) A well-known instrument, consisting of springs and bolts, for fastening doors, drawers, chests, &c. A good lock is a masterpiece in smithery, requiring much art and delicacy to contrive and vary the wards, springs, bolts, and other parts whereof it is composed, so as to adjust them to the places where they are serviceable, and to the various purposes of their use. The structure of locks is so varied, and the number of inventions of their different sorts so extended, that we cannot attempt to enumerate them.

Those placed on outer doors are called *stock locks*, those on chamber doors *spring locks*, and such as are hidden in the thickness of the doors to which they are applied, *mortise locks*. The padlock is too well known to need description here.

The conditions which seem indispensable in a perfect lock are, 1. that certain parts of the lock should be variable in position through a great number of combinations, one only whereof shall allow the lock to be opened or shut; 2. that this last-mentioned combination should be variable at the pleasure of the possessor; 3. that it should not be possible, after the lock is closed and the combination disturbed, for any one, not even the maker of the lock, to discover, by any examination, what may be the proper situations of the parts required to open the lock; 4. that trials of this kind shall not be capable of injuring the works; 5. that it shall require no key; 6. and be as easily opened in the dark as in the light; 7. that the opening and shutting shall be done by a process as simple as that of a common lock; 8. that it should open *without* a key or *with* one, at pleasure; 9. that the keyhole be concealed, defended, or inaccessible; 10. that the key may be used by a stranger without his knowing or being able to discover the adopted combination; 11. that the key be capable of adjustment to all the variations of the lock, and yet be simple; 12. that the lock should not be liable to be taken off and examined, whether the receptacle be open or shut, except by one who knows the method of combination.

The above considerations involve a problem of great mechanical difficulty, which has not yet been solved, though much has been done towards it. For the locks in common use in buildings, see p. 592.

LODGE. A small house, situate in a park or domain, subordinate to the mansion. Also the cottage placed at the gate of the road leading to the mansion.

LOGARITHMS. See p. 246, *et seq.*

LOGHOUSE. A hut constructed of the trunks of trees.

LOGISTIC SPIRAL. One whose radii are in continued proportion, and in which the radii are at equal angles; or, in other words, a spiral line whose radii every where make equal angles with the tangents.

LOMBARDO, M. See ARCHITECTS, list of, 174.

LOMBARDO, P. See ARCHITECTS, list of, 173.

LOMBARDO, SANTE. See ARCHITECTS, list of, 216.

LONGIMETRY. A term used to denote the operation of trigonometry for measuring lengths, whether accessible or inaccessible.

LOOP. (Fr.) A small narrow window. A *loophole* is a term applied to the vertical series of doors in a warehouse, from which the goods, in craning, are delivered into a warehouse.

LOREZ, PHILIP DE. See ARCHITECTS, list of, 214.

LORUS. A plant of the water-lily species much used in the architectural ornaments of the early nations, and especially in the capitals of Egyptian columns.

LOUIS. See ARCHITECTS, list of, 304.

LOZENGE. A quadrilateral figure of four equal sides, with oblique angles.

LUFFER BOARDINGS. (Fr. Louvre.) See BOARDING LUFFER.

LUNE or LUNULA. The space between two equal arcs of a circle.

LUNETTE. (Fr.) A cylindric, cylindroidic, or spherical aperture in a ceiling. As an example of the term, we may refer to the upper lights in the nave of St. Paul's Cathedral.

LUSARCHE. See ARCHITECTS, list of, 110.

LUTHERN. The same as DORMER, which see.

LYING PANELS. Those wherein the fibres of the wood, or the grain of it, lie in an horizontal direction.

LYSIS. (Gr.) A plinth or step above the cornice of the podium of ancient temples, which surrounded or embraced the stylobate, whereof an example may be seen in the temple of Fortuna Virilis at Rome.

## M.

**M ROOF.** A roof formed by the junction of two common roofs with a vallum between them. The letter **M** inverted represents this species of covering.

**MACHICOLATIONS.** (Fr. *Machicoulis*.) In castellated architecture are, according to Grose, the projections, supported by brackets or corbels, through which melted lead and stones were dropped on the heads of assailants. They were not probably, however, projecting works, but sometimes were considered as the series of square holes in the vaultings of the portals used for the same purpose.

**MACHINE.** (Gr. *Μαχῆνη*.) In a general sense, any thing which serves to increase or regulate the effect of a given force. Machines are *simple* or *compound*. The former are the simple mechanical powers, six in number; viz. the lever, the wheel and axle, the pulley, the wedge, the screw, and the funicular machine. The latter are formed by the combination of two or more simple machines, and are classed according to the forces by which they are put in motion, as *hydraulic machines*, *pneumatic machines*, *electrical machines*, &c., or the purposes they are intended to serve, as *military machines*, *architectural machines*, &c.

**MACHUCA.** See **ARCHITECTS**, list of, 227.

**MADERNO.** See **ARCHITECTS**, list of, 249.

**MAGLIONE.** See **ARCHITECTS**, list of, 123.

**MAGNESIAN LIMESTONE.** An extensive series of beds lying in geological position immediately above the coal measures; so called because the *limestone*, which is the principal member of the series, contains *magnesia*.

**MAGNITUDE.** (Lat.) A term by which size, extent, or quantity is designated. It was originally applied to the space occupied by any figure; or, in other words, it was applied to objects strictly termed geometrical, and of three dimensions, length, breadth, and thickness, but it has gradually become enlarged in its signification, so as to be given to every kind of quantity that admits of mensuration, or of which greater or less can be predicated; in which sense it was used by Euclid.

**MAHOGANY.** A wood often used for doors and window-sashes. See p. 487. The Jamaica mahogany is the hardest and most beautiful, and is distinguished from that of Honduras by the chalky appearance of its fibres. Those from Honduras appear quite dark. After oiling, this distinction is not so clearly observable.

**MAIN COUPLE.** See **COUPLE**.

**MAJANO.** See **ARCHITECTS**, list of, 149.

**MALLEABILITY.** (Lat. *Malleus*, a hammer.) The property of being susceptible of extension under the blows of a hammer. It is a characteristic of some of the metals, most particularly in gold. Common gold-leaf is not more a two-hundred-thousandth part of an inch in thickness. Five grains may be beaten out so as to cover a surface of more than two hundred and seventy square inches.

**MALLET.** (Lat.) A large kind of wooden hammer much used by artificers who work with a chisel, as masons, stonecutters, carpenters, joiners, &c.

**MALTHA.** (Gr.) A native bitumen used by the ancients for plastering the walls of their dwellings, &c. An artificial kind was made of pitch, wax, plaster, and grease; another sort was composed of lime slaked with wine, and incorporated with melted pitch and fresh figs.

**MANDREL.** (Fr. *Mandrin*.) In machinery, a revolving shank, to which turners affix their work in the lathe.

**MANDROCKLES.** See **ARCHITECTS**, list of, 6.

**MANGER.** The trough in the stall of a stable wherein is placed the corn or other short food given to live stock, and more especially to horses.

**MANLIO.** See **ARCHITECTS**, list of, 203.

**MANSARD.** See **ARCHITECTS**, list of, 258.

**MANSARD, JULES HARDOUIN.** See **ARCHITECTS**, list of, 267.

**MANSARD ROOF.** (So called from the name of its inventor, François Mansard.) The same as **CURB ROOF**, which see.

**MANSION.** A large house; a term more usually applied to one in the country. The origin of the word and its application is supposed to be derived from the *mansiones*, or stationary camps of the Roman soldiers.

**MANTLE TREE.** See **CHIMNEY**.

**MARBLE.** (Fr. *Marbre*.) A term limited by mineralogists and geologists to the several varieties of carbonate of lime, having more or less of a granular and crystalline texture. Among sculptors, the word is used to denote several compact or granular kinds of stone susceptible of a very fine polish; the varieties of it are extremely numerous. The most valuable sorts used by the ancients were the *Pentelican*, which was white, and was obtained from Mount Penteles in Attica. It was used in the Parthenon and other Athenian buildings, and was also in great repute among the sculptors. The *Parian marble* was, as its name imports, from the island of Paros, in which Mount Marpeessus yielded the best, which was called *Marpessian*. The marble of Paros was also sometimes termed

*Lychnus*, because of its use in making candelabra, and *Lygdinum*, from the promontory of Lygdos. Another of the white marbles of antiquity was that of Mount Hymettus in Attica. The marbles of *Thasus* and *Lesbos* were white, and in great repute. The latter island produced also a black marble. At *Luna*, in Etruria, there was found a marble even whiter than that of Paros. Amongst the white marbles may, moreover, be mentioned the *marmor Phellense* from Mount Phellens; the *marmor Coraliticum*, found near the river Coralios in Phrygia, and termed also *Sangarium*, from another name of the same river. The *marmor Cyzicum* was taken from the quarries of Cyzicus in Asia Minor; the *Synnadicum*, or *marmor Phrygium*, was obtained from the environs of the city of Synnas in Phrygia, and was of a black ground with small circles. Another sort of marble, which resembled ivory in its colour, was called *chernites*. The marble of *Tenarus* was highly esteemed as a black marble. The *marmor Lybicum*, or *Numidian marble*, called also *marmor Luculleum*, was what the French term *noir antique*. The celebrated *marmor Chium* was excavated from the Mount Pelicinus in the island of Chio, and was of a transparent chequered black colour. The *marmor obsidianum* was from Ethiopia, and of the black species, as was the *Proconnesian*, or *Cyzican marble*, from the island of Proconnesus. That from Mount Taygetes, called *marmor Laconicum*, was the well-known *verd antique* of antiquaries. The marble of *Carystus* was a mingled green; that called the *Atracium*, from Mount Atrax in Thessaly, was a mixture of white, green, blue, and black. The green *Tiberian* and *Augustan* marbles were obtained from Egypt. The *marmor Ophites*, or *Memphites*, which took its first name from its resemblance to the skin of a serpent, and its second from the city of Memphis, where it was found, is the *Serpentino antico* of the Italians. The marble of *Corinth* was yellow, and the *marmor Phengites* of Cappadocia was white, with yellow spots. The *Rhodian marble* was marked with spots resembling gold; that of *Melos* was yellow, and excavated in Mount Acynthus. The varieties of marble used in modern times are exceedingly numerous, and a classification of them would occupy a larger space than can be here given. Except the finest specimens of white marble, they are mostly opaque. Some extremely fine specimens of white marble are to be seen in the Borghese Palace at Rome, which, on being suspended by the centre on a hard body, bend very considerably. It is found that statuary marble exposed to the sun acquires, in time, this property, thus indicating a less degree of adhesion of its parts than it naturally possessed.

Almost every mountainous district of the world produces this mineral, but the finest and most valuable is from Italy. See Book II. Chap. II. Sect. 3.

**MARBLE, POLISHING OF.** The material is brought to an even face by rubbing with free-stone, afterwards with pumice-stone, and lastly with emery of several colours; but white marble is finished with calcined tin. The Italians polish with lead and emery. The sawing of marble, preparatory to polishing, is by a saw of soft iron, with a continued supply of the sharpest sand and water.

**MARGIN OF A COURSE.** That part of the upper side of a course of slates which appears uncovered by the next superior course.

**MARGOLD WINDOW.** See ROSE WINDOW.

**MARMORATUM.** (Lat.) A cement used by the ancients, formed of pounded marble and lime well beaten together.

**MARQUETRY OF PARQUETRY.** (Fr. Marquetry.) Inlaid work, consisting of different pieces of various coloured woods, of small thickness, glued on to a ground, usually of oak or fir well dried and seasoned, which, to prevent casting and warping, is composed of several thicknesses. It was used by the early Italian builders in cabinet work; and John of Vienna, and others of his period, represented by its means figures and landscapes; but in the present day it is chiefly confined to floors, in which the divers pieces of wood are usually disposed in regular geometrical figures, and are rarely of more than three or four species.

**MASCAL OR MARSHALL.** See ARCHITECTS, list of, 220.

**MASONRY.** (Fr.) The science of combining and joining stones for the formation of walls and other parts in constructing buildings. When applied in the construction of domes, groins, and circular arches, it is difficult and complicated, and is dependent on a thorough knowledge of descriptive geometry. The subject is treated in the body of this work, Book II. Chap. III. Sect. 3.

Among the ancients, several sorts of masonry were in use, which are described by Vitruvius as follows, in the eighth chapter of his second book:—"The different species of walls," he observes, "are the *reticulatum* (net-like) (fig. 1045. A), a method now in general use, and the *incertum* (B), which is the ancient mode. The *reticulatum* is very beautiful, but liable to split, from the beds of the stones being unstable, and its deficiency in respect of bond. The *incertum*, on the contrary, course over course, and the whole bonded together, does not present so beautiful an appearance, though stronger than the *reticulatum*. Both species should be built of the smallest sized stones, that the walls, by sucking up and attaching themselves to the mortar, may last the longer: for as the stones are of a soft and porous nature, they absorb, in dry-

ing, the moisture of the mortar ; and this, if used plentifully, will consequently exercise a greater cementing power ; because from their containing a larger portion of moisture, the wall will not, of course, dry so soon as otherwise ; and as soon as the moisture is absorbed by the pores of the stones from the mortar, the lime, losing its power, leaves the sand, so that the stones no longer adhere to it, and in a short time the work becomes unsound. We may see this in several monuments about the city (Rome) which have been built of marble, or of stones squared externally, that is, on one face, but filled up with rubble run with mortar. Time in these has taken up the moisture of the mortar, and destroyed its efficacy by the porosity of the surface on which it acted. All cohesion is thus ruined, and the walls fall to decay. He

who is desirous that this may not happen to his work should build his two-face walls two feet thick, either of red stone, or of bricks, or of common flint, binding them together with iron cramps run with lead, and duly preserving the middle space or cavity. The materials in this case not being thrown in at random, but the work well brought up on the beds, the upright joints properly arranged, and the face-walls, moreover, regularly tied together, they are not liable to bulge, nor be otherwise disfigured. In these respects one cannot refrain from admiring the walls of the Greeks. They make no use of soft stone in their buildings ; when, however, they do not employ squared stones, they use either flint or hard stone, and, as though building with brick, they cross or break the upright joints, and thus produce the most durable work. There are two sorts of this species of work, one called *isodomum* (CC), the other *pseudisodomum* (DD). The first is so called, because in it all the courses are of an equal height ; the latter received its name from the unequal heights of the courses. Both these methods make sound work ; first, because the stones are hard and solid, and therefore unable to absorb the moisture of the mortar, which is thus preserved to the longest period ; secondly, because the beds being smooth and level, the mortar does not escape ; and the wall, moreover, bonded throughout its whole thickness, becomes eternal. There is still another method, which is called *εμπλεκτον* (*emplectum*) (E), in use even among our country workmen. In this species the faces are wrought. The other stones are, without working, deposited in the cavity between the two faces, and bedded in mortar as the wall is carried up. But the workmen, for the sake of despatch, carry up these casing walls, and then tumble in the rubble between them, so that there are thus three distinct thicknesses, namely, the two sides or facings, and the filling in. The Greeks, however, pursue a different course, laying the stones flat, and breaking the vertical joints ; neither do they fill in the middle at random, but, by means of bond stones, make the wall solid, and of one thickness or piece. They moreover cross the wall from one face to the other, with bond stones of a single piece, which they call *διατονοι* (*diatoni*) (F), tending greatly to strengthen the work." We have preferred to give this account in the words of the author himself as the best description, because that of a practical architect, and though capable of some abbreviation, not sufficiently so to justify our own alteration.

**MASS.** (Germ. Masse.) The quantity of matter whereof any body is composed. The mass of a body is directly as the product of its volume into its density. Multiplied into the constant force of gravity, the mass constitutes the weight ; hence the mass of a body is properly estimated by its weight.

**MASTIC.** (Gr. *μαστική*, a species of gum.) A cement of recent introduction into England, employed for plastering walls. It is used with a considerable portion of linseed oil, and sets hard in a few days. From this latter circumstance, and from its being fit for the reception of paint in a very short period, it is extremely useful in works where expedition is necessary.

**MASUCCIO.** See ARCHITECTS, list of, 124.

**MATERIALS.** (Lat. Materies.) Things composed of matter, or possessing its fundamental properties. Those used in building form the subject of the second Chapter of the second Book of this work, to which the reader is referred.

**MATHEMATICS.** (Gr. *μαθημας*, learning.) The science which investigates the consequences logically deducible from any given or admitted relations between magnitude or numbers.

It has usually been divided into two parts, *pure* and *mixed*. The first is that in which geometrical magnitude or numbers are the subjects of investigation; the last, that in which the deductions so made are from relations obtained by observation and experiment from the phenomena of material nature. This is sometimes called *physics*, or physical science. On the subject of mathematics, the reader is referred, as respects what is necessary for the architect, to ARITHMETIC, and ALGEBRA, and GEOMETRY, in the body of the work, Book II. Chap. I. Sects. 1 and 2.

**MATTER.** (Lat. *Materies*.) That which constitutes substance. Of its intimate nature, the human faculty possesses no cognisance, nor either by observation or experiment can data be furnished whereon to found an investigation of it. All that we seem likely to know of it is its sensible properties, some whereof are the foundation of physical science, others of the different subordinate sciences.

**MAURITIUS.** See ARCHITECTS, list of, 86.

**MAUSOLEUM.** A term used to denote a sepulchral building, and so called from a very celebrated one erected to the memory of Mausolus, king of Caria, by his wife Artemisia, about 353 B.C. From its extraordinary magnificence, the building just mentioned was in ancient times esteemed the seventh wonder of the world. According to the account of Pliny, it was 111 feet in circumference, and 140 feet high. It is said to have been encompassed by thirty-six columns, and to have been much enriched with sculpture.

**MEAN.** In mathematics, that quantity which has an intermediate value between several others, formed according to any assigned law of succession. Thus, an *arithmetical mean* of several quantities is merely the *average*, found by dividing the sum of all the quantities by their number. A *geometrical mean* between two quantities, or a *mean proportional*, is the middle term of a duplicate ratio, or continued proportion of three terms; that is, that the first given term is to the quantity sought as that quantity is to the other given term. In arithmetic it is the square root of the product of the two given terms. The *harmonical mean* is a number such that the first and third terms being given, the first is to the third as the difference of the first and second is to the difference of the second and third.

**MEASURE.** (Lat. *Mensura*.) In geometry, strictly a magnitude or quantity taken as a unit, by which other magnitudes or quantities are measured. It is defined by Euclid as that which, by repetition, becomes equal to the quantity measured. Thus, in arithmetic, the *measure of a number* is some other number which divides it without a remainder, though, perhaps, such a definition rather intimates the notion of *aliquot parts*. But that meaning on which this article is submitted is the unit or standard by which extension is to be measured. We have measures of length, of superficies, and of volume or capacity. But the two latter are always deducible from the former; whence it is only necessary to establish one unit, namely, a standard of length. The choice of such a standard, definite and invariable, though beset with many and great difficulties, modern science has accomplished. The rude measures of our ancestors, such as the *foot*, the *cubit*, the *span*, the *fathom*, the *barleycorn*, the *hair's breadth*, are not now to be mentioned in matters of science, much more precise standards having been found, and not susceptible of casual variation. Nature affords two or three elements, which, with the aid of science, may be made subservient to the acquisition of the knowledge required. The earth being a solid of revolution, its form and magnitude may be assumed to remain the same in all ages. If this be so, the distance between the pole and the equator may be taken as an invariable quantity; and any part, say a degree, which is a ninetieth part of it, will be constant, and furnish an unalterable standard of measure. So, again, the force of gravity at the earth's surface being constant at any given place, and nearly the same at places under the same parallel of latitude, and at the same height above the level of the sea, the length of a pendulum making the same number of oscillations in a day is constant at the same place, and may be determined on any assumed scale. Thus we have two elements, the length of a degree of the meridian, and the length of a pendulum beating seconds, which nature furnishes for the basis of a system of measures. Others have been suggested, such as the height through which a heavy body falls in a second of time, determined, like the length of the pendulum, by the force of gravity, or the perpendicular height through which a barometer must be raised till the mercurial column sinks a determinate part; for instance, one-thirtieth of its own length; but these are not so capable of accurately determining the standard as the terrestrial degree, or the length of the pendulum.

By an act of Parliament passed in the year 1824, it was declared, in relation to a standard which then was in the custody of the clerk of the House of Commons, whereon were engraved the words and figures *standard yard*, 1760, but which was soon after burnt in the fire of the houses of Parliament, that it should be the unit or only standard measure of extension, and that it should be called the *imperial standard yard*. The act further declared, that if at any time thereafter the said imperial standard yard should be lost, or in any manner destroyed, defaced, or otherwise injured, it should be restored by

making, under the directions of the lords of the treasury, a new standard yard, bearing the proportion to a pendulum vibrating seconds of mean time in the latitude of London, in a vacuum, and at the level of the sea, as 36 inches to 39·1393 inches. It was afterwards found that this measure, when nicely examined, was incorrect, as respected the relation of 36 to 39·1393. It seems, too, never to have been directly compared with the pendulum; neither from the difficulty of determining the lengths of the seconds pendulum, except within limits too wide for the purpose in question, could the restoration of the standard be effected with any certainty. Perhaps the only standard that can be safely referred to at the present day is that belonging to the Royal Astronomical Society.

In the English system of linear measures, the unit, as we have above seen, is the yard, which is subdivided into 3 feet, and each of those feet into 12 inches. Of the yard, the multiples are, the pole or perch, the furlong, and the mile;  $5\frac{1}{2}$  yards being 1 pole, 40 poles being 1 furlong, and 8 furlongs 1 mile. The pole and furlong, however, are now much disused, distance being usually measured in miles and yards. The English pace is  $1\frac{1}{3}$  yards = 5 feet. Thus, the following table exhibits the relations of the different denominations mentioned:—

Inches.	Feet.	Yards.	Poles.	Furlongs.	Miles.
1	0·083	0·028	0·00505	0·00012626	0·0000157828
12	1.	0·333	0·06060	0·00151515	0·00018939
36	3.	1.	0·1818	0·004545	0·00056818
198	16·5	5·5	1.	0·025	0·003125
7920	660.	220.	40.	1.	0·125
69360	5280.	1760.	320.	8.	1.

The measures of superficies are the square yard, foot, inch, &c., as under:—

144 square inches	are equal to	-	-	-	1 square foot.
9 square feet	-	-	-	-	1 square yard.
$2\frac{1}{3}$ square yards	-	-	-	-	1 square pace.
10·89 square paces	-	-	-	-	1 square pole.
40 square poles	-	-	-	-	1 square rood.
4 square roods	-	-	-	-	1 square acre.

In which it will be seen that the multiples of the yard are the pole, rood, and acre. Very large surfaces, as of countries, are expressed in square miles. The relations of square measure are given in the following table:—

Square Feet.	Square Yards.	Square Poles.	Square Roods.	Square Acres.
1.	0·1111	0·00367309	0·000091827	0·000022957
9.	1.	0·0330579	0·000826448	0·000206612
272·25	30·25	1.	0·025	0·00625
10890.	1210.	40.	1.	0·25
43560.	4840.	160.	4.	1.

The measures of solids are cubic yards, feet, and inches, 1728 cubic inches being equal to a cubic foot, and 27 cubic feet to one cubic yard. By the act of 1824, the standard measure for all sorts of liquids, corn, and other dry goods, is declared to be the *Imperial gallon*. According to the act in question, the imperial standard gallon contains ten pounds avoirdupois of distilled water, weighed in air at the temperature of 62° Fahrenheit's thermometer, the barometer being at 30 inches. The pound avoirdupois contains 7000 troy grains, and it is declared that a cubic inch of distilled water (temperature 62°, barometer 30 inches) weighs 252·458 grains. Hence the imperial gallon contains 277·274 cubic inches. The gallon is subdivided into *quarts* and *pints*, 2 pints being one quart, and 4 quarts one gallon. Its multiples are the *peck*, which is 2 gallons, the *bushel*, which is 4 pecks, and the *quarter*, which is 8 bushels. The relations of measures of volume are given in the subjoined table:—

Pints.	Quarts.	Gallons.	Pecks.	Bushels.	Quarters.
1	0·5	0·125	0·0625	0·015625	0·001953125
2	1.	0·25	0·125	0·03125	0·00390625
8	4.	1.	0·5	0·125	0·015625
16	8.	2.	1.	0·25	0·03125
64	32.	8.	4.	1.	0·125
512	256.	64.	32.	8.	1.

The old wine gallon contained 251 cubic inches, the old corn gallon 268·8 cubic inches, and the old ale gallon 282 cubic inches. Before noticing the new French, or metre, system of measures, we subjoin a few of the principal ancient ones, English inches : —

1 toise, French	= 6 French feet	= 6·394665 English feet.
1 foot, do.	= 12 French inches	= 12·78936 English inches.
1 inch, do.	= 12 French lines	= 1·06578 English inches.
1 line, do.	= 6 French points	= 0·08815 English inches.
1 point, do.	= . . . . .	= 0·0148025 English inches.

According to General Roy, an English fathom : a French toise :: 1000 : 1065·75.

In the new French system, the *metre*, which is the unit of linear measure, is the ten-millionth part of the quadrant of the meridian = 3·2808992 English feet; and, as its multiples and subdivisions are decimally arranged and named by prefixing Greek numerals, the following table exhibits each : —

Denomination.	English Feet.
Myriametres - - - 10000 metres	= 32808·992
Kilometre - - - 1000	= 3280·8992
Hectometre - - - 100	= 328·08992
Decametre - - - 10	= 32·808992
<i>Metre</i> (the unit) - - - 1	= 3·2808992
Decimetre - - - 0·1	= 0·32808992
Centimetre - - - 0·01	= 0·032808992
Millimetre - - - 0·001	= 0·0032808992

The metre, therefore, is equal to 39·3707904 English inches.

The unit of superficial measure, in the French system, is the *are*, which is a surface of 10 metres each way, or 100 square metres. The centiare is 1 metre square.

Denomination.	English Square Yards.
Hectare - - - 10000 square metres	= 11960·33
<i>Are</i> (the unit) - - 100	= 119·6033
Centiare - - - 1	= 1·196033

The are, therefore, is equal to 1076·4297 English square feet.

The unit of measures of capacity, in the French system, is the *litre*, a vessel containing a cube of a tenth part of the metre, and equivalent to 0·22009668 British imperial gallon. Its multiples and subdivisions are as follow : —

Denomination.	Eng. Imp. Gallons.
Kilolitre - - - 1000 litres	= 220·09668
Hectolitre - - - 100	= 22·009668
Decalitre - - - 10	= 2·2009668
<i>Litre</i> (the unit) - - 1	= 0·22009668
Decilitre - - - 0·1	= 0·02209668

The unit of solid measure, or the *stere*, is equal to 35·31658 English cubic feet; therefore,

Denomination.	English Cubic Feet.
Decastere - - - 10 steres	= 353·1658
<i>Stere</i> (the unit) - - 1	= 35·31658
Decistere - - - 0·1	= 3·531658

Under the word *Foor* will be found the length of that measure in the principal places of Europe. We here think it right to add some further continuation of that article as drawn up by the late Dr. Thomas Young from Hutton, Cavallo, Howard, Vega, and others.

The uncertainty respecting the ancient Greek and Roman measures had almost induced us to refrain from setting down the usually received notions on those subjects, but as we may be accused by the omission of neglect, we subjoin some few:—

## SCRIPTURE LONG MEASURE.

	English Feet.	Inches.
1 digit	= 0	0'912
4 digits = 1 palm	= 0	3'648
3 palms = 1 span	= 0	10'944
2 spans = 1 cubit	= 1	9'888
4 cubits = 1 fathom	= 7	3'552
1½ fathoms = 1 reed (Ezekiel's)	= 10	11'328
1½ reeds = 1 pole (Arabian)	= 14	7'104
10 poles = 1 scenus, or measuring line	= 145	1'104

## GRECIAN LONG MEASURE.

		English		
		Paces of 5 ft.	Ft.	In.
1	dactylus, or digit - - - -	= 0	0	0.7554
4	dactyli = 1 doron, or dochme, or palesta -	= 0	0	3.0218
2½	palestre, &c. = 1 lichas - - - -	= 0	0	7.5546
1½	lichas = 1 orthodoron - - - -	= 0	0	8.3101
1½	orthodoron = 1 spithame - - - -	= 0	0	9.0656
1½	spithame = 1 pous, or foot - - - -	= 0	1	0.0875
1½	pous = 1 pygme, or cubit - - - -	= 0	1	1.5984
1½	pygme = 1 pygons - - - -	= 0	1	3.109
1½	pygon = 1 pecus, or larger cubit - - - -	= 0	1	6.13125
4	pecus = 1 orgye, or pace - - - -	= 0	6	0.525
100	orgya, or paces = 1 stadium, aulus, or furlong -	= 100	4	4.5
8	stadia, &c. = 1 million, or mile - - - -	= 805	5	0

## ROMAN LONG MEASURE.

		English		
		Paces.	Ft.	In.
6	scrupula = 1 sicilicum.	-	= 0	0
8	scrupula = 1 duellum.	-	= 0	0
1½	duellum = 1 semniaria.	-	= 0	0
18	scrupulas = 1 digitus transversus -	= 0	0	0.725
1½	digiti = 1 uncia, or inch - - - -	= 0	0	0.967
3	uncia = 1 palma minor - - - -	= 0	0	2.901
4	palmae = 1 pes, or foot - - - -	= 0	0	11.604
1½	pes, or foot = 1 palmipes - - - -	= 0	1	2.505
1½	palmipes = 1 cubit - - - -	= 0	1	5.406
1½	cubits = 1 gradus - - - -	= 0	2	5.01
2	gradus = 1 passus - - - -	= 0	4	10.02
2	passus = 1 decempeda - - - -	= 1	4	8.04
25	passus = 1 stadium - - - -	= 120	4	4.5
8	stadia = 1 milliare, or mile - - - -	= 967	0	0

**MECHANICS.** (Gr. Μηχανή, machine.) That science in natural philosophy treating of forces and powers, and their action on bodies, either directly or by the intervention of machinery. The theory of mechanics is founded on an axiom or principle, called the *law of inertia*, namely, that a body must remain for ever in a state of rest, or in a state of uniform or rectilinear motion, if undisturbed by the action of an external cause. Theoretical mechanics consists, therefore, of two parts: — *Statics*, which treats of the equilibrium of forces; and *dynamics*, or the science of accelerating or retarding forces, and the actions they produce. (See Book II. Chap. I. Sect. 8.) When the bodies under consideration are in a fluid state, these equilibria become respectively *hydrostatics* and *hydrodynamics*.

**MECHANICAL CARPENTRY.** That branch of carpentry which relates to the disposition of the timbers of a building in respect of their relative strength and the strains to which they are subjected. See Book II. Chap. I. Sect. 11.

**MECHANICAL POWERS.** See MACHINE.

**MEDALLION.** A square, or, more properly, a circular table, on which are embossed figures, busts, and the like.

**MEDIAEVAL ARCHITECTURE.** The architecture of England and the Continent during the middle ages, including the Norman and early Gothic styles.

**MELSONBY.** See ARCHITECTS, list of, 113.

**MEMBER.** (Lat.) Any part of an edifice or any moulding in a collection of mouldings, as of those in a cornice, capital, base, &c.

**MENAGERIE.** (Fr.) A building for the housing and preservation of rare and foreign animals. The ancient Romans of opulence usually had private menageries, a sort of small park attached to their villa, and in them various kinds of animals were placed.

**MENSURATION.** (Lat.) The science which teaches the method of estimating the magnitudes of lines, superficies, and bodies. See Book II. Chap. I. Sect. 7.; as applied to measuring and estimating buildings, see Book II. Chap. III. Sect. 14.

**MERCIER, DE.** See ARCHITECTS, list of, 262.

**MERIDIAN LINE.** A line traced on the surface of the earth coinciding with the intersection of the meridian of the place with the sensible horizon. It is therefore a line which lies due north and south. In Italy we often find these lines in large churches, as at Santa Maria del Fiore at Florence, the Duomo at Bologna, &c. They are traced on brass rods let into the pavement of the church, and marked with the signs, and otherwise graduated. A hole in the roof permits the sun's rays to fall on them at his culmination, thus marking noon as well as his height each day in the heavens.

**MERLIANO.** See **ARCHITECTS**, list of, 204.

**MEROS.** (Gr.) The plane face between the channels in the triglyphs of the Doric order.

**MESAUŁÆ.** (Gr.) Described by Vitruvius as *itineræ* or passages; they were, however, smaller courts. Apollonius Rhodius, in describing the reception of the Argonauts at the palace of Æetes, conducts them first into the vestibule, then through the folding gates into the mesaula, which had *thalami* here and there, and a portico (*αὐβωρα*) on every side.

**META.** (Lat.) A mark or goal in the Roman circus to which the chariots, &c. ran.

**METAL.** (Gr. *Μεταλλον*.) A firm, heavy, and hard substance, opaque, fusible by fire, and concreting again when cold into a solid body such as it was before; generally malleable under the hammer, and of a bright glossy and glittering substance where newly cut or broken. The metals conduct electricity and heat, and have not been resolved into other forms of matter, so that they are regarded as simple or elementary substances. Modern chemists have carried the number of metals to forty-two, only seven whereof were known to the ancients; namely, — 1. *Gold*, whose symbol is thus marked ☉; 2. *Silver*, ☿; 3. *Iron*, ♂; 4. *Copper*, ♀; 5. *Mercury*, ☿; 6. *Lead*, ♄; 7. *Tin*, ♀. The metals of most use in building are treated of in Book II. Chap. II. Sections 5, 6, and 7.

**METATOME.** (Gr. *Μετα*, and *Τεμνω*, I cut.) The space or interval between two dentels.

**METOCHE.** (Probably from *Μερεχω*, I divide.) In ancient architecture a term used by Vitruvius to denote the interval or space between the dentels of the Ionic, or triglyphs of the Doric order. Baldus observes that in an ancient MS. copy of that author, the word *metatome* is used instead of *metoche*. This made Daviler suspect that the common text of Vitruvius is corrupt, and that the word should not be *metoche* but *metatome*, as it were *section*.

**METOPA.** (Gr. *Μετα*, between, and *Ὠπή*, a hole.) The square space in the frieze between the triglyphs of the Doric order: it is left either plane or decorated, according to the taste of the architect. In the most ancient examples of this order the metopa was left quite open, whereof notice has been taken at p. 57. in the body of the work.

**METRODORUS.** See **ARCHITECTS**, list of, 52.

**MEZZANINE.** (Ital. *Mezzano*, middle.) A story of small height introduced between two higher ones.

**MEZZO RELIEVO.** See **RELIEVO**.

**MICHELOZZI.** See **ARCHITECTS**, list of, 148.

**MIDDLE POST.** In a roof, the same as **KING POST**.

**MIDDLE QUARTERS OF COLUMNS.** A name given to the four quarters of a column divided by horizontal sections, forming angles of forty-five degrees on the plan.

**MIDDLE RAIL.** The rail of a door level with the hand, on which the lock is usually fixed.

**MILE.** (Lat. *Mille passuum*, a thousand paces.) A measure of length in England equal to 1760 yards. The Roman pace was 5 feet; and a Roman foot being equal to 11·62 modern inches, it follows that the ancient Roman mile was equivalent to 1614 English yards, or very nearly eleven twelfths of an English statute mile. The measure of the English mile is incidentally defined by an act of parliament passed in the 35th of Elizabeth, restricting persons from erecting new buildings within three miles of London, in which act the mile is declared to be 8 furlongs of 40 perches each, and each perch equal to 16½ feet.

**MILK ROOM.** See **DAIRY**.

**MILLSTONE GRIT.** A coarse grained quartzose sandstone. It is extracted from the group of strata which occur between the mountain limestone and the superincumbent coal formations.

**MINARET.** (Arab. *Menarah*, a lantern.) A slender lofty turret, rising by different stages or stories, surrounded by one or more projecting balconies, common in Mohammedan countries, being used by the priests for summoning (from the balconies) the people to prayers at stated periods of the day.

**MINION.** An iron ore which, mixed with a proper quantity of lime, makes an excellent water cement.

**MINSTER.** A church to which an ecclesiastical fraternity has been or is attached. The name is applied occasionally to cathedrals, as in the case of York Minster.

**MINUTE.** (Lat.) A term given to the sixtieth part of the lower diameter of a column, being a subdivision used for measuring the minuter parts of an order.

**MISCHIA.** See **SCAGLIOLA**.

**MITCHEL.** A name given by workmen to Purbeck stones of twenty-four by fifteen inches when squared for building.

**MITER OF MITRE.** See **BEVEL**.

**MITER BOX.** See **BOX FOR MITER**.

**MIXED ANGLE.** An angle of which one side is a curve and the other a straight line.

**MIXED FIGURE.** One composed of straight lines and curves, being neither entirely tho

sector nor the segment of a circle, nor the sector nor segment of an ellipsis, nor a parabola, nor an hyperbola.

**MNESICLES.** See **ARCHITECTS**, list of, 14.

**MNESTHES.** See **ARCHITECTS**, list of, 20.

**MOAT.** (Lat.) An excavated reservoir of water surrounding a house, castle, or town.

**MODEL.** (Lat.) An original or pattern proposed for any one to copy or imitate. Thus St. Paul's may be, though not strictly so, said to be built after the model of St. Peter's at Rome.

The word is also used to signify an artificial pattern made of wood, stone, plaster, or other material, with all its parts and proportions, for the satisfaction of the proprietor, or for the guide of the artificers in the execution of any great work. In all great buildings, the only sure method of proceeding is to make a model in relievo, and not to trust entirely to drawings.

**MODILLION.** (Fr.) A projection under the corona of the richer orders resembling a bracket. In the Grecian Ionic there are no modillions, and they are seldom found in the Roman Ionic. Those in the frontispiece of Nero at Rome consist of two plain faces separated by a small cyma reversa, and crowned with an ovolo and bead. In the frieze of the fourth order of the Coliseum, the modillions are cut in the form of a cyma reversa. For further information on the subject the reader may refer to p. 797. in the body of the work.

**MODULAR PROPORTION.** That which is regulated by a module. See **MODULE**.

**MODULATION.** (Lat.) The proportion of the different parts of an order.

**MODULE.** (Lat.) A measure which may be taken at pleasure to regulate the proportions of an order, or the disposition of the whole building. The diameter or semi-diameter of the column at the bottom of the shaft has usually been selected by architects as their module; and this they subdivide into parts or minutes. Vignola has divided his module, which is a semi-diameter, into 12 parts for the Tuscan and Doric, and into 18 for the other orders. The module of Palladio, Cambray, Desgodetz, Le Clerc, and others, is divided into 30 parts or minutes in all the orders. Some have divided the whole height of the column into 20 parts for the Doric, 22½ for the Ionic, 25 for the Corinthian, &c., one whereof is taken for the module by which the other parts are to be regulated.

There are two ways by which the measures or proportions of buildings may be determined. First, by a constant standard measure, which is commonly the diameter of the lower part of the column, termed a module, and subdivided into sixty parts called minutes. In the second there are no minutes, nor any certain or stated divisions of the module, but it is divided into as many parts as may be deemed requisite. Thus the height of the Attic base, which is half the module, is divided into three to obtain the height of the plinth, or into four for that of the greater torus, or into six for that of the lesser torus. Both these species of measurement have been used by ancient as well as modern architects, but the latter was that chiefly used by the ancients, and was preferred by Perrault.

Vitruvius having lessened his module in the Doric order, which in the other orders is the diameter of the lower part of the column, and having reduced the great module to a mean one, which is a semi-diameter, Perrault reduces the module to a third part for a similar reason, namely, that of determining the different measurements without a fraction. Thus, in the Doric order, besides that the height of the base, as in the other orders, is determined by one of these mean modules, that same module furnishes the height of the capital, architrave, triglyphs, and metopæ. But the smaller module obtained from a third of the diameter of the lower part of the column has uses considerably more extensive, inasmuch as by it the heights of pedestals, of columns, and entablatures in all the orders may be obtained without a fraction.

**MODULUS OF ELASTICITY.** A term in relation to elastic bodies, which expresses the weight of themselves continued, which would draw them to a certain length without destroying their elastic power.

**MOLE.** (Sax.) A pier of stone for the shelter of ships from the action of the waves.

Amongst the Romans the term was applied, as in the case of the mole of Adrian (castle of St. Angelo at Rome), to a kind of circular mausoleum.

**MOMENTUM.** (Lat.) The impetus, force, or quantity of motion in a moving body. The word is sometimes used simply for the motion itself.

**MONASTERY.** A house for the reception of religious devotees, but more properly applied to one for the habitation of monks.

**MONKEY.** See **FISTUCA**.

**MONOLITHAL.** (Gr. *Monos*, one, *Lithos*, a stone.) A work consisting of a single stone; such works are found in many parts of the world.

**MONOPTERAL.** (Gr.) A species of temple of a round form, which had neither walls nor cella, but only a cupola sustained by columns. See **TEMPLE**.

**MONOTRIGLYPH.** (Gr.) A term applied to an intercolumniation in which only one triglyph and two metopæ are introduced.

**MONTEREAU, DE.** See ARCHITECTS, list of, 116.

**MONUMENT.** (Lat. *Monoeo*.) A structure raised to perpetuate the memory of some eminent person, or to serve as a durable token of some extraordinary event. Monuments at first consisted of stones built over the graves of the dead, on which were engraved the name and frequently a description of the actions of the persons whose memory they are to record. Monuments were differently formed. Thus some are pyramids, others obelisks; in some cases a square stone, in others a circular column serves the purpose.

**MOORSTONE.** A species of granite found in Cornwall and some other parts of England, and very serviceable in the coarser parts of a building. Its colours are chiefly black and white, and it is very coarse. In some parts of Ireland immense beds of it are found.

**MORESQUE ARCHITECTURE.** The style of building peculiar to the Moors and Arabs. See ARABIAN ARCHITECTURE, Book I. Chap. II. Sect. 10.

The word Moresque is also applied to a kind of painting in that style used by the Moors. It consists in many grotesque pieces and compartments, promiscuously, to appearance, put together, but without any perfect figure of man or animal. The style is sometimes called *Arabesque*.

**MORTAR.** (Dutch, *Morter*.) The calcareous cement used in building, compounded of burnt limestone and sand. See Book II. Chap. II. Sect. 10.

**MORTICE** or **MORTISE.** (Fr. *Mortoise*, probably from the Latin *Mordeo*, to bite.) In carpentry and joinery, a recessed cutting within the surface of a piece of timber, to receive a projecting piece called a *tenon*, left on the end of another piece of timber, in order to fix the two together at a given angle. The sides of the mortice are generally four planes at right angles to each other and to the surface, whence the excavation is made.

**MOSAIC.** (It. *Mosaico*.) A mode of representing objects by the inlaying of small cubes of glass, stone, marble, shells, wood, &c. It was a species of work much in repute among the ancients, as may be gathered from the numerous remains of it. It is supposed to have originated in the east, and to have been brought from Phœnicia to Greece, and thence carried to Rome. The term Mosaic work is distinguished from *marquetry* by being only applied properly to works of stone, metal, or glass. The art continues to be practised in Italy at the present day with great success.

**MOSQUE.** (Turk. *Moschet*.) A Mohammedan temple or place of worship. The earliest Arabian mosques were decorated with ranges of a vast number of columns, often belonging originally to other buildings. Those of the Turks, on the other hand, are more distinguished for the size and elevation of their principal cupolas. Each mosque is provided with a minaret, and commonly with a fountain of water, with numerous basins for ablutions.

**MOSTON.** See ARCHITECTS, list of, 170.

**MOULD.** A term used to signify a pattern or contour by which any work is to be wrought.

The *glazier's moulds* are of two sorts, one whereof is used for casting the lead into long rods or *comes*, fit for drawing through the vice in which the grooves are formed. This they sometimes call the *ingot mould*. The other is for moulding the small pieces of lead, a line thick and two lines broad, which are fastened to the iron bars of casements.

The *mason's mould*, also called *caliber*, is a piece of hard wood or iron, hollowed on the edge, answering to the contours of the mouldings or cornices to be formed. The ends or heading joints being formed as in a cornice by means of the mould, the intermediate parts are wrought down by straight-edges, or circular templets, as the work is straight or circular on the plan. When the intended surface is required to be very exact, a reverse mould is used, in order to prove the work, by applying the mould in a transverse direction of the arrises.

**MOULDS**, among plumbers, are the tables on which they cast their sheets of lead, and are simply called *tables*. They have others for casting pipes without soldering.

The moulds for foundry are described Book II. Chap. III. Sect. 11.

**MOULDINGS.** The ornamental contours or forms applied to the edges of the projecting or receding members of an order. The regular mouldings are the *fillet*, *listel*, or *annulet*; the *astragal*, or *bead*; the *torus*, the *scotia*, or *trochilus*; the *echinus*, *ovolo*, or *quarter-round*; the *cyma reversa*, *inverted cyma*, or *ogee*; the *cyma recta*, the *cavetto*, or *hollow*. See p. 684.

Mouldings are divided into two classes — Grecian and Roman. The first are formed by some conic section, as a portion of an ellipse or hyperbola, and sometimes even of a straight line in the form of a *chamfer*. The Roman mouldings are formed by arcs of circles, the same moulding having the same curvature throughout.

For Norman mouldings, see p. 174.

**MOUTH, BIRD'S.** See BIRD'S MOUTH.

**MUEL, LE.** See ARCHITECTS, list of, 254.

**MULLION** or **MUNNION.** In pointed architecture, the vertical post or bar which divides a window into several lights.

- MUNIMENT HOUSE.** A strong, properly fire-proof, apartment in public or private buildings, for the keeping and preservation of evidences, charters, seals, &c., called muniments.
- MURAL.** (Lat.) Belonging to a wall. Thus a monumental tablet affixed to a wall is called a *mural monument*; an arch inserted into or attached to a wall is called a *mural arch*; and columns placed within or against a wall are called *mural columns*.
- MUSEUM.** (Gr. *Μουσείον*.) A repository of natural, scientific, and literary curiosities, or of works of art. See Book III. Chap. III. Sect. 10.
- MUSTIUS.** See ARCHITECTS, list of, 45.
- MUTILATED CORNICE.** One that is broken or discontinued.
- MUTILATION.** (Lat.) The defacing or cutting away of any regular body. The word is applied to statues and buildings where any part is wanting.
- MUTIUS, C.** See ARCHITECTS, list of, 31.
- MUTULE.** (Lat.) A projecting ornament of the Doric cornice, which occupies the place of the modillion in the other order, and supposed to represent the ends of rafters. The mutule has always been assumed as an imitation of the end of a wooden rafter; hence, say the advocates for a timber type, they are properly represented with a declination towards the front of the coronas.
- MYLNE.** See ARCHITECTS, list of, 311.

## N.

- NAIL.** (Sax. *Nægel*.) A small metal spike for fastening one piece of timber to another. The sorts of nails are very numerous. The principal are here enumerated. *Back nails*, whose shanks are flat so as to hold fast but not open the wood. *Clump nails*, are for fastening clamps. *Clasp nails*, or *brads*, are those with flattened heads, so that they may clasp the wood. They also render the wood smooth, so as to admit of a plane going over it. The sorts of most common use in building are known by the names of *ten-penny*, *twenty-penny* and *two-shilling nails*. *Clench nails* are such as are used by boat and barge builders, sometimes with boves or nuts, but often without. They are made with clasp heads for fine work, or with the head beat flat on two sides. *Clout nails*, used for nailing clouts-on axle-trees, are flat headed, and iron work is usually nailed on with them. *Deck nails*, for fastening decks in ships and floors nailed with planks. *Dog* or *jobent nails*, for fastening the hinges of doors, &c. *Flat points* are of two sorts, *long* and *short*; the former much used in shipping, and useful where it is necessary to hold fast and draw without requiring to be clenched; the latter are furnished with points to drive into hard wood. *Lead nails*, used for nailing lead, leather, and canvas to hard wood, are the same as clout nails dipped in lead or solder. *Port nails*, for nailing hinges to the ports of ships. *Ribbing nails*, used for fastening the ribbing to keep the ribs of ships in their place while the ship is building. *Rose nails* are drawn square in the shank. *Rother nails*, chiefly used for fastening rother irons to ships. *Scupper nails*, much in use for fastening leather and canvas to wood. *Sharp nails*, much used in the West Indies, and made with sharp points and flat shanks. *Sheathing nails*, for fastening sheathing boards to ships; their length is usually three times the thickness of the board. *Square nails* are of the same shape as sharp nails, chiefly used for hard wood. *Brads* are long and slender nails without heads, used for thin deal work to avoid splitting. To these may be added *tacks*, the smallest sort whereof serve to fasten paper to wood; the *middling* for medium work; and the *larger size*, which are much used by upholsterers. These are known by the name of *white tacks*, *two-penny*, *three-penny*, and *four-penny tacks*. See ADHESION.
- NAIL-HEADED MOULDING.** One common in Norman buildings, and so called from being formed by a series of projections resembling the heads of nails or square knobs. See p. 174.
- NAKED.** A term applied either to a column or wall to denote the face or plain surface from which the projections rise.
- NAKED FLOORING.** See p. 540.
- NAKED OF A WALL.** The remote face whence the projections take their rise. It is generally a plain surface, and when the plan is circular the naked is the surface of a cylinder with its axis perpendicular to the horizon.
- NAOS OF NAVE.** (Gr. *Naos*.) See CELL.
- NATURAL BED OF A STONE.** The surface from which the laminæ were separated. In all masonry it is important to its duration that the laminæ should be placed perpendicular to the face of the work, and parallel to the horizon, inasmuch as the connecting substance of these laminæ is more friable than the laminæ themselves, and therefore apt to scale off in large flakes, and thus induce a rapid decay of the work.
- NAUMACHIA.** (Gr. from *Naos*, a ship, and *Μαχη*, a battle.) In ancient architecture, a place for the show of mock sea engagements, little different from the circus and amphitheatre, since this species of exhibition was often displayed in those buildings.

- NAVE.** (*Gr. Naos.*) The body of a church or place where the people are seated, reaching from the rail or partition of the choir to the principal entrance. See **CELL**.
- NEBULY MOULDING.** (*Lat. Nebula.*) An ornament in Norman architecture, whose edge forms an undulating or wavy line, and introduced in corbel tables and archivolts. See p. 174.
- NECK OF A CAPITAL.** The space, in the Doric order, between the astragal on the shaft and the annulet of the capital. Some of the Grecian Ionic capitals are with necks below them, as in the examples of Minerva Polias and Erechtheus, at Athens. But the Ionic order has rarely a neck to the capital.
- NEEDLE.** An horizontal piece of timber serving as a temporary support to some superincumbent weight, as a pier of brickwork, and resting upon posts or *shores*, while the lower part of a wall, pier, or building is being underpinned or repaired.
- NERVURES.** A name given by French architects to the ribs bounding the sides of a groined compartment of a vaulted roof, as distinguished from the ribs which diagonally cross the compartment.
- NET MEASURE.** That in which no allowance is made for finishing, and in the work of artificers, when no allowance is made for the waste of materials.
- NEWEL.** The upright cylinder or pillar, round which, in a winding staircase, the steps turn, and are supported from the bottom to the top. In stairs, geometrical for instance, where the steps are *pinned* into the wall, and there is no central pillar, the staircase is said to have an open *newel*.
- NICHE.** (*Fr. probably from Neostia, a nest.*) A cavity or hollow place in the thickness of a wall for the reception of a statue, vase, &c. See Book III. Chap. I. Sect. 21.
- NICOLA DA PISA.** See **ARCHITECTS**, list of, 121.
- NICON.** See **ARCHITECTS**, list of, 51.
- NIDGED ASHLAR.** A species of ashlar used in Aberdeen. It is brought to the square by means of a caviol or hammer with a sharp point, which reduces the roughness of the stone to a degree of smoothness according to the time employed. When stone is so hard as to resist the chisel and mallet, the method described is the only way in which it can be dressed.
- NOGS.** The same as **WOOD BRICKS**, which see. The term is chiefly used in the north of England.
- NOGGING.** A species of brickwork carried up in panels between quarters.
- NOGGING-PIECES.** Horizontal boards laid in brick-nogging, and nailed to the quarters for strengthening the brickwork. They are disposed at equal altitudes in the brickwork.
- NONAGON.** (*Gr.*) A geometrical figure having nine sides and nine angles.
- NORMAL LINE.** In geometry, one which stands at right angles to another line.
- NORMAN ARCHITECTURE.** See Book I. Chap. III. Sect. 2.
- NORMAND.** See **ARCHITECTS**, list of, 172.
- NOSING OF A STEP.** The projecting part of the tread-board or cover which stands before the riser. The nosing is generally rounded, so as to have a semicircular section; and in the better sort of staircases a fillet and hollow is placed under the nosing.
- NOTCH-BOARD.** A board which is grooved or notched for the reception and support of the ends of steps in a staircase.
- NOTCHING.** A hollow cut from one of the faces of a piece of timber, generally made rectangular in section.
- NUCLEUS.** (*Lat.*) In ancient architecture, the internal part of a floor, which consisted of a strong cement, over which the pavement was laid with mortar.
- NYMPHÆUM.** (*Gr.*) A name used by the ancients to denote a picturesque grotto in a rocky or woody place, supposed to be dedicated to, and frequented by, the nymphs. The Romans often made artificial nymphæa in their gardens. In Attica, the remains of a nymphæum are still to be seen decorated with inscriptions and bassi relievi, from the rude workmanship of which it may be presumed that the grotto is of very ancient date.

## O.

- OAK.** (*Sax. Ac, Æc.*) A forest tree, whose timber is, from its strength, hardness, and durability, the most useful of all in building. See Book II. Chap. II. Sect. 4.
- OBELISK.** (Probably from *Oëelos*, a spit, brooch, or spindle, or a long javelin.) A lofty pillar of a rectangular form, diminishing towards the top, and generally ornamented with inscriptions and hieroglyphics. The upper part finishes generally with a low pyramid, called a *pyramidion*. The proportion of the thickness to the height is nearly the same in all obelisks; that is, between one ninth and one tenth, and their thickness at top is never less than half, nor greater than three fourths, of that at bottom. Egypt abounded with obelisks, which were always in a single block of stone; and many have been removed thence to Rome and other places. The following table exhibits a list of the principal

obelisks whereof there is any record, or which are at present known, being thirty-three in number.

Situation.	Height.	Thickness.	
		At top.	Below.
Two large obelisks, mentioned by Diodorus Siculus -	Eng. Feet. 158·2	Eng. Feet. 7·9	Eng. Feet. 11·8
Two obelisks of Nuncoreus, son of Sesostris, according to Herodotus, Diodorus Siculus, and Pliny -	121·8	6·6	10·5
Obelisk of Rhameses, removed to Rome by Constantius	118·4	6·2	10·2
Two obelisks, attributed by Pliny to Smerres and Erapihus -	106·0	5·9	9·8
Obelisks of Nectanabis, erected near the tomb of Arsinoë by Ptolemy Philadelphus -	105·5	5·3	9·2
Obelisk of Constantius, restored and erected in front of S. Giovanni Laterano at Rome -	105·5	6·2	9·6
Part of one of the obelisks of the son of Sesostris, in the centre of the piazza in front of St. Peter's -	82·4	5·8	9·4
Two at Luxor -	79·1	5·3	8·0
Obelisk of Augustus from the Circus Maximus, now in the piazza del Popolo at Rome -	78·2	4·5	7·4
Two in the ruins at Thebes, still remaining -	72·8	5·0	7·5
Obelisk of Augustus, raised by Pius VI. in the Piazza di Monte Citorio -	71·9	4·9	7·9
Two obelisks, one at Alexandria, vulgarly called Cleopatra's Needle, and the other at Heliopolis -	67·1	5·1	8·1
Obelisk by Pliny, attributed to Sothis -	63·3	4·5	5·1
Two obelisks in the ruins of Thebes -	63·3	4·5	5·1
Great obelisk at Constantinople -	59·7	4·5	7·2
Obelisk in the Piazza Navona, removed from the Circus of Caracalla -	54·9	2·9	4·5
Obelisk at Arles -	50·1	4·5	7·4
Obelisk from the Mausoleum of Augustus, now in front of the church of Sta. Maria Maggiore at Rome -	48·3	2·9	4·3
Obelisk in the gardens of Sallust, according to Mercati -	48·3	2·9	4·3
Obelisk at Bijte in Egypt -	42·9	2·6	4·2
Small obelisk at Constantinople, according to Gyllius -	34·2	3·9	5·9
The Barberini Obelisk -	30·0	2·2	3·9
Obelisk of the Villa Mattei -	26·4	2·2	2·7
Obelisk in the Piazza della Rotunda -	20·1	2·1	2·4
Obelisk in the Piazza di Minerva -	17·6	2·0	2·6
Obelisk of the Villa Medici -	16·1	1·9	2·4

**OBLIQUE LINE.** One which stands, in respect to another, at a greater angle than ninety degrees.

**OBLIQUE ANGLE.** One that is greater or less than a right angle.

**OBLIQUE-ANGLED TRIANGLE.** One that has no right angle.

**OBLIQUE ARCHES.** Such as cross an opening obliquely to the front face of it.

**OBLONG.** A rectangle of unequal dimensions.

**OBSERVATORY.** (Fr.) A building for the reception of instruments and other matters for observing the heavenly bodies. See Book III. Chap. III. Sect. 11.

**OBUSE.** (Lat.) Any thing that is blunt.

**OBUSE-ANGLED TRIANGLE.** One which has an obtuse angle.

**OBUSE SECTION OF A CONE.** Among the ancient geometers a name given to the hyperbola.

**OCTAGON.** (Gr. *ὀκτώ* and *γωνία*, angle.) A figure having eight sides and eight angles.

**OCTAHEDRON.** (Gr.) One of the five regular bodies bounded by eight equal and equilateral triangles.

**OCTASTYLE.** (Gr. *ὀκτώ* and *στυλος*.) That species of temple or building having eight columns in front. See COLONNADE.

**ODEUM.** (Gr.) Among the Greeks, a species of theatre wherein the poets and musicians rehearsed their compositions previous to the public production of them.

**ODO.** See ARCHITECTS, list of, 88.

**ODCUS.** See HALL.

**OFFICES.** The apartments wherein the domestics discharge the several duties attached to the service of a house; as kitchens, pantries, brewhouses, and the like.

**OFFSETS.** The horizontal projections from the faces of the different parts of a wall where it increases or diminishes in thickness.

**OGEE.** A moulding, the same as the *CYMA REVERSA*, which see.

**OGIVE.** A term used by French architects to denote the Gothic vault, with its ribs and cross springers, &c. The word is used to denote the pointed arch.

**OLOLZAGO.** See *ARCHITECTS*, list of, 194.

**ONE PAIR OF STAIRS.** An expression signifying the first story or floor above that floor level with, or raised only by a few steps above, the ground, which latter is thence called the ground floor.

**OPÆ** (Gr. *Οπη.*) The beds of the beams of a floor or roof between which are the *Μετοπæ*, which see.

**OPENINGS.** (Sax.) Those parts of the walls of a building which are unfilled for admitting light, ingress, egress, &c. See *APERATURE*.

**OPISTHODOMUS.** (Gr.) The same as the Roman *posticum*, being the enclosed space behind a temple.

**OPPOSITE ANGLES.** Those formed by two straight lines crossing each other, but not two adjacent angles.

**OPPOSITE CONES.** Those to which a straight line can be applied on the surfaces of both cones.

**OPPOSITE SECTIONS.** The sections made by a plane cutting two opposite cones.

**OPTIC PYRAMID.** In perspective, that formed by the optic rays to every point of an object.

**OPTIC RAYS.** Those which diverge from the eye to every part of an original object.

**ORANGERY.** A gallery or building in a garden or parterre opposite to the south. See

*GREEN-HOUSE.* The most magnificent orangery in Europe is that of Versailles, which is of the Tuscan order, and with wings.

**ORATORY.** (Lat.) A small apartment in a house, furnished with a small altar, crucifix, &c., for private devotion. The ancient oratories were small chapels attached to monasteries, in which the monks offered up their prayers. Towards the sixth and seventh centuries the oratory was a small church, built frequently in a burial place, without either baptistery or attached priest, the service being performed by one occasionally sent for that purpose by the bishop.

**ORB.** (Lat. *Orbis.*) A knot of foliage or flowers placed at the intersection of the ribs of a Gothic ceiling or vault to conceal the mitres of the ribs.

**ORCHESTRA.** (Gr. *Ορχεσμαι.*) In ancient architecture, the place in the theatre where the chorus danced. In modern theatres it is the enclosed part of a theatre, or of a music-room wherein the instrumental and vocal performers are seated.

**ORCHEYARDE.** See *ARCHITECTS*, list of, 160.

**ORDER.** (Lat.) An assemblage of parts, consisting of a base, shaft, capital, architrave, frieze, and cornice, whose several services requiring some distinction in strength, have been contrived in five several species — Tuscan, Doric, Ionic, Corinthian, and Composite; each of these has its ornaments, as well as its general fabric, proportioned to its strength and use. There are five orders of architecture, the proper understanding and application whereof constitute the foundation of all excellence in the art. See *Book III. Chap. I. Sect. 2.* on the *ORDERS* generally.

**ORDER, COMPOSITE.** See *Book III. Chap. I. Sect. 7.*

**ORDER, CORINTHIAN.** See *Book III. Chap. I. Sect. 6.*

**ORDER, DORIC.** See *Book III. Chap. I. Sect. 4.*

**ORDER, IONIC.** See *Book III. Chap. I. Sect. 5.*

**ORDER, TUSCAN.** See *Book III. Chap. I. Sect. 3.*

**ORDERS ABOVE ORDERS.** See *Book III. Chap. I. Sect. 11.*

**ORDINATE.** In geometry and conics, a line drawn from any point of the circumference of an ellipsis or other conic section perpendicular to, and across the axis, to the other side.

**ORDONNANCE.** (Fr. from the Lat.) The perfect arrangement and composition of any architectural work. It applies to no particular class, but the term is general to all species in which there has existed anything like conventional law.

**ORGANICAL DESCRIPTION OF A CURVE.** The method of describing one upon a plane by continued motion.

**ORIEL or ORIEL WINDOW.** (Etym. uncertain.) A large bay or recessed window in a hall, chapel, or other apartment. It ordinarily projects from the outer face of the wall either in a semi-octagonal or diagonal plan, and is of varied kinds and sizes. In large halls its usual height is from the floor to the ceiling internally, and it rises from the ground to the parapet on the outside; sometimes it consists only of one smaller window supported by corbels, or by masonry projecting gradually from the wall to the sill of the window. Milner, the learned and good Catholic bishop, in his *History of Winchester*,

draws a difference between the bow and oriel window. The first projected circularly, and was formerly called a compass or embowed window; whilst the projection of the last was made up of angles and straight lines forming generally the half of a hexagon, octagon, or decagon, and was better known by the name of *bay window*, *shot window*, or *outcast window*, a distinction, however, not generally observed.

**ORIGIN AND PROGRESS OF ARCHITECTURE.** See Book I. Chap. I. Sect. 2.

**ORIGINAL LINE, PLANE, or POINT.** In perspective, a line, plane, or point referred to the object itself.

**ORLE.** (Ital.) A fillet under the ovolo or quarter round of a capital. When the fillet is at the top or bottom of the shaft of a column it is called a cincture. Palladio uses the word *orle* to express the plinth of the bases of the columns and pedestal.

**ORNAMENT.** The smaller and detailed part of the work, not essential to it, but serving to enrich it; it is generally founded upon some imitation of the works of nature.

**ORTHOGRAPHY.** (Gr. *ὀρθος*, right, and *Γραφω*, I describe.) The elevation of building showing all the parts in their proper proportions; it is either external or internal. The first is the representation of the external part or front of a building showing the face of the principal wall, with its apertures, roof of the building, projections, decorations, and all other matters as seen by the eye of the spectator, placed at an infinite distance from it. The second, commonly called the *section* of a building, shows it as if the external wall were removed, and separated from it.

In geometry, orthography is the art of representing the plan or side of any object, and of the elevation also of the principal parts: the art is so denominated from its etymology, because it determines things by perpendicular *right lines* falling on the geometrical plan, or because all the horizontal lines are straight and parallel, and not, as in perspective, oblique.

**OSCULATING CIRCLE.** That, the radius of whose curve at any particular point of another curve, is of the same length as that of the curve in question at that particular point. Hence it is the kissing circle, and that so closely, that there is no difference in the curvature of the two curves at that particular point.

**OVA.** (Lat.) Ornaments in the shape of an egg, into which the echinus or ovolo is often carved.

**OVAL.** A geometrical figure, whose boundary is a curve line returning into itself; it includes the ellipsis or mathematical oval, and all figures resembling it, though with different properties.

**OVULO.** (Ital.) A convex moulding whose lower extremity recedes from a perpendicular line drawn from the upper extremity. See **MOULDING**.

**OUT TO OUT.** An expression used of any dimension when measured to the utmost bounds of a body or figure.

**OUT OF WINDING.** A term used by artificers to signify that the surface of a body is that of a perfect plane; thus when two straight edges are in the same plane they are said to be out of winding.

**OUTER DOORS.** Those common to both the exterior and interior sides of a building

**OUTER PLATE.** See **INNER PLATE**.

**OUTLINE.** The line which bounds the contour of any object.

**OUTWARD ANGLE.** The external or salient angle of any figure.

**OVERHANG.** See **BATTER**.

## P.

**PADDLE.** A small sluice, similar to that whereby water is let into or out of a canal lock.

**PAGODA.** (Corrupted from *Poutgad*, Pers., a house of idols.) A name given to the temples of India. See **INDIAN ARCHITECTURE**. Book I. Chap. II. Sect. 6.

**PAINE.** See **ARCHITECTS**, list of, 303.

**PAINTER'S WORK.** See Book II. Chap. III. Sect. 12.

The work of painting with different coats of oil colour and turpentine the parts of a building usually so treated.

**PALACE.** (Lat. *Palatium*.) In this country, a name given to the dwelling of a king or queen, a prince, and a bishop. On the Continent, it is a term more extensively used, almost all large dwellings and government offices being so denominated. See Book III. Chap. III. Sect. 4.

**PALÆSTRA.** (Gr. *Παλαια*, I wrestle.) A part of the Grecian gymnasium, particularly appropriated to wrestling and other gymnastic exercises; it was sometimes used to denote the whole building. It contained baths which were open for the use of the public. According to the authority of Vitruvius, no palæstra existed in Rome.

**PALE.** A small pointed stake or piece of wood used for making landmarks and enclosures placed vertically.

**PALE FENCING OR PALE FENCE.** That constructed with pales.

**PALISADE.** A fence of pales or stakes driven into the ground, set up for an enclosure, or for the protection of property.

**PALLADIO.** See ARCHITECTS, list of, 241.

**PALM.** A measure of length. See MEASURE.

**PAMFRE.** (Fr.) An ornament composed of vine leaves and bunches of grapes, wherewith the hollow of the circumvolutions of twisted columns are sometimes decorated.

**PANCARPI.** (Gr.) Garlands and festoons of fruit, flowers, and leaves, for the ornament of altars, doors, vestibules, &c.

**PANEL.** (From the low Latin *panellum*.) A board whose edges are inserted into the groove of a thicker surrounding frame.

A panel in masonry is one of the faces of a hewn stone.

**PANNIER.** The same as CORBEL, which see.

**PANTAMETER.** A graduated bevel.

**PANTILES.** See Book II. Chap. II. Sect. 9.

**PANTOGRAFE.** An instrument for copying, diminishing, or enlarging drawings.

**PAPER.** A substance made by the maceration of linen rags in water and spreading them into thin sheets; on this the drawings of the architect are usually made; its usual sizes being as under:—

Demy	-	-	20 inches by 15 inches.	Atlas	-	-	34 inches by 26 inches.
Medium	-	-	22 — 17 —	Double Elephant	-	40 —	26 —
Royal	-	-	24 — 19 —	Antiquarian	-	52 —	31 —
Super-royal	-	-	27 — 19 —	Extra Antiquarian	-	56 —	40 —
Imperial	-	-	30 — 21 —	Emperor	-	68 —	48 —
Colombier	-	-	34 — 23 —				

**PAPERHANGER'S WORK.** See Book II. Chap. III. Sect. 12.

**PARABOLA.** (Gr. *Παρα*, through, and *Βαλλω*, I throw.) In geometry, a curve line formed by the common intersection of a conic surface, and a plane cutting it parallel to another plane touching the conic surface. See Book II. Chap. I. Sect. 5.

**PARABOLIC ASSYMPTOTE.** In geometry, a line continually approaching the curve, but which, though infinitely produced, will never meet it.

**PARABOLIC CURVE.** The curved boundary of a parabola, and terminating its area, except at the double ordinate.

**PARABOLIC SPIRAL, OR HELICOID.** A curve arising from the supposition of the axis of the common parabola bent into the periphery of a circle, the ordinates being portions of the radii next the circumference.

**PARABOLOID.** See CONOID.

**PARALLEL.** (Gr. *Παράλληλος*.) In geometry, a term applied to lines, surfaces, &c., that are in every part equidistant from each other.

**PARALLEL COPING.** See COPING.

**PARALLELOGRAM.** (Gr.) Any four-sided rectilineal figure, whose opposite sides are parallel.

**PARALLELOPIPED.** In geometry, one of the regular bodies or solids comprehended under six faces, each parallel to its opposite face, and all the faces parallelograms.

**PARAMETER.** (Gr. *Παρα*, through, and *Μετρο*, I measure.) In conic sections, a constant right line in each of the three sections, called also *latus rectum*.

**PARAPET.** (Ital. *Parapetto*, breast high.) A small wall of any material for protection on the sides of bridges, quays, or high buildings.

**PARASCENIUM.** Another name for the *postscenium* in the ancient theatre.

**PARASTATÆ.** See ANTÆ.

**PARGET.** A name given to the rough plaster used for lining chimney flues.

**PARKER'S CEMENT.** See p. 509.

**PARLOUR.** (Fr.) A room for conversation, which in the old monasteries adjoined the buttry and pantry at the lower end of the hall. At the present day it is used to denote the room in a house where common visitors are received.

**PARODOS.** (Gr.) The grand entrance of the scene of an ancient theatre that conducted on to the stage and orchestra.

**PARQUETRY.** See MARQUETRY.

**PARSONAGE HOUSE.** A building usually near the church, occupied by the incumbent of the living; in former times this sort of building was often embattled and fortified, and had various appendages, including sometimes a small chapel or oratory.

**PARTITION.** (Lat.) A wall of stone, brick, or timber, dividing one room from another. When a partition has no support from below it should not be suffered to bear on the floor with any considerable weight, and in such cases it should have a *truss* formed within, in which case it is called a *trussed partition*. See TRUSS.

**PARTY WALLS.** Such as are formed between houses to separate them from each other and

- prevent the spreading of fire. The regulations prescribed for them form a large portion of the Building Act of 14 Geo. III. See Building Act at length, p. 819, *et seq.*
- PARTY FENCE WALL.** A wall separating the vacant ground in one occupation from that in another. See Building Act, p. 819, *et seq.*
- PARVIS.** (Etym. uncertain.) A porch portico or large entrance to a church. It seems also to have signified a room over the church porch, where schools used to be held.
- PASSAGES.** The avenues leading to the various divisions and apartments of a building. When there is only one series of rooms in breadth, the passage must run along one side of the building, and may be lighted by apertures through the exterior walls. If there be more than one room in breadth, it must run in the middle, and be lighted from above or at one or both ends.
- PATERA.** (Lat.) A vessel used in the Roman sacrifices, wherein the blood of the victims was received. It was generally shallow, flat, and circular. Its representation has been introduced as an ornament in friezes and fasciæ, accompanied with festoons of flowers or husks, and other accessories.
- PATERNOSTERS.** A species of ornament in the shape of beads, either round or oval, used in baguettes, astragals, &c.
- PAUTRE, LE.** See ARCHITECTS, list of, 261.
- PAVEMENT.** (Lat. Pavimentum.) A path or road laid or beaten in with stones or other materials. According to the information of Isidorus, the first people who paved their streets with stone were the Carthaginians. Appius Claudius, the founder of the Appian Way, appears to have introduced the practice into Rome, after which the Roman roads were universally paved, remains of them having been found in every part of the empire.
- In the interior of the Roman houses, the pavement was often laid upon timber framing; and the assemblages so constructed were called *contignata pavimenta*. The pavement called *coassatio* was made of oaken planks of the *quercus esculus*, which was least liable to warp. The Roman pavements were also frequently of mosaic work, that is, of square pieces of stone, called tesserae, in various patterns and figures, many of which remain in Britain to the present day.
- The various sorts of paving are as follows:—1. *Pebble paving*, of stones collected from the sea beach, mostly obtained from Guernsey or Jersey. This is very durable if well laid. The stones vary in size, but those from six to nine inches deep are the best. Those of three inches in depth are called *bolders* or *boulters*, and are used for paving court-yards and those places where over-heavy weights do not pass. 2. *Rag paving*: inferior to the last, and usually from the vicinity of Maidstone, in Kent, whence it bears the name of Kentish rag stone. It is sometimes squared, and then used for paving coach-tracks and footways. 3. *Purbeck pitchers*, which are square stones, used in footways, brought from the island of Purbeck. They are useful in court-yards: the pieces running about five inches thick, and from six to ten inches square. 4. *Squared paving*, by some called *Scotch paving*, of a clear close stone, called *blue wynn*. This is now, however, quite out of use. 5. *Granite*, of the material which its name imports. 6. *Guernsey paving*, which, for street work, is the best in use. It is broken with iron hammers, and squared to any required dimensions, of a prismatic figure, with a smaller base downwards. It is commonly bedded in small gravel. 7. *Purbeck paving*, used for footways, of which the blue sort is the best, is obtained in pretty large surfaces, of about two inches and a half thick. 8. *Yorkshire paving*: a very good material, and procurable of very large dimensions. 9. *Ryegate* or *fire-stone paving*, used for hearths, stoves, ovens, and other places subject to great heat, by which this stone, if kept dry, is not affected. 10. *Newcastle flags*, useful for the paving of offices. They run about one and a half to two inches thick, and about two feet square, and bear considerable resemblance to the Yorkshire. 11. *Portland paving* may be had from the island of Portland of almost any required dimensions. The squares are sometimes ornamented by cutting away their angles, and inserting small black marble squares, set diagonally. 12. *Sweedland paving*: a black slate dug in Leicestershire, useful for paving halls or for party-coloured paving. 13. *Marble paving*, of as many sorts almost as there are species of marble. It is sometimes inlaid after the manner of Mosaic work. 14. *Flat brick paving*, executed with bricks laid flat in sand, mortar, or grout, when liquid lime is poured into the joints. 15. *Brick or edge paving*, executed in the manner of the last, except that the bricks are laid on edge. 16. *Herring-bone paving*: bricks laid diagonally to each other. See **HERRING-BONE WORK**. 17. *Bricks laid endwise* in sand, mortar, or grout. 18. *Paving bricks*, are made especially for the purpose, and are better than stocks. 19. *Ten-inch tile paving*. 20. *Foot tile paving*. 21. *Clinker paving*.

The pavements of churches are often in patterns of several colours, of which, to shew the great variety that may be obtained from a few colours, M. Truchet (*Mém. Acad. Fran.*) has proved that two square stones, divided diagonally into two colours, may be joined together chequerwise in sixty-four different ways.

**PAVEMENT (DIAMOND.)** That in which the stones, flags, or bricks are laid with their diagonals perpendicular to the sides of the apartment.

**PAVILION.** (Ital. Padiglione.) A turret or small building, generally insulated and comprised under a single roof. The term is also applied to the projecting parts in the front of a building. They are usually higher than the rest of the building.

**PEDESTAL.** (Compound, apparently, of *Pes*, a foot, and *Στυλος*, a column.) The lowest division in an order of columns, called also *stylobates* and *stereobates*. It consists of three principal parts: the die, the cornice, and the base. See Book III. Chap. I. Sect. 8.

**PEDIMENT.** The triangular crowning part of a portico or aperture, which terminates vertically the sloping parts of the roof. In Gothic architecture, this triangular piece is much higher in proportion to its width, and is denominated a gable. The subject of pediments is fully treated of in Book III. Chap. I. Sect. 17.

**PELAGIC ARCHITECTURE.** See Book I. Chap. II. Sect. 2.

**PENDENT.** (Lat.) An ornament suspended from the summit of Gothic vaulting, very often elaborately decorated. The mode in which stone pendants are constructed, will be immediately understood by a consideration of the annexed figure. The pendent was also used very frequently to timber-framed roofs, as in that of Crosby Hall, which has a series of pendants along the centre of it. Pendants are also attached to the ends of the hammer beams in Gothic timber roofs.

**PENDENTIVE.** The entire body of a vault suspended out of the perpendicular of the walls, and bearing against the arch boutants, or supporters. It is defined by Daviler to be the portion of a vault between the arches of a dome, commonly enriched with sculpture. Felibien defines it as the plane of the vault contained between the double arches, the forming arches, and the ogives. See p. 560.

**PENDENTIVE BRACKETING or CAVE BRACKETING.** That springing from the rectangular walls of an apartment upwards to the ceiling, and forming the horizontal part of the ceiling into a circle or ellipsis.

**PENDENTIVE CRADLING.** The timber work for sustaining the lath and plaster in vaulted ceilings.

**PENETRALE.** (Lat.) The most sacred part of the temple, which generally contained an altar to Jupiter Hercæus, which appellation, according to Festus, was derived from *ἔκρος*, an enclosure, and supposed him the protector of its sanctity.

**PENETRALIA.** (Lat.) Small chapels dedicated to the Penates, in the innermost part of the Roman houses. In these it was the custom to deposit what the family considered most valuable.

**PENITENTIARY.** In monastic establishments was a small square building, in which a penitent confined himself. The term was also applied to that part of a church to which penitents were admitted during divine service. The word, as used in the present time, implies a place for the reception of criminals whose crimes are not so heinous as to deserve punishment beyond that of solitary confinement and hard labour, and where means are used to reclaim as much as possible those who have become subject to the laws by transgressing them. See PRISON, Book III. Chap. III. Sect. 18.

**PENSTOCK.** A small paddle, working up and down vertically in a grooved frame, for penning back water.

**PENTADORON.** (Gr.) A species of brick used in ancient architecture, which was five palms long.

**PENTAGON.** (Gr. Πεντε, five, and γωνία, an angle.) In geometry, a figure of five sides and five angles. When the five sides are equal, the angles are so too, and the figure is called a regular pentagon.

**PENTAGRAPH.** See PANTOGRAPH.

**PERIACTL.** (Gr. Περίακτω, to revolve.) The revolving scenes in an ancient theatre, called by the Romans *scenæ frons*.

**PERIBOLUS.** (Gr.) A court or enclosure within a wall, sometimes surrounding a temple. It was frequently ornamented with statues, altars, and monuments, and sometimes contained other smaller temples or a sacred grove. The peribolus of the temple of Jupiter Olympius, at Athens, was four stadia in circumference.

**PERICL.** See ARCHITECTS, list of, 317.

**PERCY.** See ARCHITECTS, list of, 184.

**PEREZ.** See ARCHITECTS, list of, 126.

**PERIDROME.** (Gr. Περί, about, Δρομος, a course.) The space, in ancient architecture, between the columns of a temple and the walls enclosing the cell.

**PERIMETER.** (Gr.) The boundary of a figure.

**PERIPHERY.** (Gr. Περιφέρεια, I surround.) The circumference of a circle, ellipsis, parabola, or other regular curvilinear figure.

**PERITYTERY.** (Gr.) The range of insulated columns round the cell of a temple.

- PERIPTERAL.** (Gr.) A temple surrounded by a periptery, that is, encompassed by columns. See **TEMPLE**.
- PERISTYLIUM.** (Gr.) In Greek and Roman buildings, a court, square or cloister, which sometimes had a colonnade on three sides only, and therefore in that case improperly so called. Some peristylia had a colonnade on each of the four sides; that on the south being sometimes higher than the rest, in which case it was called a *Rhodian peristylum*. The range of columns itself was called the *peristyle*. See **COLONNADE**.
- PERITHYRIDES.** The same as **ANCONES**, which see.
- PERITROCHIUM.** (Gr.) A term in mechanics applied to a wheel or circle concentric with the base of a cylinder, and together with it moveable about an axis.
- PERPENDICULAR.** In geometry, a term applied to a right line falling directly on another line, so as to make equal angles on each side, called also a *normal line*. The same definition will hold of planes standing the one on the other. A perpendicular to a curve is a right line cutting the curve in a point where another right line to which it is perpendicular makes a tangent with the curve.
- PERPEND STONE OR PERPENDER.** A long stone reaching through the thickness of the wall, so as to be visible on both sides, and therefore wrought and smoothed at the ends.
- PERRAULT.** See **ARCHITECTS**, list of, 259.
- PERRON.** A French term, denoting a staircase, lying open or without side the building; or more properly the steps in the front of a building which lead into the first story, where it is raised a little above the level of the ground.
- PERRONET.** See **ARCHITECTS**, list of, 298.
- PERSIAN OR PERSEPOLITAN ARCHITECTURE.** See **Book I. Chap. II. Sect. 4.**
- PERSIANS.** See **CARYATIDES**.
- PERSPECTIVE.** (Lat. *Perspicio*.) The science which teaches the art of representing objects on a definite surface, so as from a certain position to affect the eye in the same manner as the objects themselves would. This art forms the subject of **Book II. Chap. IV. Sect. 2.**
- PERUZZI.** See **ARCHITECTS**, list of, 200.
- PEST HOUSE.** A lazaretto or infirmary where persons, goods, &c., infected with the plague or other contagious disease, or suspected so to be, are lodged to prevent communication with others, and the consequent spread of the contagion.
- PETER OF COLECHUCH.** See **ARCHITECTS**, list of, 106.
- PHÆAX.** See **ARCHITECTS**, list of, 28.
- PHALANGÆ.** (Gr.) A name applied by Vitruvius to a species of wooden rollers, used to transport heavy masses from one spot to another.
- PHAROS.** (Gr. from *Φῶς*, a light, and *Ὀρῶω*, I see.) The name applied to an ancient light-house. See **Book III. Chap. III. Sect. 12.**
- PHEASANTRY.** A building or place for the purpose of breeding, rearing, and keeping pheasants.
- PHILO.** See **ARCHITECTS**, list of, 26.
- PHONICS.** The doctrine of sounds, which has not yet been so reduced in its application to architecture as to have justified in this work more than its definition in this place. See the **Sect. 16. Chap. III. Book III. on THEATRES.**
- PHOTOMETER.** (Gr.) An instrument for measuring the different intensities of light.
- PIAZZA.** (Ital.) A square open space surrounded by buildings. The term is very frequently and very ignorantly used to denote a walk under an arcade.
- PIEDROIT.** (Fr.) A French term, signifying a pier or square pillar, partly hid within a wall. It differs from a pilaster in having neither base nor capital.
- PIER.** (Fr.) A solid between the doors or windows of a building. The square or other formed mass or post to which a gate is hung. Also the solid support from which an arch springs. In a bridge, the pier next the shore is usually called an *abutment pier*.
- PIETRO DI GAMIEL.** See **ARCHITECTS**, list of, 195.
- PIETRO SAN.** See **ARCHITECTS**, list of, 119.
- PILASTER.** (Fr.) A sort of square column, sometimes insulated, but more commonly engaged in a wall, and projecting only a fourth or fifth of its thickness. See **Book III. Chap. I. Sect. 14.**
- PILES.** (Lat.) Large timbers driven into the earth, upon whose heads is laid the foundation of a building in marshy and loose soils. Amsterdam and some other cities are built wholly upon piles. The stoppage of Dagenham Breach was effected by piles mortised into one another by dovetail joints. They are best and most firmly driven by repeated strokes; but for the saving of time, a pile engine is generally used, in appearance and effect very much like a guillotine, which, having raised the *monkey* or hammer to a certain height, lets it, by pressing the clasps which carry it up, suddenly drop down on the pile to be driven.
- PILLAR.** (Fr. *Pilier*.) A column of irregular form, always disengaged, and always de-

- viating from the proportions of the orders, whence the distinction between a column and a pillar. In any other sense it is improperly used.
- PIN.** In carpentry, a cylindrical piece of wood driven to connect pieces of framing together.
- PINNACLE.** (Low Lat. *Pinnaculum*.) A summit or apex. The term is usually applied to the ornament in Gothic architecture placed on the top of a buttress, or as the termination to the angle of the gable of a building. It is also placed on different parts of a parapet, at the sides of niches, and in other situations. Its form is usually slender, and tapers to a point.
- PINNING UP.** In underpinning the driving the wedges under the upper work so as to bring it fully to bear upon the work below.
- The term pinning is also used to denote the fastening of tiles together with pins or pieces of heart of oak in the covering of buildings.
- PINO, DL.** See ARCHITECTS, list of, 201.
- PINTELL.** See ARCHITECTS, list of, 155.
- PIPE.** A conveyance for water or soil from any part of a building, usually of lead or iron. When for the supply of water to a building it is called a *service pipe*; when for carrying off water, a *waste pipe*; and when for carrying off soil, a *soil pipe*; and those which carry away the rain from a building are called *rain-water pipes*. When a cistern or reservoir is supplied in such a way that those who labour to fill it should be made aware that it is full, the pipe which discharges the overflow is called a *warning pipe*.
- PIPP.** See ARCHITECTS, list of, 218.
- PISCINA.** (Lat.) Among the Romans this term was applied to a fish-pond, to a shallow reservoir for practising swimming, and to a place for watering horses and washing clothes. The piscina in ecclesiastical architecture was a bowl for water, generally in a niche in the wall of the church wherein the priest laved his hands. There was usually one attached to every altar for the priest to wash his hands on the performance of the sacred rites. The variety of their form is great; some were extremely simple, others very richly decorated.
- PISÉ.** A species of walling, of latter years used in France, made of stiff earth or clay rammed in between moulds as it is carried up. This method of walling was however in very early use. (*Plin. lib. xxxiv. chap. 14.*)
- PIT OF A THEATRE.** The part on the ground-floor between the lower range of boxes and the stage.
- PITCH.** A term generally applied to the vertical angles formed by the inclined sides of a roof.
- PITCHING PIECE.** In staircasing, an horizontal piece of timber, having one of its ends wedged into the wall at the upper part of a flight of steps, to support the upper ends of the *rough strings*. See APRON PIECE.
- PIVOT.** (Fr.) The sharpened point upon which a perpendicular wheel performs its revolutions.
- PLACE BRICKS.** See p. 504.
- PLAFOND or PLATFOND.** (Fr.) The ceiling of a room, whether flat or arched; also the under-side of the projection of the larmier of the cornice; generally any sofit.
- PLAIN or PLANE ANGLE.** One contained under two lines and surfaces, so called to distinguish it from a solid angle.
- PLAIN TILES, properly PLANE TILES.** Those whose surfaces are planes. See Book II. Chap. II. Sect. 9.
- PLAN.** (Fr.) The representation of the horizontal section of a building, showing its distribution, the form and extent of its various parts. In the plans made by the architect, it is customary to distinguish the massive parts, such as walls, by a dark colour, so as to separate them from the voids or open spaces. In a *geometrical plan*, which is that above mentioned, the parts are represented in their natural proportions. A *perspective plan* is drawn according to the rules of perspective. The *raised plan* of a building is the elevation of it.
- PLANCER.** The same as the sofit or under-surface of the corona; the word is however very often used generally to mean any sofit.
- PLANE.** (Lat. *Planus*.) A tool used by artificers that work in wood for the purpose of producing thereon a flat even surface. There are various sorts of planes, whose description will be found at p. 564.
- PLANE.** In geometry, a surface that coincides in every direction with a straight line.
- PLANE, GEOMETRICAL.** In perspective, a plane parallel to the horizon, whereon the object to be delineated is supposed to be placed. It is usually at right angles with the perspective plane.
- PLANE, HORIZONTAL.** In perspective, a plane passing through the spectator's eye, parallel to the horizon, and cutting the perspective plane in a straight line, called the *horizontal line*.
- PLANE, INCLINED.** One that makes an oblique angle with a horizontal plane.

- PLANE, OBJECTIVE.** Any plane, face, or side of an original object to be delineated on the perspective plane.
- PLANE, PERSPECTIVE.** That interposed between the original objects and the eye of the spectator, and whereon the objects are to be delineated.
- PLANE TRIGONOMETRY.** See Book II. Chap. I. Sect. 4.
- PLANIMETRY.** That branch of geometry which treats of lines and surfaces only, without reference to their height or depth.
- PLANK. (Fr.)** A name given generally to all timber, except fir, which is less than four inches thick and thicker than one inch and a half. See **BOARD**.
- PLASTER AND PLASTERER'S WORK.** See Book II. Chap. III. Sect. 9.
- PLASTER OF PARIS.** A preparation of gypsum, originally procured in the vicinity of Mont Martre near Paris. The plaster stone, or alabaster, is, however, found in many parts of England, as at Chelaston near Derby, and Beacon Hill near Newark. The former pits yield about 800 tons a year. It is ground and frequently used for manure, or rather as a stimulant for grass. It is calcined into the plaster used by the modeller, plasterer, &c. When diluted with water into a thin paste, plaster of Paris sets rapidly, and at the instant of setting, its bulk is increased. Mr. Boyle found by experiment that a glass vessel filled with this paste, and close stopped, bursts while the mixture sets, a quantity of water sometimes issuing through the cracks; hence this material becomes valuable for filling cavities, &c., when other earths would shrink. The gypsum is prepared either by burning or boiling, and loses from four to six cwt. in a ton. After burning, it is ground into powder in a mill.
- PLATBAND.** Any flat and square moulding whose projection is much less than its height, such are the fasciæ of an architrave, the list between flutings, &c. The platband of a door or window is the lintel, when it is made square and not much arched.
- PLATE.** A general term applied to those horizontal pieces of timber lying mostly on walls for the reception of another assemblage of timbers. Thus, a *wall plate* is laid round the walls of a building to receive the timbering of a floor and roof; a *gutter plate* under the gutter of a building, &c.
- PLATE GLASS.** See **GLASS**.
- PLATE RACK.** A fixture over the sink in a scullery for the reception of dinner plates and dishes after washing.
- PLATFORM.** An assemblage of timbers for carrying a flat covering of a house, or the flat covering itself. A terrace or open walk at the top of a building.
- PLINTH. (Gr. Πλινθος, a brick.)** The lower square member of a base of a column or pedestal. In a wall the term *plinth* is applied to two or three rows of bricks which project from the face.
- PLOTTING.** The art of laying down on paper the angles and lines of a plot of land by any instrument used in surveying.
- PLUG.** A piece of timber driven perpendicularly into a wall with the projecting part sawn away, so as to be flush with the face.
- PLUG AND FEATHER, or KEY AND FEATHER.** A name given to a method of dividing hard stones by means of a long tapering wedge, called the *key*, and wedge-shaped pieces of iron called *feathers*, which are driven into holes previously drilled into the rock for the purpose, and thus forcibly split it.
- PLUMBING. (Lat. Plumbus.)** The art of casting and working in lead and using it in building. See Book II. Chap. III. Sect. 7.
- PLUMB RULE, PLUMB LINE, or PLUMMET.** An instrument used by masons, carpenters, &c., to draw perpendiculars or verticals, for ascertaining whether their work be upright, horizontal, and so on. The instrument is little more than a piece of lead or plummet at the end of a string, sometimes descending along a wooden or metal ruler raised perpendicularly on another, and then it is called a level. See **LEVEL**.
- PODIUM. (Lat.)** A continued pedestal. A projection which surrounded the arena of the ancient amphitheatre. See **AMPHITHEATRE**.
- POINT. (Lat. Punctum.)** In geometry, according to Euclid, that which has neither length, breadth, nor thickness.
- POINT, ACCIDENTAL.** In perspective, a term used by the old writers on the science to signify the vanishing point.
- POINT OF DISTANCE.** In perspective, the distance of the picture transferred upon the vanishing line from the centre, or from the point where the principal ray meets it, whence it is generally understood to be on the vanishing line of the horizon. See **DISTANCE**.
- POINT, OBJECTIVE.** A point on a geometrical plane whose representation is required on the perspective plane.
- POINT OF SIGHT.** The place of the eye whence the picture is viewed, according to Dr. Brook Taylor, but, according to the old writers on perspective, is what is now called the centre of the picture.
- POINT OF VIEW.** The point of sight.

**POINTED ARCH.** See p. 119, *et seq.*

**POINTED ARCHITECTURE.** See Book I. Chap. II. Sect. 15.

**POINTING.** The raking out the mortar from between the joints of brickwork, and replacing the same with new mortar

**POINTS OF SUPPORT.** The points or surfaces on which a building rests. See p. 438.

**POLISHING.** See **MARBLE.**

**POLLAJOLO.** See **ARCHITECTS**, list of, 179.

**POLLARD.** A tree which has been frequently lopped or *polled* of its head and branches, a practice very injurious to good timber.

**POLYGON.** (Gr. Πόλυς, many, and γωνία, an angle.) A multilateral figure, or one whose perimeter consists of more than four sides and angles. If the sides and angles be equal the figure is called a regular polygon. Polygons are distinguished according to the number of the sides; thus those of five sides are called *pentagons*, those of six, *hexagons*, those of seven, *heptagons*, and so on. The subjoined is a table of the areas and perpendiculars of polygons the side being = 1.

Number of Sides.	Names of Polygons.	Area.	Perpendiculars.
3	Trigon -	·433013	·2886751
4	Tetragon -	1·000000	·5000000
5	Pentagon -	1·720477	·6881910
6	Hexagon -	2·598076	·8660254
7	Heptagon -	3·633912	1·0382617
8	Octagon -	4·828427	1·2071068
9	Enneagon -	6·181824	1·3737387
10	Decagon -	7·694209	1·5388418
11	Endecagon -	9·365640	1·7028437
12	Dodecagon -	11·196152	1·8660254

From the above to find the area of a regular polygon, multiply one of the sides of the polygon by the perpendicular from the centre on that side, and multiply half the product by the number of sides; or, multiply the square of the given side of the polygon by the number opposite to its name under the word area.

**POLYGRAM.** (Gr.) A figure consisting of many lines.

**POLYHÆDRON.** (Gr.) A solid contained under many sides or planes. If the sides of a polyhædron be regular polygons, all similar and equal, it becomes a regular body, and may be inscribed in a sphere, that is, a sphere may be drawn round it, so that its surface shall touch all the solid angles of the body.

**POLYSTYLE.** (Gr. Πόλυς and Στυλος.) Of many columns. See **COLONNADE.**

**POMEL.** (Lat. Pomum.) A globular protuberance terminating a pinnacle, &c.

**PONTOON.** (Fr.) A bridge of boats.

**POORE.** See **ARCHITECTS**, list of, 112.

**POPULAR.** (Lat. Populus.) A tree sometimes used in building. See p. 486.

**PORCH.** (Fr.) An exterior appendage to a building, forming a covered approach to one of its principal doorways.

**PORPHYRY.** (Gr.) A very hard stone, partaking of the nature of granite. It is not so fine as many of the ordinary marbles, but far exceeds them in hardness, and will take a very fine polish. It is still found in Egypt in immense strata. It is generally of a high purple, which varies, however, from claret colour to violet. Its variations are rarely disposed in grains. The red lead coloured porphyry, which abounds in Minorea, is variegated with black, white, and green, and is a beautiful and valuable material. The pale and red porphyry, variegated with black, white, and green, is found in Arabia Petræa and Upper Egypt, and in separate nodules in Germany, England, and Ireland. The sorts best known are what the Italians call the *porfido rosso* (red), which is of a deep red with oblong white spots; the latter are of *feld spath*, which resembles *schorl*. There are two varieties of black porphyry, the *porfido nero*, or black porphyry, and that called the *serpentino nero antico*. The first has a ground entirely black, spotted with oblong white spots like the red porphyry; the other has also a black ground with great white spots, oblong, or rather in the form of a parallelopipedon, nearly resembling in colour what the French call *serpentin vert antique*. The *brown porphyry* has a brown ground with large oblong greenish spots. There are several sorts of green porphyry, which the Italians principally distinguish by the names of *serpentino antico verde*, found in great abundance and in large blocks in the neighbourhood of the ancient Ostia, of a green ground with oblong spots of a lighter shade of the same colour; and the *porfido verde*, which is of a ground of very dark green, almost approaching to black, with lighter shades of a fine grass green. The art of cutting porphyry, as practised by the ancients, appears to be now quite lost.

- PORTAL.** (Fr. *Portail*, from Lat. *Porta*.) The arch over a door or gate; the framework of the gate; the lesser gate, when there are two of different dimensions at one entrance. This term was formerly applied to a small square corner in a room separated from the rest of the apartment by wainscotting.
- PORTCULLIS.** (Fr.) A strong grated framing of timber, resembling a harrow, the vertical pieces whereof were pointed with iron at the bottom, for the purpose of striking into the ground when it was dropped, and also to break and destroy that upon which it fell. It was made to slide up and down in a groove of solid stone-work within the arch of the portals of old castles. Its introduction is supposed to have been in the early Norman castles.
- PORTICO.** (Lat. *Porticus*.) See **COLONNADE**.
- PORTLAND STONE.** A dull white species of stone brought from the island of Portland. See p. 468, *et seq.*
- PORTUGUESE ARCHITECTURE.** See Book I. Chap. II. Sect. 19.
- POSITION.** In geometry, the situation of one thing in regard to another. Speaking architecturally, it is the situation of a building in respect of the four cardinal points of the horizon.
- POST.** (Fr.) An upright piece of timber set in the earth. Any piece of timber whose office is to support or sustain in a vertical direction, as the *king* and *queen posts* in a roof, is so called.
- POST AND PALING.** A close wooden fence constructed with posts fixed in the ground and pales nailed between them. This kind of fence is sometimes called *post and railing*, though this latter is rather a kind of open wooden fence, used for the protection of young quickset hedges, consisting of posts and rails, &c.
- POSTICUM.** (Lat.) See **CELL**.
- POSTSCENIUM OR PARASCENIUM.** (Lat.) In ancient architecture, the back part of the theatre, where the machinery was deposited, and where the actors retired to robe themselves.
- POSTUMIUS, C.** See **ARCHITECTS**, list of, 37.
- POULTRY HOUSE.** A building for the shelter and rearing of poultry, whereof, perhaps, the finest example is that at Winnington in Cheshire. The front is one hundred and forty feet in length, with a pavilion at each end, united to the centre by a colonnade of small cast-iron pillars, supporting a slated roof, which shelters a paved walk. In the centre of the front are four strong columns, and as many pilasters, supporting a slated roof, with an iron gate between them, from which a large semicircular court is entered, with a colonnade round it, and places for the poultry. On one side of the gate is a small parlour, and at the other end of the colonnade a kitchen.
- POWER.** In mechanics, a force which, applied to a machine, tends to produce motion. If it actually produce it, it is called a *moving power*, if not, it is called a *sustaining power*. The term is also used in respect of the six simple machines, viz. the *lever*, the *balance*, the *screw*, the *axis* in *peritrochio*, the *wedge*, and the *pulley*, which are called the *mechanical powers*.
- POZZO, DEL.** See **ARCHITECTS**, list of, 157.
- POZZOLANO.** See **PUZZOLANO**.
- PRÆCINCTIO** (Lat.) or **BALTEUS**. A wide seat, or rather step, round the audience part of the ancient theatres and amphitheatres. It was termed *διαζωμα* by the Greeks.
- PREACHING CROSS.** A cross erected in the highway, at which the monks and others preached to the public.
- PRECEPTORY.** A manor or estate of the knights templars, on which a church was erected for religious service, and a convenient house for habitation, and generally placed under one of the more eminent members of the fraternity, called the *præceptores templi*, to have care of the lands and rents of the place. The preceptories were nothing more than cells to the temple, or principal house of the knights in London.
- PRESBYTERY.** That part of the church reserved for the officiating priests, comprising the choir and other eastern parts of the edifice.
- PRESERVING TIMBER.** See p. 489.
- PRICES OF WORK.** See p. 620, *et seq.*
- PRICE POST.** The same as **QUEEN POST**.
- PRIME.** (Lat.) A figure in geometry that cannot be divided into any other figures more simple than itself, as a triangle in plane figures, and a pyramid in solids.
- A *prime number* is one that cannot be divided by any number without a remainder.
- PRIMING.** In painter's work, the first colouring of the work, which forms a ground for the succeeding coats.
- PRINCIPAL BRACE.** One immediately under the principal rafters, or parallel to them, in a state of compression, assisting, with the principals, to support the timbers of the roof.
- PRINCIPAL POINT.** In perspective, a point in the perspective plane upon which a line will fall drawn from the eye perpendicular to that plane. The principal point is, in fact, the intersection of the horizontal and vertical planes, or the *point of sight*, or of the *eye*.
- PRINCIPAL RAFTERS.** Those whose sizes are larger than the common rafters, and framed in such a manner as to bear the principal weight of the others. See p. 548.

- PRINCIPAL RAY.** In perspective, the line passing from the eye to the principal point on the perspective plane.
- PRIORY.** A building similar in its constitution to a monastery or abbey, the head whereof was called a prior or prioress.
- PRISM.** (Gr. Πρίσμα.) In geometry, an oblong or solid body contained under more than four planes, whose bases are equal, parallel, and similarly situate.
- PRISMOID.** A solid figure, having for its two ends any dissimilar parallel plane figure of the same number of sides, and all the upright sides of the solid trapezoids. If the ends of the prismoid be bounded by dissimilar curves, it is sometimes called a *cylindroid*.
- PRISON.** A building erected for the confinement, or safe custody, of those who have transgressed the laws of their country, until, in due course of time, they are discharged. See Book III. Chap. III. Sect. 18.
- PRIVATE BUILDINGS.** See Book III. Chap. III. Sects. 20, 21, 22.
- PROBLEM.** (Gr.) In geometry, a proposition in which some operation or construction is required, as to divide a line, to make an angle, to draw a circle through three points not in a right line, &c. A problem consists of three parts: the proposition, which states what is required to be done; the resolution or solution, wherein are rehearsed the step or steps by which it is done; and the demonstration, wherein it is shown that by doing the several things prescribed in the resolution the thing required is obtained.
- PRODOMUS.** In ancient architecture, the portico before the entrance to the cell of a temple. See CELL.
- PRODUCING.** In geometry, the continuing a right line to any required length.
- PROFILE.** The vertical section of a body. It is principally used in its architectural sense to signify the contour of architectural members, as of bases, cornices, &c. The profile of an order is in fact the outline of the whole and its parts, the drawing whereof is technically called profiling the order. *Profiles of doors* are given in Book III. Chap. I. Sect. 19.
- PROJECTION.** The art of representing a body on a plane by drawing straight lines through a given point, or parallel from the contour and from the intermediate lines of the body, if any, so as to cut the plane. When the projection is made by drawing straight lines from a point, it is called a *perspective representation*; but if formed by parallel lines, it is called an *orthographical representation*. See PERSPECTIVE, in Book II. Chap. V. Sect. 2., and DESCRIPTIVE GEOMETRY, Book II. Chap. I. Sect. 6. For the method of projecting shadows, see Book II. Chap. IV. Sect. 3.
- PROJECTURE.** An out-jetting or prominence beyond the naked of a wall, column, &c. By the Greeks projectures were called *εκφοράι*, by the Italians *sporti*, by the French *saillés*; so our workmen called them *sailings over*.
- PROLATE.** (Lat.) An epithet applied to a spheroid when generated by the revolution of a semi-ellipsis about its longer diameter.
- PRONAOS.** See CELL.
- PROPORTION.** The just magnitude of each part, and of each part to another, so as to be suitable to the end in view. For the proportions of the several parts of a building, the reader is referred to Book III. Chap. I., wherein they are considered at length.
- PROPORTIONAL COMPASSES.** See COMPASSES.
- PROPORTIONS OF ROOMS.** See Book III. Chap. I. Sect. 25.
- PROPYLÆUM.** (Gr. Προ, before, and Πύλη, a portal.) Any court or vestibule before a building, or before its principal part; but more particularly the entrance to such court or vestibule.
- PROSCENIUM.** (Gr.) That part in the ancient theatre whereon the actors performed in front of the scene, being what we call the stage. The Romans called this part the *pulpitum*.
- PROSTYLE.** (Gr. Προ, and Στυλος, a column.) A portico in which the columns stand in advance of the building to which they belong.
- PROTHYRIS.** (Gr.) A word used in ancient architecture to signify a cross beam or overthwart rafter, as likewise a quoin or course of a wall. See CONSOLE.
- PROTHYRUM.** (Gr.) A porch at the outer door of a house; a portal.
- PROTRACTOR.** (Lat. Protractus.) An instrument for laying down an angle in drawing or plotting.
- PSEUDISODOMUM.** See ISODOMUM.
- PSEUDODIPTERAL or FALSE DIPTERAL.** A disposition in the temples of antiquity wherein there were eight columns in front and only one range round the cell. It is called false or imperfect, because the cell only occupying the width of four columns, the sides from the columns to the walls of the cell have no columns therein, though the front and rear present a column in the middle of the void. See TEMPLE.
- PSEUDOPERIPTERAL or IMPERFECT PERIPTERAL.** A disposition in the ancient temples, in which the columns on the sides were engaged in the wall, and wherein there was no portico except to the façade in front; such are the Maison Carrée at Nismes, and the temple of Fortuna Virilis at Rome.

**PTERA.** See **AISLES.**

**PTEROMA.** (Gr. Πτερον, a wing.) The space between the wall of the cell of a temple and the columns of the peristyle, called also *ambulatio*.

**PUDDLING.** The filling behind a wall, filling up a cavity, or banking up with clay tempered with water, and carefully rammed down with the repeated strokes of beaters or beetles.

**PUGGING.** A coarse kind of mortar laid upon the sound boarding between joists, to prevent the transmission of sound from the apartment above to that below.

**PUG-PIILING.** The same as dovetailed piling, or pile planking.

**PULLEY.** (Fr.) One of the five mechanical powers, consisting of a wheel or rundle, having a channel around it and turning on an axis, serving, by means of a rope which slides in its channel, for the raising of weights. See p. 391.

**PULLEY MORTISE.** The same as **CHASE MORTISE**, which see.

**PULPIT.** (Ital. Pulpito.) An elevated place, an enclosed stage or platform for a preacher in a church. The ancient *ambo* served the same purpose. The pulpits of the present day are generally wretched affairs, and have great affinity in form to sugar hogsheads or rum puncheons with the heads knocked out. The Catholic churches abroad almost invariably furnish fine specimens of carving and composition in their pulpits.

**PULPITUM.** (Lat.) See **PROSCENIUM.**

**PULVINARIA.** (Lat.) Cushions in the ancient temples whereon the statues of the gods were sometimes laid.

**PULVINATED.** See **FRIEZE.**

**PUMP.** See p. 584, 585., where the different pumps for buildings are described.

**PUNCHION.** (Fr. Poinçon.) A name common to iron instruments used in different trades for cutting, incising, or piercing a body. In carpentry it is a piece of timber placed upright between two posts whose bearing is too great, serving, together with them, to sustain some heavy weight. The term is also applied to a piece of timber raised upright under the ridge of a building, and in which are jointed the small timbers. Also to the arbor or principal part of a machine on which it turns vertically, as that of a crane.

**PURBECK STONE.** A species of stone obtained from the island of Purbeck in Dorsetshire, of a very hard texture.

**PURFLED.** (Fr. Pourfiler.) Ornamented work in stone, or other material, representing embroidery, drapery, or lace work.

**PURLINS.** Horizontal pieces of timber lying generally on the principal rafters of a roof to lessen the bearings of the common rafters.

**PUTEAL.** The marginal stone of a well. The celebrated one of Scribonius Libo was erected by order of the senate to mark the spot where a thunderbolt had fallen near the statues of Marsyas and Janus by the Comitia.

**PUTLOGS.** See **LEDGERS.**

**PUTTY.** A sort of paste consisting of whiting, with or without a small portion of white lead, and linseed oil, beaten together until it assumes a kind of tough consistency like dough. In this state it is used by glaziers for fixing in the squares of glass to sash windows, &c., and also by house-painters to stop up holes and cavities in woodwork before painting.

**PUZZOLANA.** A grey-coloured earth deriving its name from Puzzuoli, whence it was originally brought. It is a volcanic matter found in many other parts of Italy, and generally in the neighbourhood of volcanoes active or extinct, from which it has been thrown out in the form of ashes. It immediately hardens when mixed with one-third of its weight of lime and water, forming an admirable water cement. See Book II. Chap. II. Sect. 10.

**PYCNOSTYLE.** (Gr. Πυκνός, close, and Στυλος, column.) See **COLONNADE.**

**PYRAMID.** (Gr. Πυρ, fire.) A solid standing on a square, triangular, or polygonal basis, and terminating at top in a point; or a body whose base is a regular rectilinear figure and whose sides are plain triangles, their several verticals meeting together in one point. It is defined by Euclid as a solid figure consisting of several triangles whose bases are all in the same plane and have one common vertex. When the base of a pyramid is but small in proportion to its height, it is called an *obelisk*. See that word. For some account of the pyramids of Egypt see Book I. Chap. II. Sect 7.

The principal properties of pyramids are as follow: — 1. All pyramids and cones standing on the same base and having the same altitude are equal. 2. A triangular pyramid is the third part of a prism, standing on the same base and of the same altitude. 3. Hence, since every multangular may be divided into triangulars, every pyramid is the third part of a prism standing on the same base and of the same altitude. 4. If a pyramid be cut by a plane parallel to its base, the sections will be similar to the base. 5. All pyramids, prisms, cylinders, &c., are in a ratio compounded of their bases and altitudes; the bases therefore being equal they are in proportion to their altitudes, and the altitudes being equal, they are in proportion to their bases. 6. Similar pyramids, prisms, cylinders, cones, &c., are in a triplicate ratio of their homologous sides. 7.

Equal pyramids, &c., reciprocate their bases and altitudes, *i. e.* the altitude of one is to that of the other, as the base of the one is to the base of the other. 8. A sphere is equal to a pyramid whose base is equal to the surface, and its height to the radius of the sphere.

PYRAMID, FRUSTUM OF A. See FRUSTUM.

PYRAMIDION. The small flat pyramid which terminates the top of an obelisk

PYTHEUS. See ARCHITECTS, list of, 8.

## Q.

QUADRA. (Ital.) A square border of frame round a basso-relievo, panel, &c.; the term is not strictly applicable to any circular border. The term is also applied to the bands or fillets of the Ionic base on each side of the scotia; and also to the plinth or lower member of the podium.

QUADRANGLE. Any figure with four angles and four sides. This term is in architecture in England applied to the inner square or rectangular court of a building, as in the college courts of Oxford, &c.

QUADRANT. (Lat.) The quarter of a circle, or an arc of it containing ninety degrees within its enclosed angle.

QUADRATURE. (Lat.) The determination of the area of a figure in a square, or even any other rectilinear form.

QUADRELS. Artificial stones perfectly square, whence their name, much used formerly by the Italian architects. They were made of a chalky or whitish and pliable earth, and dried in the shade for at least two years.

QUADRIFORES. (Lat.) In ancient architecture folding doors whose height was divided into two parts. When they opened in one height, they were termed *fores valvæ* or *valvæ*.

QUADRILATERAL. In geometry a figure whose perimeter consists of four right lines making four angles, whence it is also called a quadrangular figure.

QUARREL, vulgarly called QUARRY. (Fr. Carré.) A square or lozenge-shaped piece of glass used in lead casements.

QUARRY. (Irish, Carrig.) A place whence stones or slates are procured. The principal stone quarries of England have been given in the body of the work, Book II. Chap. II. Sect. 1. to which place the reader is referred. The slates obtained from the different quarries of the country may be found from the information in Book II. Chap. II. Sect. 8.

QUARRYING. The operation of extracting the produce of a quarry is one which requires much practical knowledge to render it beneficial to the owner of a quarry, but in respect of the particulars whereof this work does not require our notice.

QUARTER GRAIN. See FELT GRAIN.

QUARTER PACE. See FOOT PACE.

QUARTER PARTITION. One consisting of quarters.

QUARTER ROUND. The same as OVULO and ECHINUS, which see, being a moulding whose profile is the quadrant of a circle.

QUARTERING. A series of quarters, as in a partition, &c.

QUARTERFOIL. (Fr. Quatrefeuille.) A modern term denoting a form disposed in four segments of circles, and so called from its imagined resemblance to an expanded flower of four petals. It is only found in the windows, pannels, &c., of Gothic architecture. Mr. Gunn with charming simplicity, not unusual among the amateur writers on Gothic architecture, thinks that the form has no reference to any type in the vegetable kingdom, but that it was originally a representation of the *Greek cross* rounded towards the extremities. If the writings on the subject from the two universities of the country were all put in juxtaposition, they would perhaps afford more scope for mirth than was ever exhibited on any subject.

QUARTERS. Small vertical timber posts, rarely exceeding four by three inches, used instead of walls for the separation or boundary of apartments. They are placed, or ought to be, about twelve inches apart, and are usually lathed and plastered in the internal apartments, but if used for external purposes are commonly boarded.

QUARTZ. (Germ.) A mineral production better known by the name of rock crystal. It includes a variety of stones with which we have nothing here to do, and the only motive for mentioning it is its occurrence in the granites, wherein it is immediately recognised, from its glass-like appearance.

QUAY. (Fr.) A bank formed towards the sea or on the side of a river for free passage, or for the purpose of unloading merchandise.

QUEEN-POST. A suspending post where there are two in a trussed roof.

QUICKLIME. See Book II. Chap. II. Sect. 10.

QUIRK. A piece taken out of any regular ground-plot or floor; thus, if the ground-

plan were square or oblong, and a piece were taken out of the corner, such piece is called a *quirk*.

**QUIRK MOULDING.** One whose sharp and sudden return from its extreme projection to the re-entrant angle seems rather to partake of a straight line on the profile than of the curve. Of this class are a great number of the ancient Greek mouldings.

**QUOINS.** (Fr. Coin.) A term applied to any external angle, but more especially applied to the angular courses of stone raised from the naked of the wall at the corner of a building, and called rustic quoins. See **RUSTIC QUOINS**.

## R.

**RABBIT.** See **REBATE**.

**RABRIUS.** See **ARCHITECTS**, list of, 44.

**RACK.** The case, enclosed by bars, over the manger in a stable, wherein the hay is placed for the horses.

**RADIAL CURVES.** In geometry, those of the spiral kind whose ordinates all terminate in the centre of the including circle, and appear like so many radii of such circle.

**RADIUS.** In geometry, the semidiameter of a circle, or a right line drawn from the centre to the circumference.

**RADIUS OF CURVATURE.** The radius of the osculatory circle at any point in a curve. See **OSCULATORY CIRCLE**.

**RAFFAELLE D'URBINO.** See **ARCHITECTS**, list of, 185.

**RAFTERS.** (Quasi, Roof-trees.) The inclined timbers of a roof, whose edges are in the same plane which is parallel to the covering. The rules and regulations that affect their disposition will be found in p. 544, *et seq.*

**RAGS AND RAG SLATES.** See Book II. Chap. II. Sect. 8.

**RAIL.** (Germ. Riegel.) A term applied in various ways, but more particularly to those pieces of timber or wood lying horizontally, whether between the panels of wainscoting or of doors, or under or over the compartments of balustrades, &c.; to pieces, in framing, that lie from post to post in fences; in short, to all pieces lying in an horizontal direction which separate one compartment from another.

**RAIMOND.** See **ARCHITECTS**, list of, 93.

**RAIN-WATER PIPE.** One usually placed against the exterior of a house to carry off the rain-water from the roof.

**RAISING PIECE.** One which lies under a beam or beams and over the posts or punchions. The term is chiefly used in respect of buildings constructed of timber framework.

**RAKING.** A term applied to any member whose arrisses lie inclined to the horizon.

**RAMP.** (Fr.) In handrails, a concavity on the upper side formed over risers, or over a half or quarter pace, by a sudden rise of the steps above, which frequently occasions a knee above the ramp. The term is also applied to any concave form, as in coping, &c., where a higher is to be joined by a continued line to a lower body.

**RAMPANT ARCH.** One whose abutments or springings are not on the same level.

**RANGE OF RANGING.** (Fr.) A term applied to the edges of a number of bodies when standing in a given plane. Thus, if the edges of the ribs of a groin were placed in a cylindric surface, they would be said to *range*. It is also used in respect of a work that runs straight without breaking into angles.

**RANULPH.** See **ARCHITECTS**, list of, 91.

**RAUL.** See **ARCHITECTS**, list of, 140.

**RATE.** An expression used in the Building Act (see p. 819.) to denote the particular class to which a building belongs, in order to determine the thickness of its walls and mode of building.

**RAY, PRINCIPAL.** In perspective, the perpendicular distance between the eye and the perspective plane.

**REBATE.** (Fr. Rebattre.) A groove or channel cut on a piece of wood, longitudinally, to receive the edge of a body, or the ends of a number of bodies that are to be secured to it. The depth of the channel is equal to the thickness of the body; so that when the end of the latter is let into the rebate, it is in the same face with the outside of the piece.

**REBATE PLANF.** One used for sinking rebates.

**RECESS.** (Lat. Recedo.) A cavity left in a wall, sometimes for use, as to receive a side-board, bed, &c., or to add to the quantity of floor room, and sometimes for ornament, as when formed into a niche, &c.

**RECTANGLE.** In geometry, a figure whose angles are all right angles. Solids are called rectangular with respect to their position, as a cone, cylinder, &c., when perpendicular to the plane of the horizon. A parabola was anciently called a rectangular section of a cone.

- RECTIFICATION.** In geometry, the finding of a right line that shall be equal to a given curve, or simply finding the length of a curve.
- RECTILINEAR.** A figure whose boundaries are right lines.
- REDE.** See ARCHITECTS, list of, 143.
- REDUCT.** A quirk or small piece taken out of a larger to make it more uniform and regular.
- REDUCTION** of a figure, design, or draught, is the copying it on a smaller scale than the original, preserving the same form and proportions. For this purpose a pair of proportional compasses are generally used, by which the labour is much lessened.
- REFECTORY.** (Lat.) A room for taking refreshments. See ABBEY.
- REFLEX.** The light reflected from a surface in light to one in shade.
- REGLET.** (Fr.) A flat narrow moulding, used chiefly to separate the parts or members of compartments or panels from each other, or to form knots, frets, and other ornaments.
- REGRATING.** In masonry, the process of removing the outer surface of an old hewn stone, so as to give it a fresh appearance.
- REGULA.** (Lat.) A band below the tænia in the Doric architrave.
- REGULAR.** An epithet to a figure when it is equilateral and equiangular. A body is said to be regular when it is bounded by regular and equal planes, and has all its solid angles equal.
- REGULAR ARCHITECTURE.** That which has its parts symmetrical or disposed in counter-parts.
- REGULAR CURVES.** The perimeters of conic sections, which are always curved after the same geometrical manner.
- REINS OF A VAULT.** The sides or walls that sustain the arch.
- REJOINTING.** The filling up the joints of stones in old buildings when the mortar has been dislodged by age and the action of the weather.
- RELATION.** The direct conformity to each other, and to the whole, of the parts of a building.
- REMIGIUS.** See ARCHITECTS, list of, 82.
- RENDERING.** The act of laying the first coat of plaster on brickwork.
- REPLUM.** (Lat.) In ancient architecture, the panel of the impages of a framed door.
- REBEDOS.** (Fr. Arriédos.) A screen or division wall placed behind an altar, rood-loft, &c., in old churches.
- RESERVOIR.** (Fr.) An artificial pond, basin, or cistern for the collection and supply of water.
- RESISTANCE.** That power which, acting in opposition to another, tends to destroy or diminish its effect. There are several sorts of resistance, arising from the various natures and properties of the resisting bodies, as the resistance of solids, fluids, air, &c.
- The resistance of solid bodies is the force with which their quiescent parts retain their aggregation. Of it there are two kinds: first, where the resisting and the resisted parts are only contiguous and do not cohere, or, in other words, where they consist of separate bodies or masses. This is by Leibnitz called the *resistance of the surface*, now however called *friction*. Second, where the resisting and resisted parts are not only contiguous, but cohere, that is, are parts of the same continued body or mass. To these may be added the resistance that takes place between surfaces or solids when completely in contact, though not forming the same body, or the resistance they offer to separation. To form a notion of the resistance of the fibres of solid bodies, suppose a cylindrical body suspended vertically by one of its ends. Here the weight of the parts makes them tend downwards and endeavours to separate the body where it is weakest. The parts, however, resist this separation by the force with which they cohere. In this case, then, we see two opposite powers, viz. the weight of the cylinder, which has a tendency to break it, and the force of cohesion to resist fracture. If the base of the cylinder be increased, the length remaining the same, it is manifest that the resistance will increase as the base; but the weight will also increase in the same ratio. Hence, all cylinders of the same matter and length, when vertically suspended, have an equal resistance, whatever their bases. When the length of the cylinder is increased, the base and the resistance remaining the same, the additional weight weakens it, and it will have a greater tendency to break.
- We thus learn what length a cylinder may be so as to break with its own weight, by finding what weight is just sufficient to break another cylinder of the same base and matter; for the required length must be such that its weight may be equal to that of the first, with the additional weight employed to produce the separation.
- If the cylinder be fixed horizontally into a wall, and the rest thence suspended, the weight and resistance will act under different conditions, for if it broke by the action of its weight, the fracture would occur at the end fixed into the wall. In the fracture of the cylinder two forces have acted, and one has overcome the other; that is, the weight of the mass of the cylinder has overcome the resistance arising from the largeness of the base; and as the centres of gravity are points in which all the forces arising from the

weights of the several parts of the same bodies are supposed to be collected, we may conceive the weight of the whole cylinder applied in the centre of gravity of its mass, that is, in a point in the middle of the axis; and the resistance of the cylinder applied in the centre of gravity of its base, it being the base which resists the fracture. If the cylinder breaks with its own weight all the motion is on an immoveable extremity of the diameter of the base, which extremity is the fixed point of a lever, whose arms are the radius of the base and half the axis; hence, the two opposite forces do not only act of themselves and by their absolute, but also by the relative force derived from their distance with regard to the fixed point of the lever.

The weight required to break a body placed horizontally being always less than that required to break it when placed vertically, and being greater or less according to the ratio of the two arms of the lever, the theory is reducible to the finding what part of the absolute weight the relative weight must be, supposing the figure of the body known, which is necessary for finding the centre of gravity. But wherever the centre of gravity falls, the two arms of the lever are estimated accordingly. If the base by which the body is fixed in the wall be not circular, but, for an example, parabolical, and the vertex of the parabola be at top, the motion of the fracture will not be on an immoveable point, but on a whole immoveable line, which may be termed the axis of equilibrium, and it is with regard thereto that the distances of the centres of gravity are to be determined.

A body horizontally suspended, being such that the smallest addition of weight would break it, there is an equilibrium existing between its positive and relative weight; those two opposite powers are consequently to each other reciprocally as the arms of the lever to which they are applied. So, *e converso*, the resistance of a body is always equal to the greatest weight it will sustain, without breaking, in a vertical situation, that is, equal to its absolute weight. If we, therefore, substitute actual weight for the resistance, it follows that the absolute weight of a body suspended horizontally is to its relative weight, as the distance of the centre of gravity from the axis of equilibrium is to the distance of the centre of gravity of its base from the same axis. From this fundamental proposition many consequences are deducible. Thus, if the distance of the centre of gravity of the base from the axis of equilibrium be half the distance of the centre of gravity of the body, the relative weight will only be half the absolute weight.

M. Mariotte having observed that all bodies bend before breaking, considers the fibres as so many little bent springs, never exerting their whole force till stretched to a certain point, and never breaking till entirely unbent. Hence those nearest the axis of equilibrium, which is an immoveable line, are less stretched than the more distant ones, and consequently employ a less part of their force.

The following is a synopsis of the most important results that have been drawn by different writers on the subject, both practical and theoretical:—

1. The resistance of a beam or bar to a fracture by a force acting laterally is as the solid made by a section of the beam in the place where the force is applied, into the distance of its centre of gravity from the point or line where the breach will end.
2. In square beams the lateral strengths are as the cubes of their breadths and depths.
3. In cylindric beams, the resistances or strengths are as the cubes of the diameters.
4. In rectangular beams the lateral strengths are conjointly as the breadths and squares of the depths.
5. The lateral resistances of any beams whose sections are similar figures and alike placed are as the cubes of the like dimensions of those figures.
6. The lateral strength of a beam, with its narrower face upwards, is to its strength with the broader face upwards, as the breadth of the broader face to the breadth of the narrower.
7. The lateral strengths of prismatic beams, of the same materials, are as the areas of the sections and the distance of their centre of gravity directly, and as their lengths and weights reciprocally.
8. When the beam is fixed at both ends, the same property has place, except that in this case we must consider the beam as only half the length of the former.
9. Cylinders and square prisms have their lateral strengths proportional to the cubes of their diameters or depths directly, and their lengths and weights inversely.
10. Similar prisms and cylinders have their strength inversely proportional to their linear dimensions.

The relative resistance of wood and other bodies is shown in the following table:—

	Proportional Resistance.			
Box, yew, plum tree, oak	-	-	-	11
Elm, ash	-	-	-	8½
Walnut, thorn	-	-	-	7½
Red fir, holly, elder, plane, crab-tree, apple-tree	-	-	-	7
Beech, cherry-tree, hazel	-	-	-	6½

						Proportional Resistance.
Alder, asp, birch, white fir, willow	-	-	-	-	-	6
Iron	-	-	-	-	-	107
Brass	-	-	-	-	-	50
Bone	-	-	-	-	-	22
Lead	-	-	-	-	-	6½
Fine freestone	-	-	-	-	-	1

The following table shows the cohesive force of a square inch of different substances from the experiments of Professor Robinson : —

						lbs.
Gold when cast	-	-	-	-	-	20'000
Silver	-	-	-	-	-	40'000
Cast iron	-	-	-	-	40'000 to	60'000
Wrought iron	-	-	-	-	60'000 to	90'000
Soft steel	-	-	-	-	-	12'000
Razor steel	-	-	-	-	-	15'000
Oak and beech in the direction of their fibres from	-	-	-	-	8'000 to	17'000
Willow	-	-	-	-	-	12'000
Fir	-	-	-	-	-	8'000
Cedar	-	-	-	-	-	5'000
Ivory	-	-	-	-	-	16'000
Bone	-	-	-	-	-	5'000
Rope	-	-	-	-	-	20'000

**RESOLUTION OF FORCES.** See p. 381.

**RESSAULT.** (Fr.) The recess or projection of a member from or before another, so as to be out of the line or range with it.

**RETAINING WALLS.** Such as are built to retain a bank of earth from sliding down.

**RETICULATED.** Like the meshes of a net. The *reticulatum opus* of the ancients is described under the article **MASONRY**, which see.

**RETUM.** The continuation of a moulding, projection, &c., in an opposite direction. A side or part which falls away from the front of a straight work.

**RETUM BEAD.** See **BEAD** and **DOUBLE QUIRK**.

**REVEALS.** (Lat. *Revello*.) The vertical sides of an aperture between the front of the wall and the window or door frame.

**REVOLUTION.** In geometry, the motion of a point or line about a centre. Thus a right-angled triangle, revolving round one of its legs as an axis, generates a cone in its revolution.

**RHOMBOID.** (Gr.) A quadrilateral figure whose opposite sides and angles are equal.

**RHOMBUS.** (Gr.) A quadrilateral figure, whose sides are all equal, and whose opposite angles are respectively equal, two being obtuse and two acute.

**RIB.** (Sax.) An arch-formed piece of timber for supporting the lath and plaster work of a vault.

**RIBBING.** An assemblage of ribs for a vault or coved ceiling.

**RIDGE.** (Sax.) The highest part of a roof. The term is more particularly applied to the piece of timber against which the upper end of the rafters pitch.

**RIDGE TILE.** A convex tile made for covering the ridge of a roof.

**RIGA TIMBER.** See p. 484.

**RIGHT ANGLE.** One containing ninety degrees.

**RIGHT CIRCLE.** A circle drawn at right angles with the plane of projection.

**RIGHT LINE.** A line perfectly straight.

**RILIEVO** (It.) or **RELIEF.** The projecture from its ground of any architectural ornament. Among sculptors there are three degrees of rilievo; namely, *alto rilievo*, when the figure stands quite out from its ground; *mezzo rilievo*, when one half of the figure projects; and *basso rilievo*, when the figures are raised from the ground in a small degree.

**RIPLEY.** See **ARCHITECTS**, list of, 283.

**ROD.** A measure of length equal to 16½ feet. A square rod is the usual measure of brick-work, and is equal to 272½ square feet.

**ROD STONE** or **OOLITE.** A kind of limestone, found under chalk in various parts of England. See Book II. Chap. II. Sect. 4.

**ROGER, ARCHBISHOP OF YORK.** See **ARCHITECTS**, list of, 97.

**ROLLS.** Pieces of wood prepared for the plumber to turn over the lead where the sheets join, so as to protect the flat roof or edge from the admission of water. The term also signifies in Gothic architecture mouldings representing bent cylinders.

**ROLLS** or **ROLLERS.** Among workmen are plain cylinders of wood, seven or eight inches diameter and three or four feet long, used for the purpose of moving large stones, beams, and other heavy weights. They are placed successively under the fore part of the masses

to be removed, and at the same time are pushed forward by levers applied behind. When blocks of marble, or other very heavy weights, are to be moved, they use what are called *endless rolls*. These, to give them the greater force and prevent their bursting, are made of wood joined together by cross-quarters, double the length and thickness of the common rollers, and girt with iron hoops at each end. At a foot from the ends are two mortises pierced through and through, into which are put the ends of long levers, which the workmen draw by ropes fastened to the ends, still changing the mortise as the roll has made a quarter of a turn.

**ROMAN ARCHITECTURE.** See Book I. Chap. II. Sect. 13.

**ROMAN ORDER.** The same as **COMPOSITE ORDER**, which see.

**ROMUALDUS.** See **ARCHITECTS**, list of, 71.

**ROOD.** (Sax. Robe.) A cross, crucifix, or figure of Christ on the cross placed in a church.

The *holy rood* was one, generally as large as life, elevated at the junction of the nave and choir, and facing to the western entrance of the church. The *rood loft* was the gallery in which the rood and its appendages were placed. This loft, or gallery, was commonly placed over the chancel screen in parish churches. In Protestant churches the organ now occupies the original place of the rood loft. The *rood tower* or *steeple* was that which stood over the intersection of the nave with the transepts.

**ROOF.** (Sax. Rof, Hpor.) The exterior covering of a building, for whose principles of construction and various sorts the reader is referred to p. 544, *et seq.*

**ROOFING.** The assemblage of timbers, and covering of a roof whose pitch in this climate, for different coverings, is shown in the following table:—

Species of Covering.	Inclination to the Horizon.	Height of Roof in Part of the Span.
Copper or lead	- - 3° 50'	- - one-forty-eighth.
Large slates	- - 22 0	- - one-fifth.
Common slates	- - 26 33	- - one-quarter.
Stone slates	- - 29 41	- - two-sevenths.
Plain tiles	- - 29 41	- - two-sevenths.
Pan tiles	- - 24 0	- - two-ninths.
Thatch	- - 45 0	- - one-half.

**ROOM.** (Sax. Rum.) An interior space or division of a house, separated from the remainder of it by walls or partitions, and entered by a doorway.

**ROOMS, PROPORTIONS OF.** See Book III. Chap. I. Sect. 25.

**ROSE or ROSETTE.** An ornament of frequent use in architectural decorations. The centre of the face of the abacus in the Corinthian capital is decorated with what is called a rose.

**ROSE WINDOW.** A circular window with compartments of mullions and tracery branching from a centre, sometimes called a *catharine wheel* or *marigold window*.

**ROSTRUM.** (Lat.) Literally, the beak of a bird; also the beak or fore-part of a ship; the elevated platform in the Forum of ancient Rome, whence the orators addressed the people, so called from its basement being decorated with the prows of ships. The term is now used generally to signify a platform or elevated spot from which a speaker addresses his audience.

**ROR, DRY.** An extremely destructive disease incident to timber. See p. 490.

**ROTUNDA or ROTONDO.** (Ital.) A building circular on the interior and exterior, such as the Pantheon at Rome. See **CIRCULAR BUILDINGS**.

**ROUGH-CAST.** A species of plastering used on external walls, consisting of a mixture of lime, small shells or pebbles, occasionally fragments of glass and similar materials. This is usually applied to cottages.

**RUDENTURE.** (Lat. Rudis, a rope.) The same as **CABLING**, which see.

**RUDEATION.** (Lat. Ruderatio.) A method of laying pavements, mentioned by Vitruvius, and according to some, of building walls with rough pebbles and mortar. The mortar called *statumen* by Vitruvius was made of lime and sand.

**RUIZ.** See **ARCHITECTS**, list of, 226.

**RULE.** An instrument for measuring short lengths. Of rules there are various sorts, each adapted to the class of artificers for whose use they are made. Thus, there are stone-cutters' rules, masons' rules, carpenters' rules, sliding and parallel rules, &c. The sliding rule is, however, of more general use, as it solves a number of questions from the change of the position of the slider by inspection, and therefore of much importance to the less educated artisan.

**RURAL ARCHITECTURE.** See Book III. Chap. III. Sections 22, 23, and 24.

**RUSSIAN ARCHITECTURE.** Book I. Chap. II. Sect. 20.

**RUSTIC ORDER.** A species of building wherein the faces of the stones are hatched or picked with the point of a hammer.

**RUSTIC QUOINS or COINS.** The stones placed on the external angles of a building projecting

beyond the naked of the wall. The edges are bevelled, or the margins recessed in a plane parallel to the face or plane of the wall.

**RUSTIC WORK.** A mode of building masonry wherein the faces of the stones are left rough, the sides only being wrought smooth where the union of the stones takes place. It was a method much practised at an early period, and re-introduced by Brunelleschi at the revival of the arts. The most common sorts of rustic work are the *frosted*, which has the margins of the stones reduced to a plane parallel to that of the wall, the intermediate parts having an irregular surface; *vermiculated* rustic work, wherein the intermediate parts present the appearance of having been worm-eaten; *chanfered* rustic work, in which the face of the stones being smoothed and made parallel to the surface of the wall, and the angles bevelled to an angle of one hundred and thirty-five degrees, with the face of the stone, where they are set in the wall, the bevel of the two adjacent stones forms an internal right angle.

## S.

**SABLIÈRE.** (Fr.) An obsolete word, signifying a piece of timber as long as a beam, but not so thick.

**SACCHETTI.** See ARCHITECTS, list of, 286.

**SACELLUM.** (Lat.) In ancient Roman architecture, a small inclosed space without a roof. Small *sacella*, too, were used among the Egyptians, attached frequently to the larger temples. In old church architecture, the term signifies a monumental chapel within a church, also a small chapel in a village.

**SACOME.** (Ital.) The exact profile of a member or moulding, applied by the French to the mouldings themselves.

**SACRARIUM.** (Lat.) A small sacred apartment in a Roman house, devoted to a particular deity; also the *cella*, *penetræ* or *adytum* of a temple.

**SACRISTY.** See DIACONICUM.

**SADDLE-BACKED COPING.** See COPING.

**SAG or SAGGING.** The bending of a body by its own weight when resting inclined or horizontally on its ends.

**SAGITTA.** (Lat. an arrow.) A name sometimes applied to the keystone of an arch. In geometry, it is often employed to signify the abscissa of a curve; and in trigonometry it is the versed sine of an arc, which, as it were, stands like a dart upon the chord.

**SAIL OVER.** See PROJECTURE.

**SALIENT.** (Fr.) A term used in respect of a projection of any part or member.

**SALLY.** A projecture. The end of a piece of timber cut with an interior angle formed by two planes across the fibres. Thus the feet of common rafters, and the inclined pieces which support the flying steps of a wooden stair, are frequently cut; as are, likewise, the lower ends of all inclined timbers which rest upon plates or beams.

**SALON or SALOON.** (Fr.) A lofty and spacious apartment, frequently vaulted at top, and usually comprehending the height of two floors with two tiers of windows. Its place is commonly in the middle of a building, or at the head of a gallery, &c. In palaces it is the state room.

**SAN GALLO ANTONIO.** See ARCHITECTS, list of, 199.

**SAN GALLO DI GIUL.** See ARCHITECTS, list of, 178.

**SAN LUCANO.** See ARCHITECTS, list of, 183.

**SAN MICHELL.** See ARCHITECTS, list of, 213.

**SAND.** See Book II. Chap. II. Sect. 10.

**SANDSTONE.** In mineralogy, a stone principally composed of grains, or particles of sand, either united with other mineral substances or adhering without any visible cement. The grains or particles of sandstone are generally quartz, sometimes intermixed with feldspar or particles of slate. When lime is the cementing matter the stone is called calcareous sandstone. The cementing matter is not unfrequently oxide of iron intermixed with alumine. The particles of sand in these stones are of various sizes, some being so small as to be scarcely visible. See Book II. Chap. II. Sect. 1.

**SAP.** The juice or pith of trees that rises from the earth and ascends into the arms, branches, and leaves, to feed and nourish them. Also that part of the stem or wood of the body of a tree that is soft, white, &c. The term is used also as a verb, to denote the undermining a wall by digging a trench under it.

**SAPHETA.** The same as *SOFFITE* or *SOFITE*, which see.

**SARACENIC ARCHITECTURE.** See Book I. Chap. II. Sect. 10.

**SARCOPHAGUS.** (*Σαρξ* flesh, and *φάγω*, to eat.) A tomb or coffin made of one stone. From Pliny it appears to have been originally applied as the name of a stone found in the Troad, which, from its powerful caustic qualities, was selected for the construction of tombs. From its frequent application to this purpose the name became at length used for the tomb itself. Sarcophagi were made of stone, marble, alabaster, porphyry, &c. The Greeks sometimes made them of hard wood, as oak, cedar, or cypress, which resisted

moisture; sometimes of terra cotta, and even of metal. The form was usually a long square, the angle being rounded. The lid varied both in shape and ornament. Those of the primitive Christians often enclosed several corpses, and were ornamented with several sets of bassi rilievi. Those of higher antiquity were frequently sculptured with great taste and beauty of design, the figures being those of the deceased, or parties connected with them, allegorical or mythological. The Egyptian sarcophagi are sculptured with hieroglyphics. Those of the Greeks and Romans sometimes represent Sleep and Death with their legs crossed, one hand supporting the head and the other holding an inverted torch; sometimes Mercury is represented conducting the Souls and Charon ferrying them over in his bark. Occasionally we find on them groups of bacchanals and bacchic scenes.

**SASH.** (Fr. Chas.is, a frame.) A frame for holding the glass of windows, and so formed as to be raised and depressed by means of pulleys. Sashes are single or double hung, or hung with hinges. See p. 572.

**SASH FRAME.** The frame in which the sashes are fitted for the convenience of sliding up and down, or, when hung with hinges, to receive them after the manner of hanging a door.

**SAURUS.** See ARCHITECTS, list of, 34.

**SAW.** (Dutch, *Sawe.*) A tool made of a thin plate of steel, formed on the edge into regular teeth for cutting wood, stone, &c. Saws are of various kinds. See p. 565.

**SAW-PIT.** A pit excavated for sawing timber. The sawing is performed by two persons called *sawyers*, one standing above and the other below. Much of the labour, however, is saved by the use of a saw-mill, or machine moving a circular saw, which by its revolutions and keeping the timber close up, performs the work quicker and better than can be done by the labour just described.

**SAXON ARCHITECTURE.** See Book I. Chap. III. Sects. 1 and 2.

**SAXULPHUS.** See ARCHITECTS, list of, 66.

**SCABELLUM.** (Lat.) A species of pedestal anciently used to support busts or statues. It was high in proportion to its breadth, ending in a kind of sheath, or in the manner of a baluster.

**SCAFFOLD.** (Fr. *Echafaud.*) An assemblage of planks or boards sustained by pieces of wood made fast to vertical poles, and at the other end often resting on the walls, by means whereof the workmen carry up a building, or plasterers complete their work in the interior of houses. On the Continent, scaffolds for public building are much more solidly constructed than in this country.

**SCAGLIOLA.** (Ital.) A species of plaster or stucco invented at Carpi, in the state of Modena, by Guido Sassi, between 1600 and 1649. It is sometimes called *mischia*, from the mixture of colours introduced in it. It was not, however, till the middle of the eighteenth century that the art of making scagliola was brought to perfection. The following is the method of making columns and pilasters:—A wooden cradle, composed of thin strips of deal or other wood is made to represent the column designed, but about  $2\frac{1}{2}$  inches less in diameter than the shaft is intended to be when finished. This cradle is lathed round, as for common plastering, and then covered with a pricking-up coat of lime and hair. When this is quite dry, the scagliola artist commences his operations, and, by imitating the rarest and most precious marbles, produces a work which cannot be, except by fracture or sound, discovered to be counterfeit. The purest gypsum which can be obtained is broken into small pieces, and calcined. As soon as the largest fragments lose their brilliancy, the fire is withdrawn; the calcined powder is passed through a very fine sieve, and mixed up with a solution of Flanders glue, isinglass, &c. In this solution the colours are diffused that are required to be imitated in the marble; but if the work is to be of various colours, each colour is separately prepared, and they are afterwards mingled and combined nearly in the same manner that a painter mixes the primitive colours on his palette to compose his different tints. When the powdered gypsum is prepared and mingled for the work, it is laid on the shaft of the column or other surface over the pricked-up coat of lime and hair, and it is then *float*ed with proper moulds of wood, the artist during the *floating* using the colours necessary for the imitation, by which means they become mingled and incorporated with the surface. The process of polishing follows; and this is done by rubbing the surface with pumice-stone in one of his hands, while with the other he cleans it with a wet stone. It is then polished with tripoli and charcoal and fine and soft linen; and after going over it with a piece of felt dipped in a mixture of oil and tripoli, he finishes with application of pure oil.

**SCALE.** (Sax.) A line divided into a certain number of equal parts, usually on wood, ivory, or metal, for laying down heights and distances in mathematical and architectural drawing. There are various sorts of scales; as, the *plane scale*, *Gunter's scale*, the *diagonal scale*, &c.; but the most generally useful scale is that wherein the objects are drawn some aliquot part of their real size, as a tenth, twelfth, twentieth, twenty-fourth, &c.

**SCALENE TRIANGLE.** (Σκαληνος, oblique.) In geometry, one whose sides are all unequal.

**SCAMILLI IMPARES.** A term used by Vitruvius, which has puzzled all the commentators

It probably signifies certain blocks which serve to raise some of the members of a building, which, from being placed below the level, or below the projection of certain ornaments, might be lost to the eye.

**SCAMILLUS.** A small plinth below the bases of the Ionic and Corinthian columns.

**SCAMMOZZI.** See **ARCHITECTS**, list of, 247.

**SCANDULÆ.** (Lat.) In early buildings of the Romans, shingles or flat pieces of wood used for covering instead of tiles. According to Cornelius Nepos, this was the only covering used in Rome till the war with Pyrrhus in the 470th year of the city.

**SCANTLING.** (Fr.) The dimensions of a piece of timber in breadth and thickness. It is also a term used to denote a piece of timber, as of quartering in a partition, when under five inches square, or the rafter, purlin, or pole plate of a roof. In masonry, scantling is the length, breadth, and thickness of a stone.

**SCAPE** or **SCAPUS.** (Gr.) The shaft of a column; also the little hollow, above or below, which connects the shaft with the base, or with the fillet under the astragal.

**SCAPLING.** A method of tooling the face of a stone.

**SCARFING.** The joining of two pieces of timber by bolting or nailing transversely together, so that the two appear but one. See p. 538.

**SCENE.** (Gr. *Σκηνή*.) Strictly an alley or rural portico for shade or shelter, wherein, according to Cassiodorus, theatrical pieces were first represented. When first applied to a theatre, it signified the wall forming the back of the stage, but afterwards came to mean the whole stage, and is now restricted to the representation of the place in which the drama represents the action. According to Vitruvius, the Greek scene was occupied in the middle by a great door, called the royal door, because decorated as the gate of a palace. At the sides were smaller doors, called *hospitalia*, because representing the entrances to habitations destined for strangers, which the Greeks commonly placed on the two sides of their houses.

**SCENOGRAPHY.** (Gr.) The method of representing solids in perspective.

**SCHEME** of **SCENE ARCH.** One which is a segment of a circle.

**SCHEME.** (Gr.) The representation of any design or geometrical figure by lines so as to make it comprehensible.

**SCHOLIUM.** In mathematics, a remark after the demonstration of a proposition, showing how it may be done some other way, or giving some advice or precaution to prevent mistakes, or adding some particular use or application thereof.

**SCIAGRAPHY** or **SCIOGRAPHY.** (Gr. *Σκία*, a shadow, and *γραφω*, I describe.) The doctrine of projecting shadows as they fall in nature. See Book II. Chap. IV. Sect. 3.

**SCOPAS.** See **ARCHITECTS**, list of, 16.

**SCOTIA.** (Gr. *Σκοτία*, darkness.) The hollow moulding in the base of a column between the fillets of the tori. It receives the name from being so much in shadow. The scotia was, from its resemblance to a pulley, called also *τροχίλος*. It is most frequently formed by the junction of circular areas of different radii, but it ought rather to be profiled as a portion of an ellipsis.

**SCRATCH WORK.** (It. *Sgraffiata*.) A species of fresco with a black ground on which a white plaster is laid, which being scratched off with an iron bodkin, the black appears through the holes, and serves for shadows.

**SCREEN.** (Lat. *Excerno*.) An instrument used in making mortar, consisting of three wooden ledges joined to a rectangular frame at the bottom, the upper part of which frame is filled with wirework for sifting the sand or lime. This term is used in ecclesiastical architecture to denote a partition of wood, stone, or metal, usually so placed in a church as to shut out an aisle from the choir, a private chapel from a transept, the nave from the choir, the high altar from the east end of the building, or an altar tomb from one of the public passages or large areas of the church. In the form and ornamental detail of screens, the ancient artists appear to have almost exhausted fancy, ingenuity, and taste.

**SCREW.** (Dutch, *Scroev*.) One of the six mechanical powers, chiefly used in pressing or squeezing bodies close, though sometimes also in raising weights. See Book II. Chap. I. Sect. 8.

**SCRIBING.** Fitting the edge of a board to a surface not accurately plane, as the skirting of a room to a floor. In joinery, it is the fitting one piece to another, so that the fibres of them may be perpendicular to each other, the two edges being cut to an angle to join.

**SCROLL.** A convolved or spiral ornament variously introduced.

Also the volutes of the Ionic and Corinthian capital. See *fig.*

1046.

*Fig.* 1046.

**SCULLERY.** The apartment for washing up the dishes and utensils wherein the scullion works.

**SCULPTURE.** (Lat. *Sculpo*, to carve.) The art of imitating forms by chiselling and working away solid substances. It is also used to denote the carved work itself. Properly, the word includes works in clay, wax, wood, metal, and stone; but it is generally re-

- stricted to those of the last material, the terms *modelling*, *casting*, and *carving* being applied to the others.
- SEALING.** The fixing a piece of wood or iron on a wall with plaster, mortar, cement, lead, or other binding, for staples, hinges, joints, &c.
- SEASONING TIMBER.** See p. 491.
- SECANT.** (Lat.) A line that cuts another. In trigonometry, the secant is a line drawn to the centre from some point in the tangent, which consequently cuts the circle.
- SECOS.** See **ADYTUM**.
- SECTION OF A BUILDING.** A geometrical representation of it as divided or separated into two parts by a vertical plane, to show and explain the construction of the interior. The section not only includes the parts that are separated, but also the elevation of the receding parts, and ought to be so taken as to show the greatest number of parts, and those of the most difficult construction. Of every building at least two sections should be made at right angles to one another, and parallel to the sides. A section of the flues should also be made, in order to avoid placing timbers near them.
- SECTION OF A SOLID.** The plane of separation dividing one part from the other. It is understood to be always a plane surface.
- SECTOR.** An instrument for measuring or laying off angles, and dividing lines and circles into equal parts.
- SECTOR OF A CIRCLE.** The space comprehended between two radii and the arc terminated by them.
- SEGMENT.** (Lat.) A part cut off from anything. The area contained by the arc of a circle and a chord. In the segment of a circle the chord of the arc is called the base of the segment, and the height of the arc the height of the segment.
- SEGMENT OF A SPHERE.** A portion cut off by a plane in any part except the centre, so that the base of such segment must be always a circle, and its surface a part of the sphere.
- SELL.** See **CILL** and **APERTURE**.
- SEMICIRCLE.** The half of a circle contained by the diameter and circumference.
- SEMICIRCULAR ARCHES.** Those whose arcs are semicircular.
- SENNAMAR.** See **ARCHITECTS**, list of, 55.
- SEPULCHRE.** (Lat. Sepelire, to bury.) A grave, tomb, or place of interment. The *cenotaph* was an empty sepulchre raised in honour of a person who had had no burial.
- SERAGLIO.** (Pers. Serai.) A large hall or house. The palace of an eastern prince, but more particularly that in which the females are lodged.
- SERLIO.** See **ARCHITECTS**, list of, 238.
- SERPENTINE.** See **PORPHYRY**.
- SERVANDONI.** See **ARCHITECTS**, list of, 288.
- SESSPOOL.** See **CESSPOOL**.
- SETT.** In piling, a piece placed temporarily on the head of a pile which cannot be reached by the monkey or weight from some intervening matter.
- SETTING.** The hardening of cement. The term is also used in masonry for fixing stones in walls or vaults, in which the greatest care should be taken that the stones rest firmly on their beds, and that their faces be ranged in the proper surface of the work.
- SETTING-OUT ROD.** One used by joiners for setting-out frames, as of windows, doors, &c.
- SETTLEMENTS.** Those parts in which failures by sinking in a building have occurred.
- SETT-OFF.** The projecting part between the upper and lower portion of a wall where it diminishes in thickness.
- SEVERUS.** See **ARCHITECTS**, list of, 43.
- SEVERY.** A compartment or division of scaffolding. It is also a separate portion or division of a building corresponding with the modern term compartment, being as it were severed or divided.
- SEWER.** A drain or conduit for carrying off soil or water from any place. See Book II. Chap. III. Sect. I.
- SEXAGESIMAL.** The division of a line, first into sixty parts, then each of these again into sixty, and so on, as long as division can be made. It is principally used in dividing the circumference of a circle.
- SHADOWS AND SHADOWING.** In drawing, the art of correctly casting the shades of objects and representing their degrees of shade. See Book II. Chap. IV. Sect. 3.
- SHAFT.** (Sax. Sceapt.) The cylindrical part, or rather body, of a column, between the base and the capital. It is, properly, the frustum of a conoid, and is also called the *fust*, *trunk*, or body of the column.
- SHAFT OF A CHIMNEY.** See **CHIMNEY**.
- SHAFT OF A KING POST.** The part between the *joggles*.
- SHAKE.** A fissure or rent in timber by its being dried too suddenly, or exposed to too great heat. Any timber when naturally full of slits or clefts is said to be *shaky*.
- SHANKS.** (Sax.) The space between two channels of the Doric triglyph, sometimes called the legs of the triglyph. The ancients called the *shank femur*.

**SHEET LEAD.** See Book II, Chap. III, Sect. 7.

**SHELF.** (Sax.) A board fixed against a wall by its edge, the upper side being horizontal, for receiving whatever may be placed upon it. A shelf is usually supported by brackets, or by pieces at the end, called *standards*.

**SHINGLES.** (Germ. Schindel.) Small oaken boards used like slates for covering a building, from eight to twelve inches long, and about four inches broad, thicker on one edge than the other. The process of making a roof of this kind is called *shingling*.

**SHOE.** The inclined piece at the bottom of a water trunk or lead pipe for turning the course of the water, and discharging it from the wall of a building.

**SHORE or SHOAR.** (Sax.) A prop or oblique timber acting as a brace on the side of a building, the upper end resting against that part of the wall upon which the floor is supported, and both ends received by plates or beams. A *dead shore* is an upright piece built up in a wall that has been cut or broken through for the purpose of making some alterations in the building.

**SHOOTING.** Planing the edge of a board straight, and out of winding.

**SHOOTING BOARDS.** Two boards joined together, with their sides lapped upon each other, so as to form a rebate for making short joints.

**SHOULDER OF A TENON.** The plane transverse to the length of a piece of timber from which the tenon projects. It should be at right angles to the length, though it does not always lie in the plane as here defined, but sometimes in different planes.

**SHREAD HEAD.** The same as **JERKIN HEAD**, which see.

**SHREDDINGS or FURRINGS.** In old buildings, short slight pieces of timber fixed as bearers below the roof, forming a straight line with the upper side of the rafters.

**SHRINE.** (Sax. Scyn.) A desk or cabinet; a case or box, particularly one in which sacred things are deposited: hence applied to a reliquary and to the tomb of a canonised person. The altar is sometimes called a shrine, and in this case its form and condition, and the annexation of a statue to it, was of importance, because such tombs had greater privileges than plainer monuments.

**SHRINKING.** The contraction of a piece of timber in its breadth by seasoning, hot water, &c. It is proportional to its breadth, the length not changing. Hence in unseasoned timber mitred together, such as the architraves of doors and windows, the mitres are always close on the outside and open to the door, forming a wedge-like hollow on each side of the frame. It is to avoid the effects of shrinking that narrow boards called *battens* are used in floors.

**SHUTE.** See **ARCHITECTS**, list of, 243.

**SHUTTERS.** The boards which shut up the aperture of a window. See **BOXINGS OF A WINDOW**.

**SIDE POSTS.** Truss posts placed in pairs, disposed at the same distance from the middle of the truss. Their use is not only to support the principal rafters, &c., but to suspend the tie beam below. In extended roofs two or three pair of side posts are used.

**SIDE TIMBERS or SIDE WAVERS.** The same as purlins, the first term being used in Somersetshire and the last in Lincolnshire.

**SIENTITE.** See **SVENITE**.

**SILL.** See **CILL** and **APERTURE**.

**SILOK.** See **ARCHITECTS**, list of, 211.

**SILT.** The muddy deposit of standing water.

**SIMA.** See **CYMA**.

**SIMILAR FIGURES.** Those whose several angles are respectively equal, and the sides about the equal angles proportional.

**SIMONETTI.** See **ARCHITECTS**, list of, 296.

**SINE.** A right line drawn from one end of an arch perpendicular upon the diameter, or it is half the chord of twice the arch. The sine of the complement of an arch is the sine of what the arch wants of ninety degrees. The *versed sine* is that part of the diameter comprehended between the arc and the sine.

**SINGLE FRAME and NAKED FLOOR.** One with only one tier of joists.

**SINGLE HUNG.** An arrangement in a pair of window sashes, in which one only is movable.

**SINGLE JOISTS FLOOR.** One without binding joists.

**SINGLE MEASURE.** A term applied to a door that is square on both sides. *Double measure* is when the door is moulded on both sides. When doors are moulded on one side and are square on the other, they are accounted measure and half.

**SSISSVERNE.** See **ARCHITECTS**, list of, 101.

**SITE.** (Lat. Situs.) The situation of a building; the plot of ground on which it stands.

**SKEW BACK.** In a straight or curved arch, that part of it which recedes beyond the springing from the vertical line of the opening.

**SKIRTING or SKIRTING BOARD.** The narrow board placed round the margin of a floor, which, where there is a dado, forms a plinth for its base; otherwise, it is a plinth for the

- room itself. Skirting is either scribed close to the floor or let into it by a groove; in the former case a fillet is put at the back of the skirting to keep it firm.
- SKIRTS.** Several superficies in a plane, which would cover a body when turned up or down without overlapping.
- SKREEN.** See **SCREEN.**
- SKYLIGHT.** A frame consisting of one or more inclined planes of glass, placed in a roof to light passages or rooms below.
- SLAB.** An outside plank or board sawed from the sides of a timber tree, and frequently of very unequal thickness. The word is also used to express a thin piece of marble, consisting of right angles and plane surfaces. See **CHIMNEY.**
- SLATE.** See Book II. Chap. II. Sect. 8.
- SLATERS' WORK.** See Book III. Chap. II. Sect. 6.
- SLEEPERS.** Horizontal timbers disposed in a building next to the ground transversely under walls, ground joists, or the boarding of a floor. When used on piles they are laid upon them, and planked over to support the superincumbent walls. Underground joists either lie upon the solid earth, or are supported at various parts by prop stones. When in the former position, having no rows of timber below, these ground joists are themselves called sleepers. Old writers on practical architecture call those rafters lying in the valley of a roof, sleepers; but in this sense the word is now obsolete.
- SLIDING RULE.** One constructed with logarithmic lines, so that by means of another scale sliding on it, various arithmetical operations are performed merely by inspection.
- SLIT DEAL.** See **BOARD.**
- SLUCE.** A stop against water for the drainage or supply with water of a place. It is hung with hinges from the top edge when used merely as a stop against the water of a river; but when made for supply as well, it moves vertically in the groove of its frame by means of a winch, and is then called a penstock.
- SMITHERY and IRONMONGERY.** See Book II. Chap. III. Sect. 10.
- SMOOTHING PLANE.** See p. 364.
- SNACKET.** A provincial term for the hasp of a casement.
- SNIPE'S BILL PLANE.** One with a sharp arris for getting out the quirks of mouldings.
- SOANE.** See **ARCHITECTS**, list of, 316.
- SOCKET CHISEL.** A strong tool used by carpenters for mortising, and worked with a mallet.
- SOCLE or ZOCLE.** A square member of less height than its horizontal dimension, serving to raise pedestals or to support vases or other ornaments. The socle is sometimes continued round a building, and is then called a *continued socle*. It has neither base nor cornice.
- SOFFITA, SOFFIT, or SOFITE.** (Ital.) A ceiling; the lower surface of a vault or arch. A term denoting the under horizontal face of the architrave between columns; the under surface of the corona of a cornice.
- SOILS.** A provincial term, chiefly, however, used in the north, signifying the principal rafters of a roof.
- SOLDER.** A metallic composition used in joining together or *soldering* metals.
- SOLID.** (Lat.) In geometry, a body which has length, breadth, and thickness; that is, it is terminated or contained under one or more plane surfaces, as a surface is under one or more lines. Regular solids are such as are terminated by equal and similar planes, so that the apex of their solid angles may be inscribed in a sphere.
- SOLID ANGLES.** An angle formed by three or more angles in a point, and whereof the sum of all the plane angles is less than three hundred and sixty degrees, otherwise they would constitute the plane of a circle and not of a solid.
- SOLID SHOOT.** See **WATER SHOOT.**
- SOLVE.** The French term for a joist, rafter, or piece of wood, either slit or sawed, with which builders lay their ceilings. The term is rarely used in the English language.
- SOMMERING.** See **SUMMERING.**
- SORTANT ANGLE.** The same as **SALIENT ANGLE**, which see.
- SOSTRATUS.** See **ARCHITECTS**, list of, 25.
- SOUFFLOT.** See **ARCHITECTS**, list of, 299.
- SOUND-BOARD.** The same as a canopy or type over a pulpit, to reverberate the voice of the speaker.
- SOUND-BOARDING.** In floors, consists of short boards placed transversely between the joists, and supported by fillets fixed to the sides of the latter for holding pugging, which is any substance that will prevent the transmission of sound from one story to another. The narrower the sound-boards the better. The fillets on which they rest may be about three-quarters of an inch thick and about an inch wide, nailed to the joists at intervals of a foot. See **BOARDING FOR PUGGING.**
- SOUSE (Fr.) or SOURCE.** A support or under-prop.
- SPAN.** An imaginary line across the opening of an arch or roof, by which its extent is estimated.

**SPAN ROOF.** One consisting of two inclined sides, in contradistinction to *shed* or *leanto* roofing. It may be with simple rafters, with or without a collar beam, or when of increased span it may be trussed, the term only applying to the external part.

**SPANDEL.** The irregular triangular space between the outer curve or extrados of an arch, a horizontal line from its apex, and a perpendicular line from its springing.

**SPANDEL BRACKETING.** A cradling of brackets fixed between one or more curves, each in a vertical plane, and in the circumference of a circle whose plane is horizontal.

**SPANISH ARCHITECTURE.** See Book I. Chap. II. Sect. 19.

**SPAR-PIECE.** A name given in some places to the collar beam of a roof.

**SPARS.** The common rafters of a roof for the support of the tiling or slating.

**SPECIFICATION.** A description at length of the materials and workmanship to be used and employed in the erection of any building. See Book II. Chap. III. Sect. 13.

**SPECIFIC GRAVITY.** A gravity or weight of every solid or fluid compared with the weight of the same magnitude of rain water, which is chosen as the standard of comparison, on account of its being subject to less variation in different circumstances of time, place, &c., than any other solid or fluid. By a fortunate coincidence, at least to the English philosopher, it happens that a cubic foot of rain water weighs 1000 ounces avoirdupois; consequently, assuming this as the specific gravity of rain water, and comparing all other bodies with this, the same numbers that express the specific gravity of bodies will at the same time express the weight of a cubic foot of each in avoirdupois ounces, which affords great facility to numerical computations. Hence are readily deduced the following laws of the specific gravity of bodies:—

1. In bodies of equal magnitudes the specific gravities are directly as the weights or as their densities. 2. In bodies of the same specific gravities the weights will be as the magnitudes. 3. In bodies of equal weights the specific gravities are inversely as the magnitudes. 4. The weights of different bodies are to each other in the compound ratio of their magnitudes and specific gravities.

Thus it is obvious, that if of the magnitude, weight, and specific gravity of a body any two be given, the third may be found; and we may thus arrive at the magnitude of bodies which are too irregular to admit of the common rules of mensuration; or, by knowing the specific gravity and magnitude, we may find the weight of bodies which are too ponderous to be submitted to the action of the balance or steel yard; or, lastly, the magnitude and weight being given, we may ascertain their specific gravities.

#### TABLE OF SPECIFIC GRAVITIES

(Extracted from Davies, Lavoisier, Young, and other authentic sources).

*Note.*—Water at 60° is assumed 1000 specific gravity.

**SPECUS.** (Lat.) In ancient architecture, the canal into which the water flowed in aqueducts raised above the surface of the ground, and constructed of hewn stones or bricks. It was covered with a vault to preserve the water from the sun, and from being mixed with rain water. The specus was sometimes covered with flat stones, laid horizontally, as in the Aqua Martia, part of the Aqua Claudia, and the aqueduct of Segovia. Sometimes the same arcade carried several of these canals one above the other.

**SPHÆRISTERIUM.** A building for the exercise of the ball; a tennis court. The ancients generally placed sphæristeria among the apartments of their baths and gymnasia. They were also placed in large villas, as in those of Pliny the younger.

**SPHERE.** (Gr. *Σφαῖρα*.) A solid, whose surface is at every point equally distant from a certain point within the solid, which point is called the *centre of the sphere*. Every sphere is equal to two-thirds of its circumscribing cylinder, that is, it is equal to a cylinder whose ends are circles, equal to a great circle of the sphere, and whose height is equal to the diameter of the same.

**SPHERICAL BRACKETING.** That so formed that the surface of the plastering which it is to receive forms a spherical surface.

**SPHEROID.** See CONOID.

**SPHEROIDAL BRACKETING.** That formed to receive the plastering of a spheroid.

**SPINA.** See CIRCUS.

**SPINTHARUS.** See ARCHITECTS, list of, 9.

**SPIRAL.** A curve which makes one or more revolutions round a fixed point, and does not return to itself.

**SPIRE.** (Gr. *Σπῆρα*, a twisting.) In ancient architecture, the base of a column, and sometimes the astragal or torus; but among the moderns it designates a steeple diminishing as it ascends, either pyramidally or conically. See ADDENDA to Glossary.

**SPLAYED.** A term applied to whatever has one side making an oblique angle with the other: thus, the heading joists of a boarded floor are frequently splayed in their thickness; as are also the jambs or sides of a window. In the latter case, the practice is for the better lighting of a room. The word *fluing* is sometimes applied to an aperture, in the same sense as *splayed*.

**SPRING BEVEL OF A RAIL.** The angle made by the top of the plank, with a vertical plane touching the ends of the railpiece, which terminates the concave side.

**SPRINGED.** In boarding a roof, the setting the boards together with bevel joints, for the purpose of keeping out the rain.

**SPRINGER.** The impost or place where the vertical support to an arch terminates, and the curve of the arch begins; the term is sometimes used for the *rib* of a groined roof.

**SPRINGING COURSE.** The horizontal course of stones, from which an arch springs or rises; or that row of stones upon which the first arch stones are laid.

**SQUARE.** (Lat. *Quadrā*.) A figure of four equal sides, and as many equal angles; also, an area of such form surrounded by houses, and ornamented in the centre with a lawn, shrubs, trees, &c. In joinery, a work is said to be *square framed*, or *framed square*, when the framing has all the angles of its styles, rails, and mountings square without being moulded. The word is also applied to an instrument for setting out angles square. See CARPENTER'S SQUARE.

It is also a measure used in building of 100 superficial feet.

**SQUARE SHOOT.** A wooden trough for discharging water from a building.

**SQUARE STAFF.** A piece of wood placed at the external angle of a projection in a room to secure the angle, which if of plaster would be liable to be broken, and at the same time to allow a good finish for the papering.

**SQUARING A HANDRAIL.** The method of cutting a plank to the form of a rail for a staircase, so that all the vertical sections may be right angles.

**SQUARING A PIECE OF STUFF.** The act of trying it by the square, to make the angles right angles.

**STABLE.** (Lat.) A building for the accommodation of horses.

**STACK OF CHIMNEYS.** See CHIMNEY.

**STADIUM.** (Gr.) In ancient architecture, an open space wherein the *athletæ* or wrestlers exercised running, and in which they contested the prizes. It signifies also the place itself where the public games were celebrated, often formed a part of the gymnasia. The word also denotes a measure of length among the Grecians, of 125 paces.

**STAFF-BEAD.** See ANGLE-BEAD.

**STAGE.** A floor or story. In a theatre, the floor on which the performers act. The stage of a buttress is, in ecclesiastical architecture, the part between one splayed projection and the next.

**STAIR.** (Sax. *Stæger*, to step.) A stone, or piece of other material, by which a person raises himself one step. A series of steps or stairs for ascending from the lower to the upper part of a building, when enclosed by a wall, is called a staircase.

**STAIRCASE.** That part or subdivision in a building containing the stairs, which enable persons to ascend or descend from one floor to another. See Book III. Chap. I. Sect. 23. for its construction.

**STALK.** (Sax.) An ornament in the Corinthian capital, which is sometimes fluted, and resembles the stalk of a plant; from it spring the volutes and helices.

**STALL.** (Sax.) A place or division in a stable wherein one horse is placed for feeding and sleeping. According to their number in a stable it is called a one-stall, two-stall, &c. stable. This word is also used to denote an elevated seat in the choir or chancel of a church appropriated to an ecclesiastic, such as the prebendal stall of a cathedral.

**STANCHION.** (Fr. Estanton.) A prop or support. The upright mullions or bars of a window or open screen. Also a **PUNCHION**, which see.

**STANDARDS.** The upright pieces in a plate rack, or above a dresser, to support the shelves thereover.

When the edges of standards are cut into mouldings across the fibres of the wood they are called *cut standards*.

**STAPLE.** A small piece of iron pointed at each end, and bent round, so that the two ends may be parallel to each other, and of equal lengths, to be driven into wood or into a wall, thus forming a loop for fastening a hasp or bolt.

**STARLINGS OR STERLINGS**, sometimes called **STILTS**. An assemblage of piles driven round the piers of a bridge to give it support.

**STATICS.** See **MECHANICS**.

**STATUARY MARBLE.** See Book II. Chap. II. Sect. 3.

**STAVES.** Small upright cylinders, sometimes called *rounds*, for forming a rack to contain the hay in stables for the supply of it to the horses.

**STAY.** A piece performing the office of a brace, to prevent the swerving of the piece to which it is applied. The term is general, and applies to all materials.

**STEEL.** (Sax. Stal.) Iron united with carbon, which is accomplished in two ways, by fusion and by cementation; the former is used to convert iron into steel immediately from the ore, or from crude or cast-iron; the last-named process is effected by exposing iron, covered with charcoal, to a strong continued heat. The process for converting iron into steel was known to the ancients.

**STRENGTH.** The brickwork laid dry (that is, without mortar) used for forming the cylindrical shaft of a well or cesspool, whose office is to prevent the irruption of the surrounding soil.

**STEEPLE.** (Sax. Scipel.) A lofty erection attached to a church, chiefly intended to contain its bells. The word is a general term, and applies to every appendage of this nature, whether tower or spire, or a combination of the two.

**STEPS.** The same as **STAIR**, which see.

**STEREOBATA.** See **PEDESTAL**.

**STEREOGRAPHIC PROJECTION.** That projection of the sphere wherein the eye is supposed to be placed on the surface.

**STEREOGRAPHY.** (Gr. *Στερεος*, solid, and *Γραφω*, I describe.) That branch of solid geometry which demonstrates the properties and shows the construction of all regularly defined solids; it explains the methods for constructing the surfaces on planes, so as to form the entire body itself, or to cover its surface; or, when the solid is bounded by plane surfaces, the inclination of the planes.

**STEREOTOMY.** The science of cutting solids to suit certain conditions required for their forms.

**STILE.** (Sax.) The vertical part of a piece of framing into which, in joinery, the ends of the rails are fixed by mortises and tenons.

**STILTS.** See **STARLINGS**.

**STOA.** (Gr.) In Grecian architecture, a term corresponding with the Latin *porticus*, and the Italian *portico*.

**STOCK.** The part of a tool for boring wood with a crank whose end rests against the breast of the workman, while with one hand he holds the boring end steady, and with the other turns the crank; the steel borers are called *bits*, and the whole instrument is called a *stock and bit*.

**STONE.** (Sax.) A natural indurated substance found beneath and on the surface of the earth in almost every part of the world, and which for its strength and durability has been universally employed for building purposes. See Book II. Chap. II. Sect. 1.

**STOOTHINGS.** A provincial term which signifies the battening of walls.

**STOP-COCK.** A cock used in plumbery to turn off the supply to a reservoir.

**STORY.** (Lat. or Sax. *Stop.*) One of the vertical divisions of a building; a series of apartments on the same level.

**STORY POSTS.** Upright timbers disposed in the story of a building for supporting the superincumbent part of the exterior wall through the medium of a beam over them; they are chiefly used in sheds and workshops, and should have either a solid wall below or stand upon a strong wooden sill upon inverted arches, or upon large stones, with their ends let into sockets.

**STORY ROD.** One used in setting up a staircase, equal in length to the height of the story,

- and divided into as many parts as there are intended to be steps in the staircase, so that they may be measured and distributed with accuracy.
- STRAIGHT JOINT FLOOR.** See **FLOOR.**
- STRAIN.** (Sax. *Scpeug.*) The force exerted on any material tending to disarrange or destroy the cohesion of its component parts.
- STRAINING PIECE OR STRUTTING PIECE.** A beam placed between two opposite beams to prevent their nearer approach, as rafters, braces, struts, &c. If such a piece serves also the office of a sill, it is called a *straining sill*.
- STRAP.** (Dutch, *Stroppe.*) An iron plate for the connection of two or more timbers, whereinto it is screwed by bolts.
- STRENGTH OF MATERIALS.** See Book II. Chap. I. Sect. 11.
- STRETCHED OUT.** A term applied to a surface that will just cover a body so extended that all its parts are in a plane, or may be made to coincide with a plane.
- STRETCHER.** A brick or stone laid with its longer face in the surface of the wall.
- STRETCHING COURSE.** In walling, a course of stones or bricks laid with their longer dimensions in a horizontal line parallel to the face of the wall; it is exactly the contrary of a *heading course*, in which the breadths of the stones or bricks are laid in a straight line parallel to the face of the wall.
- STRILE.** (Lat.) The lists or fillets between the flutes of columns.
- STRIATED.** Champered or channeled.
- STRIGES.** The channels of a fluted column.
- STRIKING.** A term used to denote the draught of lines on the surface of a body; the term is also used to denote the drawing of lines on the face of a piece of stuff for mortises, and cutting the shoulders of tenons. Another application of the word occurs in the practice of joinery, to denote the act of running a moulding with a plane. The *striking of a centre* is the removal of the timber framing upon which an arch is built, after its completion.
- STRING OR STRING PIECE.** That part of a flight of stairs which forms its ceiling or sofit.
- STRING BOARD.** In wooden stairs, the board next the well-hole which receives the ends of the steps; its face follows the direction of the well-hole, whatever the form: when curved, it is frequently formed in thicknesses glued together, though sometimes it is got out of the solid, like a hand-rail.
- STRIX.** (Lat.) A channel in a fluted column.
- STRUCK.** A term used to denote the removal of any temporary support in a building during its execution.
- STRUT.** See **BRACE.**
- STRUTTING BEAM OR STRUT BEAM.** A term used by old writers in carpentry, for what is now called a *straining or collar beam*.
- STRUTTING PIECE.** The same as **STRAINING PIECE**, which see; and also **BRIDGINGS** and **KEYS**.
- STUCCO.** (Fr. *Stuc.*) A term indefinitely applied to calcareous cements of various descriptions.
- STUDS.** (Sax.) The quarters or posts in partitions. The term is used chiefly in the provinces.
- STUFF.** (Dutch.) A general term for the wood used by joiners.
- STYLOBATA.** See **PEDESTAL**.
- SUBDIVISION AND APARTMENTS OF A BUILDING.** See Book III. Chap. II. Sect. 5.
- SUBNORMAL.** The distance between the foot of the ordinate and a perpendicular to the curve (or its tangent) upon the axis.
- SUB-PLINTH.** A second and lower plinth placed under the principal one in columns and pedestals.
- SUB-PRINCIPALS.** The same as auxiliary rafters or principal braces.
- SUDATIO.** (Lat.) See **CONCAMERATA SUDATIO**.
- SUGER.** See **ARCHITECTS**. list of, 96.
- SUMMER.** (Perhaps from Soma, Ital.) The lintel of a door, window, &c. A beam tenoned into a girder to support the ends of joints on both sides of it. It is frequently used as a synonyme for a girder. Also a large stone laid over columns and pilasters in the commencement of a cross vault. It is, moreover, used in the same sense as **BRESSUMMER**, which see.
- SUMMER TREE.** See **DORMANT TREE**.
- SUMMERING.** See **BEDS OF A STONE**.
- SUNK SHELVES.** Such as are formed with a groove in them to prevent the plates, dishes, or other materials sliding off their upper surface.
- SUPERSTRUCTURE.** (Lat.) The work built on the foundation of a building. The upper part.
- SUPPORT.** See **POINTS OF SUPPORT**.
- SURBASE.** The series of mouldings immediately above the base of a room.
- SWALLOW-TAILED.** See **DOVE-TAILED**.
- SWEDISH TIMBER.** See p. 485.

- SYCAMORE.** The *acer pseudo-platanus*, a tree, whose wood is much used by turners. See p. 486.
- SYENITE.** A stone which consists of feldspar and hornblende, of various colours, as reddish, dull green, &c., as the feldspar or hornblende may predominate. It obtained the name from its abundance of syene, and according to Pliny was at first named *pyropæcilos*. It is, in fact, a species of granite, and was the material used for Pompey's Pillar.
- SYMMETRY.** (Gr. *Συμ*, with, and *Μετρον*, I measure.) A system of proportion in a building, from which results from one part the measurement of all the rest. It also conveys the meaning of uniformity as regards the answering of one part to another.
- SYSTYLE.** (Gr.) See COLONNADE.

## T.

- TABERN.** A provincial term for a cellar.
- TABERNACLE.** (Lat.) In Catholic churches the name given to a small representation of an edifice placed on the altar for containing consecrated vessels, &c.
- TABLE.** In perspective, the same as the plane of the picture, being the paper or canvas on which a perspective drawing is made, and usually perpendicular to the horizon. In the theory of perspective, it is supposed to be transparent for simplifying the theory.
- TABLE or TABLET.** (Lat. *Tabula*.) A flat surface generally charged with some ornamental figure. The outline is generally rectangular, and when raised from the naked of the wall, is called a *projecting or raised table*. When not perpendicular to the horizon, it is called a *raking table*. When the surface is rough, frosted, or vermiculated, from being broken with the hammer, it is called a *rusticated table*.
- TABLE, CORBEL.** See CORBEL TABLE.
- TABLE OF GLASS.** In glass works and among glaziers, a circular plate of glass, being its original form before it is cut or divided into squares. Twenty-four tables make a *case*.
- TABLE, WATER.** An inclined plane where a wall sets off to a smaller projection, for the purpose of throwing off the water, principally used in buttresses and other parts of Gothic edifices.
- TABLET.** The same as TABLE.
- TABLING.** A term used by the Scotch builders to denote the coping of the walls of very common houses.
- TABLINUM.** (Lat.) In Roman architecture, an apartment situated in the narrow part of the atrium, as is supposed, fronting the entrance. Its exact position is not now known, and indeed the situation of it may, under circumstances, have varied, its true place therefore must be a matter of doubt.
- TABULATUM.** (Lat.) A term used by the Romans not only in respect to the floors, wainscottings, ceilings, &c., which were constructed of wood, but also to balconies and other projecting parts, which latter Vitruvius calls *projectiones*.
- TACKS.** Small nails used for various purposes, but principally for stretching cloth upon a board.
- TÆNIA.** (Gr.) The fillet which separates the Doric frieze from the architrave.
- TAIL.** (Verb.) A term denoting the hold of any bearing piece on that which supports it, as where the end of a timber lies or *tails* upon the wall. The expression is similar to what in joinery is called *housing*, with this difference, that housing expresses the complete surrounding of the cavity of the piece which is let in.
- TAIL BAYS.** See CASE BAYS.
- TAIL TRIMMER.** One next the wall, into which the ends of joints are fastened, in order to avoid flues.
- TAILING.** The part of a projecting stone or brick inserted in a wall.
- TAILLOIR.** (Fr.) The name which the French give to the *abacus*.
- TALON.** (Fr.) The name given by the French to the *ogee*.
- TAMBOUR.** (Fr. a drum.) A term denoting the naked ground on which the leaves of the Corinthian and Composite capitals are placed. It signifies also the wall of a circular temple surrounded with columns, and further the circular vertical part below a cupola as well as above it.
- TANGENT.** (Lat. *Tango*.) A line drawn perpendicular to the extremity of the diameter of a circle, and therefore touching it only at one point. In trigonometry it is a line drawn perpendicularly from the extremity of the diameter, at one end of the arc, and bounded by a straight line drawn from the centre through the other.
- TAPERING.** A term expressive of the gradual approach, as they rise, of the sides of a body to each other, so that if continued they would terminate in a point.
- TARRAS.** See Book II. Chap. II. Sect. 10. It is a strong cement, useful in aquatic works.
- TASSALS.** (Fr.) The pieces of timber lying under the mantel tree.
- TASTE.** See p. 673. 676.
- TATTI SANSOVINO.** See ARCHITECTS, list of, 229.

**TAVELLÆ.** (Lat.) Bricks in ancient Roman architecture which were seven inches long and three and a half broad.

**TAXIS.** (Gr.) A term used by Vitruvius to signify that disposition which assigns to every part of a building its just dimensions. Modern architects have called it *ordnance*.

**TAYLOR, SIR ROBERT.** See ARCHITECTS, list of, 302.

**TEAZE TENON.** A tenon on the top of a post, with a double shoulder and tenon from each, for supporting two level pieces of timber at right angles to each other.

**TECTORIUM OPUS.** (Lat.) A name in ancient architecture given to a species of plastering used on the walls of their apartments.

**TELAMONES.** (Gr. Τάλα, to support.) Figures of men used in the same manner as Caryatides. They are sometimes called *atlantes*.

**TEMONES.** (Gr. Τεμνος.) The places in a temple where statues were placed.

**TEMPERED.** An epithet applied to bricks which may be cut with ease, and reduced with ease to a required form. The term is also applied to mortar and other cement, which has been well beaten and mixed together.

**TEMPLA.** (Lat.) Timbers in the roof of the Roman temples, which rested on the *cantherii*, or principal rafters, similar to our purlins.

**TEMPLATE.** An improper orthography for **TEMPLET**, which see.

**TEMPLE.** (Lat.) Generally an edifice erected for the public exercise of religious worship. The subject of temples has been so fully considered in the body of the work, under the different heads of Ancient, Grecian, and Roman Architecture, that we shall here confine ourselves to the description of the different species of temples mentioned by Vitruvius. The difference between temples is by that author thus given (book iii.):—A temple is said to be *in antis* when it has antæ or pilasters in front of the walls, which enclose the cells, with two columns between the antæ. A plan of such a temple is seen in *fig. 1047*.

Fig. 1047.

Fig. 1048.

It was crowned with a pediment, and was not dissimilar to the prostylos temple, to which we shall presently come. In the figure, A is the cell, aa the antæ, and if in front of them, the columns bbbb were placed, it would be a *prostyle* temple; C is the door of the cell, and B the pronaos. The appearance in front of this species is the same as the *amphiprostyle* temple, which is given in *fig. 1048*., and wherein columns are also placed in front of the antæ. Of the *prostyle* temple, an example, that of the temple of Jupiter and Faunus, existed on the island of the Tyber at Rome. In the figure of the *amphiprostyle* temple, A is the cell, B the pronaos, C the posticus, D the door of the cell, and aa are the antæ. It will be immediately seen that the same elevation will apply (*fig. 1049*.) to both the plans just given. The *amphiprostyle* temple, be it observed, has columns in the rear as well as in front, and is distinguished by that from the *prostylos* of *fig. 1047*., wherein the columns bbbb (*fig. 1048*.) would make that *prostylos* which, but for them, would be merely a temple in *antis*. The *amphiprostylos* then only differs from the *prostyle* by having columns in the rear, repeated similarly to those in the front. The *fig. 1049*.

applies on double the scale of the plan to both *figs.* 1047. and 1048., and is a diastyle tetrastyle temple, that is, one whose intercolumniations (see COLONNADE) are of three diameters, and the number of whose columns is four.

Fig. 1019.

A *peripteral temple* had six columns in front and rear, and eleven on the flanks, counting the two columns on the angles (see *fig.* 1050.), and these were so placed that their

Fig. 1050.

distance from the wall was equal to an intercolumniation or space between the columns all round, and thus it formed a walk around the cell. In *fig.* 1051. is the elevation of

Fig. 1051.

the species, which is hexastyle and eustyle, that is, with six columns in front, whose intercolumniation is *eustyle*, or of two diameters and a quarter. (See COLONNADE.) In this figure, which is to a double scale of the plan, *aaa* are *acroteria*.

The *pseudo-dipteral temple* was constructed with eight columns in front and rear, and with fifteen on the sides, including those at the angles, see *fig.* 1052. The walls of the

Fig. 1052.

Fig. 1053.

cell are opposite to the four middle columns of the front and of the rear. Hence, from the walls to the front of the lower part of the columns, there will be an interval equal to two intercolumniations and the thickness of a column all round. No example existed of such a temple at Rome; but there was one to Diana, built by Hermogenes of Alabanda, in Magnesia, and that of Apollo by Menesthes. The dipteral temple (*fig.* 1053.) is octastylus like the former, and with a pronaos and posticum, but all round the cell are two ranks of columns: such was the temple of Diana, built by Ctesiphon. The

Fig. 1051.

elevation (*fig.* 1054.) is the same in the dipteral and pseudo-dipteral temple, and in the figure is with the systyle intercolumniation.

The *hypæthral temple*, or that uncovered in the centre, is decastylos in the pronaos and posticum; it is in other respects (see *fig.* 1055.) similar to the dipteral, except that

Fig. 1055.

in the inside it has two stories of columns all round, at some distance from the walls, after the manner of the peristylia of porticoes (see *fig. 1056.*), in which one half is the elevation and the other half the section of the temple.

Fig. 1056.

We have described the peripteral temple, but there is still another connected with that species, though distinct, and that is the pseudo-peripteral, or false peripteral, in which there is no passage round the walls of the cell, but an appearance of surrounding columns (see *fig. 1057.*).

Fig. 1057.

By this arrangement more room was given to the space of the cell.

Fig. 1058.

The elevation of this is given in *fig. 1058*. Vitruvius thus describes, as follows, the proportions of the Tuscan temple :

The length of the site of the temple intended (see *fig. 1059*.) must be divided into six parts, whence, by subtracting one part, the width thereof is obtained. The length is then divided into two parts, of which the furthest is assigned to the cell, that next the front to the reception of the columns.

The above width is to be divided into ten parts, of which three to the right and three to the left are for the smaller cells, or for the *alæ*, if such are required; the remaining four are to be given to the central part. The space before the cells in the pronaos is to have its columns so arranged that those at the angles are to correspond with the *antæ* of the external walls: the two central ones opposite the walls between the *antæ* and the middle of the temple are to be so disposed, that between the *antæ* and the above columns, and in that direction, others may be placed.

Their thickness below is to be one-seventh of their height, their height one-third of the width of the temple, and their thickness at top is to be one-fourth less than their thickness at bottom. Their bases are to be half a diameter in height. The plinths, which are to be circular, are half the height of the base, with a torus and fillet on them as high as the plinth.

The height of the capital is to be half a diameter, and the width of the abacus equal to the lower diameter of the column. The height of the capital must be divided into three parts, whereof one is assigned to the plinth or abacus, another to the echinus, the third to the hypotrachelium, with its apophyge.

Over the columns coupled beams are laid of such height as the magnitude of the work may require. Their width must be equal to that of the hypotrachelium at the top of the column, and they are to be so coupled together with dovetailed dowels as to leave a space of two inches between them. Above the beams and walls the *mutuli* project one-fourth of the height of the columns. In front of these members are fixed, and over them, the tympanum of the pediment, either of masonry or timber.

Of circular temples there are two species; the *monopteral* (*fig. 1060*.) having columns without a cell, and the *peripteral* with a cell as in *fig. 1061*. In this last the clear diameter of the cell within the walls is to be equal to the height of the columns above the pedestal. Of this species was the celebrated temple at Tivoli, in the admiration whereof no dissident from its allowed beauty has hitherto been recorded. With it situation has doubtless much to do.

Fig. 1059.

Fig. 1060.

Fig. 1061.

**TEMPLET.** A mould used in masonry and brickwork for the purpose of cutting or setting out the work. When particular accuracy is required, two templets should be used, one for moulding the end of the work, and its reverse for trying the face. When many stones or bricks are required to be wrought with the same mould, the templets ought to be made of copper.

The term is also used to denote a short piece of timber sometimes laid under a girder, particularly in brick buildings.

**TENON.** (Fr. Tenir.) A projecting rectangular prism formed on the end of a piece of timber to be inserted into a mortise of the same form.

**TENON SAW.** One with a brass or steel back for cutting tenons.

**TENSION.** The stretching or degree of stretching to which a piece of timber or other material is strained by drawing it in the direction of its length.

**TEOCOPOLI.** See **ARCHITECTS**, list of, 231.

**TEPIDARIUM.** (Lat.) A name given to one of the apartments of a Roman bath.

**TERM or TERMINUS.** A sort of trunk, pillar, or pedestal often in the form of the frustum of an inverted obelisk with the bust of a man, woman, or satyr on the top.

**TERRA COTTA.** (It.) Baked or burnt earth, frequently used at an early period for the architectural decoration of a building. In the time of Pausanias there were in many temples statues of the deities made of this material. Bassi rilievi of terra cotta were frequently employed to ornament the friezes of temples. In modern times it has also been much used for architectural decoration, being plastic at first, easily worked, solid, and not expensive.

**TERRACE.** An area raised before a building above the level of the ground to serve as a walk. The word is sometimes but improperly used to denote a balcony or gallery.

**TESSELATED PAVEMENT.** A rich pavement of Mosaic work made of small square marbles, bricks, tiles, or pebbles, called *tessellæ* or *tessera*.

**TESSERA.** (Gr.) A cube or die. This name was, for what reason we are at a loss to conceive, applied to a composition used some years ago for covering flat roofs, but now, from its failure, quite abandoned.

**TESTUDO.** (Lat.) A name given by the ancients to a light surbased vault with which they ceiled the grand halls in baths and mansions. Generally, any arched roof.

**TETRADORON.** (Gr.) A species of brick four palms in length.

**TETRAGON.** (Gr.) A figure which has four sides and as many angles.

- TETRASPASTOS.** (Gr. *Τετρα*, four, and *Σπασσω*, to draw). A machine working with four pulleys.
- TETRASTYLE.** (Gr. *Τετρα*, and *Στυλος*, a column.) See **COLONNADE**.
- THATCH.** The covering of straw or reeds used on the roofs of cottages, barns, and such buildings.
- THEATRE.** (Gr. *Θεατρον*, to see.) A place appropriated to the representation of dramatic spectacles. In respect of the ancient theatres see page 71.; and of modern theatres, Book III. Chap. III. Sect. 16.
- THEODOLITE.** An instrument used in surveying for taking angles in vertical or horizontal planes.
- THEODORUS.** See **ARCHITECTS**, list of, 1.
- THEOREM.** A proposition which is the subject of demonstration.
- THERMÆ.** See **BATH**.
- THOMAS OF CANTERBURY.** See **ARCHITECTS**, list of, 138.
- THOROUGH FRAMING.** The framing of doors and windows, a term almost obsolete.
- THOROUGH LIGHTED ROOMS.** Such as have windows on opposite sides.
- THRESHOLD OF A DOOR.** The sill of the door frame.
- THROAT.** See **GORGE** and **CHIMNEY**.
- THRUST.** The force exerted by any body or system of bodies against another. Thus the thrust of an arch is the power of the arch stones considered as a combination of wedges to overturn the abutments or walls from which the arch springs.
- THYNNE.** See **ARCHITECTS**, list of, 235.
- TIE.** (Sax. *Tian*, to bind.) A timber-string, chain, or iron rod connecting two bodies together, which have a tendency to diverge from each other, such as tie-beams, diagonal ties, truss-posts, &c. Braces may act either as ties or straining pieces. Straining pieces are preferable to ties, for these cannot be so well secured at the joints as straining pieces.
- TIE (ANGLE).** See **ANGLE BRACE**.
- TIE BEAM.** The beam which connects the bottom of a pair of principal rafters, and prevents them from thrusting out the wall.
- TIERCE POINT.** The vertex of an equilateral triangle. Arches or vaults of the third point, which are called by the Italians *di terzo acuto*, are such as consist of two arcs of a circle intersecting at the top.
- TIELANDUS.** See **ARCHITECTS**, list of, 72.
- TIGE.** (Fr.) A term used by the French, signifying the shaft of a column.
- TILE.** (Sax. *Tigel*.) A thin piece or plate of baked clay or other material used for the external covering of a roof. See Book II. Chap. III. Sect. 9. In ancient buildings two forms of tiles were used. The *imbrex*, placed in regular rows to receive the shower, and the *tegula*, which covered and prevented the rain from penetrating the joints. The latter were fixed at the eaves with upright ornamental pieces called *antefixæ*, which were also repeated along the ridge at the junction of the tiles. The present common tiles of Italy are on this principle, and are shown by *fig.* 1062.

Fig. 1062.

- TILE CREASING.** See **CREASING**.
- TILING.** See Book II. Chap. III. Sect. 2.
- TIMBER.** (Sax. *Timbrian*, to build.) Properly denotes all such wood, either growing or cut down, as is suited to the purposes of building. A single piece of wood, similarly employed, is so called as one of the *timbers* of a floor, roof, &c. See Book II. Chap. II. Sect. 4.
- TIODAS.** See **ARCHITECTS**, list of, 73.
- TOMB.** (Gr. *Τυμβος*.) A grave or place for the interment of a human body, including also any commemorative monument raised over such a place. The word embraces every variety of grave and sepulchral monument, from the meanest grave to the most sumptuous mausoleum.
- TONDINO.** (It.) Same as **TORUS**, which see.
- TONGUE.** See **GROOVE**.
- TOOLS.** (Sax.) Instruments used by artificers for the reduction of any material to its

- intended form. An account of those used by each set of workmen will be found under each department in Book II. Chap. III.
- TOOTH.** The iron or steel point in a gage which marks the stuff in its passage, or draws a line parallel to the arris of the piece of wood.
- TOOTHING.** A projecting piece of material which is to be received into an adjoining piece. A tongue or series of tongues.
- TOP BEAM.** The same as **COLLAR BEAM**, which see.
- TOP RAIL.** The uppermost rail of a piece of framing or wainscotting, as its name imports.
- TORSKL.** The same as **TASSAL**, which see.
- TORSION.** The twisting strain on any material.
- TORUS.** (Lat.) A large moulding whose section is semicircular, used in the bases of columns. The only difference between it and the astragal is in the size, the astragal being much smaller.
- TOWER.** (Sax.) A lofty building of several stories, round or polygonal.
- TOWN HALL.** A building in which the affairs of a town are transacted. See Book III. Chap. III. Sect. 7.
- TRABEATION.** Another term for **ENTABLATURE**.
- TRANS.** The Latin term for a wall-plate.
- TRACERY.** In Gothic architecture, the intersection, in various ways, of the mullions in the head of a window, the subdivisions of groined vaults, &c.
- TRAMMEL.** An instrument for describing an ellipsis by continued motion.
- TRANSEPT** (quasi, transeptum). The transverse portion of a cruciform church; that part which is placed between and extends beyond those divisions of the building containing the nave and choir. It is one of the arms projecting each way on the side of the stem of the cross.
- TRANSOM.** A beam across a window of two lights in height. If a window have no transom it is called a clear story window.
- TRANSTRA.** (Lat.) The horizontal timbers in the roofs of ancient Roman buildings.
- TRANSVERSE.** Lying in a cross direction. The *transverse strain* of a piece of timber is that sidewise, by which it is more easily bent or broken than when compressed or drawn as a tie in the direction of its length.
- TRAPEZIUM.** (Gr.) In geometry, a quadrilateral figure whose opposite sides are not parallel.
- TRAVERSE.** A gallery or loft of communication in a church or other large building.
- TREAD OF THE STEP OF A STAIR.** The horizontal part of it.
- TREFOIL.** In Gothic architecture, an ornament consisting of three cusps in a circle.
- TRELICE.** A reticulated framing made of thin bars of wood for screens; windows where air is required for the apartment, &c.
- TRESSEL or TRUSSEL.** Props for the support of any thing, the under surface of which is horizontal. Each trussel consists of three or four legs attached to a horizontal part. When the tressels are high the legs are sometimes braced. Tressels are much used in building for the support of scaffolding, and by carpenters and joiners for ripping and cross-cutting timber, and for many other purposes.
- TRIANGLE.** (Lat.) A plane rectilinear figure of three sides, and consequently of three angles. In measuring, all rectilinear figures must be reduced to triangles, and in constructions for carpentry all frames of more than three sides must be reduced to triangles to prevent a revolution round the angles.
- TRIANGULAR COMPASSES.** Such as have three legs or feet by which any triangle or any three points may be taken off at once.
- TRICLINIUM.** (Lat.) The room in the Roman house wherein the company was received, and seats placed for their accommodation. It was raised two steps from the peristyle, and had therein a large window, which looked upon the garden. The aspect of winter triclinia was to the west, and of summer triclinia to the east. See p. 102.
- TRIFORIUM.** (Lat.) The gallery or open space between the vaulting and the roof of the aisles of a church, generally lighted by windows in the external wall of the building, and opening to the nave, choir, or transept over the main arches. It occurs only in large churches, and is varied in the arrangement and decoration of its openings in each succeeding period of architecture.
- TRIGLYPH.** (Gr. *Τρεῖς*, and *Γλυφῆ*, a channel.) The vertical tablets in the Doric frieze chamfered on the two vertical edges, and having two channels in the middle, which are double channels to those at the angles. In the Grecian Doric, the triglyph is placed upon the angle; but, in the Roman, the triglyph nearest the angle is placed centrally over the column.
- TRIGONOMETRY.** (Gr. *Τρεῖς*, three, *Γωνία*, an angle, and *Μετρω*, I measure.) The science of determining the unknown parts of a triangle from certain parts that are given. It is either *plane* or *spherical*; the first relates to triangles composed of three right lines, and the

second to triangles formed upon the surface of a sphere by three circular arcs. This latter is of less importance to the architect than the former, which is, for his purpose, sufficiently explained in Book II. Chap. I. Sect. 14.

**TRILATERAL.** (Lat.) Having three sides.

**TRIM.** (Verb.) To fit to any thing; thus, to *trim up*, is to fit up.

**TRIMMED.** A piece of workmanship fitted between others previously executed, which is then said to be *trimmed in* between them. Thus, a partition wall is said to be trimmed up between the floor and the ceiling; a post between two beams; a trimmer between two joists.

**TRIMMED OUT.** A term applied to the trimmers of stairs when brought forward to receive the rough strings.

**TRIMMER.** A small beam, into which are framed the ends of several joists. The two joists, into which each end of the trimmer is framed, are called *trimming joists*. This arrangement takes place where a well-hole is to be left for stairs, or to avoid bringing joists near chimneys, &c.

**TRINE DIMENSIONS.** Those of a solid, including length, breadth, and thickness; the same as threefold dimensions.

**TRIPOD.** (Gr. *Tpeis*, and *Πους*, a foot.) A table or seat with three legs. In architectural ornament its forms are extremely varied, many of those of the ancients are remarkable for their elegance and beauty of form.

**TRISECTION.** The division of any thing into three equal parts.

**TROCHILUS.** (Gr. *Τροχίλος*, a pulley.) An annular moulding whose section is concave, like the edge of a pulley. It is more commonly called a *scotia*, and its place is between the two tori of the base of a column.

**TROCHOID.** (Gr. *Τροχος* a wheel, and *Εἶδος*, shape.) A figure described by rolling a circle upon a straight line, such circle having a pin or fixed point in its circumference upon a fixed plane, in or parallel to the plane of the moving circle. It is also called a cycloid.

**TROPHONIUS.** See ARCHITECTS, list of, 3.

**TROPHY.** (Gr. *Τροπαιον*.) An ornament representing the trunk of a tree charged with various spoils of war.

**TROUGH.** (Sax. *Troh*.) A vessel in the form of a rectangular prism, open on the top for holding water.

**TROUGH GUTTER.** A gutter in the form of a trough, placed below the dripping eaves of a house, in order to convey the water from the roof to the vertical trunk or pipe by which it is to be discharged. It is only used in common buildings and outhouses.

**TRUNCATED.** (Lat. *Trunco*, I cut short.) A term employed to signify that the upper portion of some solid, as a cone, pyramid, sphere, &c. has been cut off. The part which remains is called a *frustum*.

**TRUNK.** That part of a pilaster which is contained between the base and the capital; also a vessel open at each end for the discharge of water, rain, &c.

**TRUSS.** (Fr. *Trousse*.) A combination of timber framing, so arranged, that if suspended at two given points, and charged with one or more weights in certain others, no timber would press transversely upon another except by strains exerting equal and opposite forces. The principle of a truss is explained at p. 546.

**TRUSS PARTITION.** One containing a truss within it, generally consisting of a quad angular frame, two braces, and two queen posts, with a straining post between them, opposite to the top of the braces.

**TRUSSED BEAM.** One in which the combination of a truss is inserted between and let into the two pieces whereof it is composed.

**TRUSSING PIECES.** Those timbers in a roof that are in a state of compression.

**TRY.** (Verb.) To plane a piece of stuff by the rule and square only.

**TUBE.** (Lat.) A substance perforated longitudinally; generally quite through its length.

**TUMBLED IN.** The same as *trimmed in*. See TRIMMED.

**TUNNEL.** (Fr.) A subterranean channel for carrying a stream of water under a road, hill, &c.

**TURNING PIECE.** A board with a circular edge for turning a thin brick arch upon.

**TURPENTINE.** A resinous juice extracted from several trees belonging to the genus *Pinus*. All turpentine is obtained by exudation and hardening of the juice flowing from incisions into the pine trees. To obtain the oil of turpentine, the juice is distilled in an apparatus like the common still, and water is introduced with the turpentine.

**TURRET.** (Lat. *Turris*.) A small tower often crowning the angle of a wall, &c.

**TUSCAN ORDER.** See Book III. Chap. I. Sect. 3.

**TUSK.** A bevel shoulder made above a tenon, and let into a girder to give strength to the tenon.

**TYMPANUM.** (Gr.) The naked face of a pediment (see PEDIMENT) included between the

level and raking mouldings. The word also signifies the die of a pedestal, and the panel of a door.

**TYPE.** (Gr. *τύπος*.) A word expressing by general acceptance, and consequently applicable to, many of the varieties involved in the terms model, matrix, impression, &c. It is, in architecture, that primitive model, whatever it may have been, that has been the foundation of every style, and which has guided, or is supposed to have guided, the forms and details of each. What it was in each style is still only conjecture, and forms the ground for the various observations on them in various parts of the body of this work.

**TYPE.** The canopy over a pulpit.

## U.

**UNDERPINNING.** Bringing a wall up to the ground sill. The term is also used to denote the temporary support of a wall, whose lower part or foundations are defective, and the bringing up new solid work whereon it is in future to rest.

**UNGULA.** The portion of a cylinder or cone comprised by part of the curved surface, the segment of a circle, which is part of the base, and another plane.

**UNIVERSITY.** An assemblage of colleges under the supervision of a senate, &c. See Book III. Chap. III. Sect. 8.

**UPHERS.** Fir poles, from four to seven inches in diameter, and from twenty to forty feet in length. They are often hewn on the sides, but not entirely to reduce them square. They are chiefly used for scaffolding and ladders, and are also employed in slight and common roofs, for which they are split.

**UPRIGHT.** The elevation of a building; a term rarely used.

**URIA, DE.** See ARCHITECTS, list of, 209.

**URILLA.** See HELIX.

**URN.** (Lat.) A vase of a circular form, destined among the ancients to receive and preserve the ashes of the dead.

**USTAMBER.** See ARCHITECTS, list of, 80.

## V.

**VAGINA.** (Lat.) The lower part of a terminus in which the statue is apparently inserted.

**VALDEVIRA.** See ARCHITECTS, list of, 224.

**VALERIUS OF OSTIA.** See ARCHITECTS, list of, 32.

**VALLEY.** (Lat.) The internal meeting of the two inclined sides of a roof. The rafter which supports the valley is called the *valley rafter* or *valley piece*, and the board fixed upon it for the leaden gutter to rest upon is called the *valley board*. The old writers called the valley rafters *sleepers*.

**VALUATIONS OF PROPERTY.** See APPENDIX, p. 882.

**VALVED.** Any thing which opens on hinges.

**VANBRUGH.** See ARCHITECTS, list of, 270.

**VANE.** A plate of metal shaped like a banner fixed on the summit of a tower or steeple, to show the direction of the wind.

**VANISHING LINE.** In perspective, the intersection of the parallel of any original plane and the picture is called the vanishing line of such plane. The *vanishing point* is that to which all parallel lines in the same plane tend in the representation.

**VANVITELLI.** See ARCHITECTS, list of, 291.

**VARIATION OF CURVATURE.** The change in a curve by which it becomes quicker or flatter in its different parts. Thus, the curvature of the quarter of an ellipsis terminated by the two axes is continually quicker from the extremity of the greater axis to that of the lesser. There is no variation of curvature in the circle.

**VARNISH.** A glossy coat on painting or the surface of any matter. It consists of different resins in a state of solution, whereof the most common are mastic, sandarac, lac, benzoin, copal, amber, and asphaltum. The menstrua are either expressed, or essential oils, or alcohol.

**VASE.** (Lat. *Vas*.) A term applied to a vessel of various forms, and chiefly used as an ornament. It is also used to denote the bell, or naked form, to which the foliage and volutes of the Corinthian and Composite capitals are applied. The *vases of a theatre* in ancient architecture were bell-shaped vessels placed under the seats to produce reverberation of the sound.

**VAULT.** (It. *Volto*.) An arched roof over an apartment, concave towards the void, whose section may be that of any curve in the same direction. Thus a *cylindric vault* has its surface part of a cylinder. A *full-centred vault* is formed by a semi-cylinder. When a vault is greater in height than half its span, it is said to be *surmounted* when less *surbased*. A *rampant vault* springs from planes not parallel to the horizon. The *double vault* occurs in the case of one being above another. A *conic vault* is formed of part of the surface

- of a cone, as a *spherical vault* consists of part of the surface of a sphere. The plane of an *annular vault* is contained between two concentric circles. A vault is said to be *simple* when formed by the surface of some regular solid round one axis, and *compound* when formed of more than one surface of the same solid or of two different solids. A *cylindro-cylindric vault* is formed of the surfaces of two unequal cylinders: and a *groined vault* is a compound one rising to the same height in its surfaces as that of two equal cylinders, or a cylinder with a cylindroid. The *reins of a vault* are the sides or walls that sustain the arch. See the section on ARCHES, Book II. Chap. I. Sect. 9.
- VELARIUM. (Lat.) The great awning which by means of tackle was hoisted over the theatre and amphitheatre to protect the spectators from the rain or the sun's rays.
- VELLAR CUPOLA. A term used by Alberti to denote a dome or spherical surface terminated by four or more walls, frequently used over large staircases and salons, and other lofty apartments.
- VENER. A very thin leaf of wood of a superior quality for covering doors or articles of furniture which are made of an inferior wood.
- VENETIAN DOOR. A door having side lights on each side for lighting an entrance hall.
- VENETIAN WINDOW. One formed with three apertures separated by slender piers from each other, whereof the centre one is much larger than those on the sides.
- VENT. The flue or funnel of a chimney; also any conduit for carrying off that which is offensive.
- VENTIDUCT. A passage or pipe for the introduction of fresh air to an apartment.
- VENTILATION. The continual supply of fresh air to an apartment, a subject which latterly has been considered so necessary, though much neglected as the moderns seem to think by their ancestors, that a volume would not hold the schemes that have been latterly proposed for that purpose. Generally it is enough for the architect to provide means for letting off the hot air of an apartment or building by apertures at the upper part of the rooms, &c., to which the hot air will ascend without afflicting with the currents of fresh air that are to be introduced those that inhabit them.
- VERMICULATED. (Lat.) A term applied to rustic-work which is so wrought as to have the appearance of having been eaten into by worms.
- VERTEX. (Lat. the top.) A term generally applied to the termination of any thing finishing in a point, thus we say the vertex of a cone, &c.
- VERTICAL ANGLES. The opposite ones made by two straight lines cutting each other.
- VERTICAL PLANE. One whose surface is perpendicular to the horizon.
- VESTIBULE. (Lat. Vestibulum.) An apartment which serves as the medium of communication to another room or series of rooms. In the Roman houses it appears to have been the place before the entrance where the clients of the master of the house, or those wishing to pay their court to him, waited before introduction. It was not considered as forming a part of the house. The entrance from the vestibulum led immediately into the *atrium*, or into the *cavædium*.
- VESTRY. (Lat. Vestiarium.) An apartment in, or attached to, a church for the preservation of the sacred vestments and utensils.
- VICE. A term in old records applied to a spiral or winding staircase. In mechanics a machine serving to hold fast any thing worked upon, whether the purpose be filing, bending, riveting, &c.
- VILLA. A country-house for the residence of an opulent person. Among the Romans there were three descriptions of villa, each having its particular destination, namely. The *Villa urbana*, which was the residence of the proprietor, and contained all the conveniences of a mansion in the city. The *Villa rustica*, which contained not only all that was essential to rural economy, such as barns, stables, &c., but comprised lodging apartments for all those who ministered in the operations of the farming establishment. The *Villa fructuaria* was appropriated to the preservation of the different productions of the estate, and contained the granaries, magazines for the oil, cellars for the wine, &c. See Book III. Chap. III. Sect. 22.
- VINCI, DA. See ARCHITECTS, list of, 181.
- VINEY. A house for the cultivation of vines. See CONSERVATORY.
- VISORIUM. (Lat.) See AMPHITHEATRE.
- VISUAL POINT. In perspective a point in the horizontal line in which the visual rays unite.
- VISUAL RAY. A line of light supposed to come from a point of the object to the eye.
- VITONI. See ARCHITECTS, list of, 168.
- VITRIFICATION. The hardening of argillaceous stones by heat.
- VITRUVIUS POLLIO. See ARCHITECTS, list of, 40.
- VITRUVIUS CERDO. See ARCHITECTS, list of, 41.
- VIVO. (Ital.) The shaft of a column.
- VOLUTE. A spiral scroll which forms the principal feature of the Ionic and Composite capitals.

VOMITORIA. (Lat.) See AMPHITHEATRE.

VOUSOIR. (Fr.) A wedge-like stone or other matter forming one of the pieces of an arch.  
See ARCH.

## W.

WAGON-HEADED CEILING. The same as cylindric ceiling. See VAULT.

WAINSCOT. (Dutch, Wayschot.) A term usually applied to the wooden lining of walls in panels. The wood originally used for this purpose was a foreign oak (see p. 482.); hence the name of the material became attached to the work itself.

WALKELYN. See ARCHITECTS, list of, 84.

WALL. A body of materials for the enclosure of a building and the support of its various parts. See Book II. Chap. I. Sect. 10.

WALLS OF THE ANCIENTS. *Emplecton, Isodomum, Pseudo-isodomum*. See MASONRY.

WALLS, CASED. Those faced up anew round a building, in order to cover an inferior material, or old work gone to decay.

WALNUT. A forest tree useful for building purposes. See p. 484.

WALSINGHAM. See ARCHITECTS, list of, 142.

WARE. See ARCHITECTS, list of, 289.

WARREN. See ARCHITECTS, list of, 250.

WATER-CLOSET. See p. 583.

WATER SHOOT. See SQUARE SHOOT.

WATER TABLE. See TABLE, WATER.

WAYNEFLETE. See ARCHITECTS, list of, 165.

WEATHER-BOARDING. See BOARDING FOR OUTSIDE WORK.

WEATHER-TILING. The covering an upright wall with tiles.

WEDGE. (Dan. Wegge.) An instrument used for splitting wood or other substances; it is usually classed among the mechanical powers. See p. 392.

WEIGHT. (Sax. Wigt.) In mechanics, a quantity determined by the balance; a mass by which other bodies are examined. It denotes anything to be raised, sustained, or moved by a machine as distinguished from the power, or that by which the machine is put in motion.

WEIGHT, in commerce, denotes a body of given dimensions, used as a standard of comparison for all others. By an act of parliament passed in June 1824, all weights were to remain as they then were, that act only declaring that the imperial standard pound troy shall be the unit or only standard measure of weight from which all other weights shall be derived and computed; that this troy pound is equal to the weight of 22·815 cubic inches of distilled water weighed in air at the temperature of 62° of Fahrenheit's thermometer, the barometer being at 30 inches, and that there being 5760 grains in a troy pound, there will be 7000 such grains in a pound avoirdupois.

## TROY WEIGHT.

24 grains = 1 pennyweight.

480 . . . = 20 . . . . . = 1 ounce.

5760 . . . = 240 . . . . . = 12 . . . = 1 pound.

## AVOIRDUPOIS WEIGHT.

16 drams = 1 ounce.

256 . . . = 16 . . . = 1 pound.

7168 . . . = 448 . . . = 28 . . . = 1 quarter.

28672 . . . = 1792 . . . = 112 . . . = 4 . . . = 1 cwt.

573440 . . . = 35840 . . . = 2240 . . . = 80 . . . = 20 . . . = 1 ton.

The avoirdupois pound : pound troy :: 175 : 144, or :: 11 : 9 nearly; and an avoirdupois pound is equal to 1 lb. 2 oz. 11 dwts. 16 grains troy. A troy ounce = 1 oz. 1·55 dr. avoirdupois.

The following is a table of weights according to the new French system.

Names.	French value.	English value.
Millier,	1000 kilogrammes = 1 French ton	= 19·7 cwt.
Quintal,	100 kilogrammes	= 1·97 cwt.
Kilogramme,	{ Weight of one cubic decimeter of water of the temperature of 39° 12' Fahrenheit.	= { 2·6803 lbs. troy. 2·5055 lbs. avoirdupois.
Hectogramme,	$\frac{1}{100}$ th of kilogramme	= { 3·2 ounces troy. 3·52 ounces avoirdupois.
Decagramme,	$\frac{1}{1000}$ th of kilogramme	= { 6·43 dwts. troy. 15·438 grains troy.
Gramme,	$\frac{1}{10000}$ th of kilogramme	= { 0·643 pennyweight. 0·032 ounce troy.
Decigramme,	$\frac{1}{100000}$ th of kilogramme	= 1·5438 grain troy.

The following table exhibits the proportion of weights in the principal places of Europe to 100 lbs. English avoirdupois.

100 lbs. English	=	91 lbs. 8 oz.	for the pound of	Amsterdam, Paris (old), &c.	
—	=	96	8	—	Antwerp or Brabant.
—	=	88	0	—	Rouen (the Viscounty weight).
—	=	106	0	—	Lyons (the city weight).
—	=	90	9	—	Rochelle.
—	=	107	11	—	Toulouse and Upper Languedoc.
—	=	113	0	—	Marseilles or Provence.
—	=	81	7	—	Geneva.
—	=	93	5	—	Hamburgh.
—	=	89	7	—	Frankfort, &c.
—	=	96	1	—	Leipsic, &c.
—	=	137	4	—	Genoa.
—	=	132	1	—	Leghorn.
—	=	153	11	—	Milan.
—	=	152	0	—	Venice.
—	=	154	10	—	Naples.
—	=	97	0	—	Seville, Cadiz, &c.
—	=	104	13	—	Portugal.
—	=	96	5	—	Liege.
—	=	112	0 $\frac{3}{4}$	—	Russia.
—	=	107	0 $\frac{1}{4}$	—	Sweden.
—	=	89	0 $\frac{1}{2}$	—	Denmark.

The Paris pound (poids de marc of Charlemagne) contained 9216 Paris grains; it was divided into 16 ounces, each ounce into 8 gros, and each gros into 72 grains. It is equal to 7561 English troy grains.

The English troy pound of 12 ounces contains 5760 troy grains = 7021 Paris grains. The English avoirdupois pound of 16 ounces contains 7000 English troy grains, and is equal to 8538 Paris grains.

To reduce Paris grains to English troy grains, divide by	}	1·2189.
Or, to reduce English troy grains to Paris grains, multiply by		
To reduce Paris ounces to English troy, divide by	}	1·015734.
To reduce English troy ounces to Paris, multiply by		

**WEIGHTS OF A SASH** are two weights by which the sash is suspended and kept in the situation to which it is raised by means of cords passing over pulleys. The vertical sides of the sash frames are generally made hollow in order to receive the weights, which, by this means are entirely concealed. Thus, to keep the sash in suspension, each weight must be half the weight of the sash. The cords should be of good quality, or they soon fret to pieces.

**WELCH GROINS.** A groin formed by the intersection of two cylindrical vaults, one whereof is of less height than the other.

**WELL.** A deep circular pit, or sort of shaft, sunk by digging down through the different strata or beds of earthy or other materials of the soil, so as to form an excavation for the purpose of containing the water of some spring or internal reservoir, by which it may be supplied.

**WELL-HOLE.** In a flight of stairs, the space left in the middle beyond the ends of the steps.

**WESTON.** See ARCHITECTS, list of, 137.

**WHEEL.** (Sax.) In mechanics, an engine consisting of a circular body turning on an axis, for enabling a given power to move or overcome a given weight or resistance. This machine may be referred to the lever.

**WHEEL WINDOW.** In Gothic architecture, a circular window, with radiating mullions, resembling the disposition of the spokes of a wheel.

**WHESTONE.** A stone of fine quality by which tools for cutting wood are brought to a fine edge, after being ground upon a gritstone, or grinding-stone, to a rough edge.

**WHITE LEAD.** A material forming the basis of most colours in house-painting. The common method of making it is by rolling up thin leaden plates spirally, so as to leave the space of about an inch between each coil. These are placed vertically in earthen pots, at the bottom of which is some good vinegar. The pots are covered, and exposed for a length of time to a gentle heat in a sandbath, or by bedding them in dung. The vapour of the vinegar, assisted by the tendency of lead to combine with the oxygen which is present, corrodes the lead, and converts the external portion into a white substance which comes off in flakes. These are washed and dried in stoves in lumps, and form the white lead of the painters.

**WICKET.** A small door made in a gate.

**WILLIAM OF SENS.** See ARCHITECTS, list of, 100.

**WILLIAM OF WYKEHAM.** See ARCHITECTS, list of, 141

**WIND-BEAM.** An obsolete name for a COLLAR-BEAM.

**WINDLASS or WINDLACE.** A machine for raising weights, in which a rope or chain is wound about a cylindrical body moved by levers; also a handle by which anything is turned.

**WINDOW.** An aperture in a wall for the transmission of light to an apartment. See Book III. Chap. I. Sect. 20.

**WINE CELLAR.** The apartment on the basement story, under ground, for stowing wine. The most important point in its construction is its being kept at a cool equal temperature. See BINNS.

**WIRE.** A small flexible bar of metal, elongated by means of a machine called a draw-bench.

**WITH.** (Sax.) The partition between two chimney flues. See CHIMNEY.

**WOOD.** (Sax.) A fibrous material much used in building, and formed into shape by edge tools. The different sorts in use form the subject of Sect. 4. Chap. II. Book II.

**WOOD BRICKS.** Blocks of wood cut to the form and size of bricks, inserted in the interior walls as holds for the joinery.

**WORKING DRAWINGS.** See Book II. Chap. IV. Sect. 4.

**WOTTON, SIR HENRY.** See ARCHITECTS, list of, 251.

**WREATHED COLUMNS.** Those which are twisted in the form of a screw, also very appropriately called contorted columns.

**WREN.** See ARCHITECTS, list of, 264.

## X.

**XENODOCHIUM.** (Gr. *Ξενος*, a guest, and *Δεχομαι*, to receive.) A name given by the ancients to a building for the reception of strangers.

**XYSTUS.** (Gr.) In ancient architecture, a spacious portico, wherein the *athletæ* exercised themselves during winter. The Romans called, on the contrary, their *hypæthral* walks *xysti*, which walks were by the Greeks called *περιδρομίδες*.

## Y.

**YARD.** A well known measure of three feet.

## Z.

**ZAX.** An instrument used for cutting slates.

**ZIGZAG MOULDING.** An ornament used in Gothic architecture. See p.174.

**ZINC.** A metal now much used in building. See Book II. Chap. II. Sect. 7.

**Zocco and Zoccolo.** (It.) The same as **SOCLE**, which see.

**ZOPHORUS.** The same as **FRIEZE**, which see.

**ZOTHECA.** A small room or alcove, which might be added to, or separated from, the room to which it adjoined.

## ADDENDA TO THE GLOSSARY.

---

**AUMBRYE.** A recess for holding the sacred vessels, &c., used in the mass.

**BARTISAN.** A turret on the summit of a tower, castle, or house, whereon was generally hoisted the standard or flag proper to the place.

**BEACON TURRET.** The turret of an angle of a tower, sometimes in border counties used for containing the apparatus for kindling at the shortest possible notice the *need-fire*.

**BED-MOULDINGS.** The mouldings under the corona in a cornice.

**BENATURA.** The holy water vessel placed at the entrance of churches, generally on the right hand of the outer or inner porch door, or both.

**CASSINOID.** An elliptic curve wherein the product of any two lines, drawn from the foci to a point in the curve, shall be equal to the rectangle under the semi-transverse and semi-conjugate diameters.

**CHEVET.** (Fr.) A term used by the French architects and antiquaries to denote the surrounding aisles of the choir of a cathedral, from their resemblance on the plan to the form of a bolster.

**CHRISMATORY.** A recess resembling a piscina, near the spot where the font originally stood, to contain the chrism, or holy oil, with which, after baptism, infants were anointed.

**COLUMEN.** The ridge piece of a roof. See *figs.* 91 and 92.

**CREDENCE.** The slab whereon, in the sacrifice of the mass, the elements are deposited previous to the oblation. Sometimes a plain recess, sometimes a slab on a bracket, but in all cases on the south side of the altar. The word is derived from *Credenza* (It.), a butlery or pantry.

**DOSSEL.** See *REREDOS*.

**EASTER OR HOLY SEPULCHRE.** A recess for the reception of the holy elements consecrated on the *Cœna Domini* or Maunday Thursday, till high mass on Easter-day. It is generally shallow, under an arch of obtuse or broad oggee form, rising about 3 feet from the ground, and should be on the north side of the church.

**EOPYLA.** A church with an apsis at the eastern end.

**EOTHOLA.** A church with an apsis at the western end.

**FALDSTOOL.** A moveable reading desk provided with a kneeling shelf at the foot thereof.

**FLAMBOYANT.** (F. Flaming or Flamelike.) A term applied in France to a style in Gothic architecture, in which the mullions and tracery terminate in waved lines of contrary flexure in flamelike forms. Examples of it occur about the beginning of the fifteenth century, and continue down to the middle of the sixteenth, being coincident nearly with the latter part of the period of our ornamented English, and the whole period of the florid English or Tudor style.

**GARGOUILLE.** See *GURGOYLE*.

**GURGOYLES.** The carved representations of men, monsters, &c., on the exterior of a church, and especially at the angles of the tower, serving as waterspouts, being connected with the gutters for the discharge of the water from the roof.

**HAGIOSCOPE.** (Gr. *ἅγιος*, holy, and *σκοπος*, mark.) An aperture made in the interior walls or partitions of a church, generally on the sides of the chancel arch, to enable persons in the aisles to see the elevation of the host. They are technically called *squints*, and sometimes *elevation apertures*.

**JURÉ.** The stand (often ending upwards in an eagle with expanded wings) in the choir of a church on which the Gospel is placed to be read, receiving its name from the words

"Jube Domine benedicere," used by the deacon when the missal is presented to him by the officiating priest at mass, previous to the reading of the Gospel.

**LEVELLING.** In the practice of levelling, it is evident that the level line carried on by means of a spirit level or other instrument used for the purpose, is a tangent to the earth: it is therefore necessary to make an allowance for the difference between the true level  $BC$  and the apparent level  $BD$ . This difference is, of course, equal to the excess  $DC$  of the secant of the arch of distance above the radius of the earth. Hence, from station to station, accordingly, allowance must be made. The subjoined table exhibits the corrections or values of  $C D$ .

Distance or BC.	Diff. of Lev. or CD.	Distance or BC.	Diff. of Lev. or CD.	
Yards.	Inches.	Miles.	Feet.	In.
100	0·026	$\frac{1}{4}$	0	$0\frac{1}{2}$
200	0·123	$\frac{1}{2}$	0	2
300	0·231	$\frac{3}{4}$	0	$4\frac{1}{2}$
400	0·411	1	0	8
500	0·643	2	2	8
600	0·925	3	6	0
700	1·260	4	10	7
800	1·645	5	16	7
900	2·081	6	23	11
1000	2·570	7	32	6
1100	3·110	8	42	6
1200	3·701	9	53	9
1300	4·344	10	66	4
1400	5·038	11	80	3
1500	5·784	12	95	7
1600	6·580	13	112	2
1700	7·425	14	130	1

**LOGGIA.** (It.) In its strict meaning a lodge; but usually signifying an open gallery.

**LOUVRE.** A turret or lantern over a hall or other apartment with openings for the escape of smoke or steam. The word is also used to denote the internally open polygonal tower over the intersection of the nave with the transepts of a church, as at Ely Cathedral, &c.

**LYCH-GATE or CORPSE GATE** (from the Anglo-Saxon *Leich*, a dead body). A gate at the entrance of a church-yard, where the coffin was set down for a few minutes before burial. It is generally wood, and thatched. Lych-gates are not of frequent occurrence in England. Wales has many.

**MISERERE.** A small moveable seat attached on an horizontal axis to a stall in a church or cathedral. It was so contrived that if, during the performance of religious ceremonies, the occupier of it slept, he would fall on (perchance) the floor. Hence the name.

**ORIENTATION.** (Lat. Oriens.) The deviation of a church from due east, it being supposed that the chancel points to that part of the east in which the sun rises on the day of the patron saint. This is, however, doubtful.

**PARCLOSE.** The screen which separates chapels (especially at the east end of the aisles) from the body of the church. They are usually of wood, but are also sometimes of stone.

**PARVIS TURRET.** The small tower which encloses the staircase to the parvis.

**PEW.** (Fr. Pieu.) An enclosed seat in a church. Pews were not used until long after the Reformation.

**POPPY HEADS, or POPPIES.** The terminations of the ends of open seats, often carved as heads, foliage, &c.

**PROTHESIS, TABLE OF.** See **CREDENCE.**

**RAYONNANT.** (Fr. Radiating.) A term applied in France to a style in Gothic architecture, wherein the mullions and tracery terminate in forms founded on the divergence of rays from certain centres. It prevailed from the latter end of the thirteenth until near the end of the fourteenth century.

**RESPONDS.** Half-piers at the east or west end of the nave, transepts, or choir. They are sometimes in the forms of brackets.

**SANCTE-BELL COT.** A small erection at the east end of the nave for the reception of the bell that gives notice of the *Sanctus* being commenced, and also to warn the people of the approaching elevation of the Host.

**SCREEDS.** See 2242.

**SEDLIA.** (Lat.) Seats provided for the clergy in the sacrifice of the mass, during that part of the office in which the "GLORIA" and "CREDO" are sung. Their proper place is only on the south side of the altar.

**SEPULCHRE.** See EASTER OR HOLY SEPULCHRE.

**SESQUIALTERAL.** In the proportion of one and a half.

**SPAWLED.** A term in masonry.

**SPIRE.** A spire which is octagonal, the sides facing the cardinal points being continued to the eaves which project over the tower, and the diagonal faces being intercepted at the bottom by semipyramidical projections whose edges are carried from the angles of the tower upwards, terminating in points on the corresponding oblique faces of the spire, is called a *broach spire*. (Fr. *Broche*, a spit.)

**SQUINT.** See HAGIOSCOPE.

**STOOL.** In brick-making the name given to the bench whereon the brick-moulder moulds the bricks.

**SYMBOLS.** Attributes or signs accompanying a statue or picture of a figure, in allusion to some passage in the life of the person represented, and hence often used as a figurative representation of the person himself. See p. 845.

**TIP.** (Verb.) To discharge a barrow or waggon load of any thing by turning it over.

**TRAPEZOID.** A quadrilateral figure having one pair of opposite sides parallel.

**TRIBUNE.** See APSIS.

**WASHER.** A flat piece of iron, or other metal, pierced with a hole for the passage of a screw, between whose nut and the timber it is placed to prevent compression on a small surface of the timber. Also the perforated metal plate of a sink or drain, which can be removed for letting off the waste water, and thus more easily cleansing it.

# INDEX.

\* \* The figures refer to the several paragraphs, except where the letter p. occurs, when they refer to the page.

## A.

ABATTOIRS, 2932, *et seq.* Ought to be established in large towns, 2932. Erected first at Paris, 2933, 2934. Those of Menilmontant and Montmartre, 2934. That of Menilmontant described, 2935, 2936.  
 Abbreviation, method of, in architectural composition, 2857.  
 Aberdeen, Lord, his opinion on the pointed arch, 300.  
 Aberystwith Castle, 402.  
 Abury, circles of stones, 16, 17. 40.  
 Adam, architect, *temp.* George III., 518.  
 Adam, Robert, an architect, *temp.* George III., 517. His work, *ib.*  
 Adams, Bernard, an architect, *temp.* Elizabeth, 442.  
 Adams, Robert, an architect, *temp.* Elizabeth, 440.  
 Adelpi, in the Strand, by Adam, 517.  
 Adi, temple of, at Ellora, 26.  
 Admiralty, designed by Ripley, 507.  
 Admiralty, in London, 2886. In Paris, 2887.  
 Adrian I., Pope, arts under, 281.  
 Adze, a carpenter's tool, 2003.  
 Æsthetics, in architecture, 2493.  
 Ayopai, or Fora, of the Greeks, 173.  
 Agricoles, architecture under, in Britain, 381.  
 Agrigentum, temples of Peace and Concord, 148.  
 Air drains, what, and use of, 1886.  
 Air vessel in pumps, 2223.  
 Aix-la-Chapelle, cathedral and palace of, 283.  
 Alæ of a Roman house, 249. 253.  
 Alatrium, Cyclopean remains at, 32.  
 Alberti, Leo Bat., 324. Account of his book, *De Re Edificatoria*, 325. His works, *ib.*  
 Alcalá, church and college of the Jesuits at, 371.  
 Alcalá, college and church of, 367. Palace of, 368.  
 Alcantara in Spain, bridge at, 193.  
 Alcázars of Segovia and Seville, 128.  
 Aleinous, house of, illustrative of Greek architecture, 138. Described, generally, *ib.*  
 Aldrich, dean of Christchurch, his works and skill as an architect, 490.

Alfred, king, his care of buildings of his time, 386.  
 Alhambra, ornamental detail of, 125. When founded, 127. Description of, 127.  
 All Saints', York, parochial church of, 421.  
 All Souls' College, Oxford, some part by Hawksmoor, 499.  
 Amberley Castle, built by Rede, bishop of Chichester, 413.  
 Amboise, palace at, Appendix, pp. 849, 850.  
 Ambresbury House, Wilts, by Webb, on Jones's designs, 465.  
 Amiens, cathedral at, 310. 314, 315. Comparison of, with Salisbury Cathedral, 315.  
 Ammanati, Bartol., his works, 331. His work *La Città*, *ib.*  
 Amphitheatre at Capua, 193.  
 Amphitheatres described. Those of Alba, at Otricoli, on the banks of the Garigliano, Puzzuoli, Capua, Verona, Pola, Arles, Saintes, Autun, Nismes, and Nice, 228. Coliseum described, with plan, section, and elevation, 192. 228, 229. First used by the Etruscans, 232. That at Nismes, dimensions of, 233.  
 Amphill, Beds., 423. 426.  
 Amphill, drawings relating to, 440.  
 Amsterdam, town hall at, 2897. Exchange at, 2939.  
 Anastasius II., architecture under, 271.  
 Angle of vision, in perspective, how to select, 2444, *et seq.*  
 Angle ribs for square domes, 2064.  
 Angle tie, what, 2009.  
 Anglo-Saxon architecture, 383, *et seq.* Characteristics of, 390. Buildings enumerated, 389. Columns, 390. Arches, *ib.* Capitals, *ib.* Windows, *ib.* Walls, *ib.* Ceilings and roofs, *ib.* Ornaments, *ib.* and 397. Plans, *ib.* Towers, *ib.* Style, three æras of, 391.  
 Annex, of Friburg, an early German architect, 365.  
 Annuities. See Compound Interest.  
 Annuities on lives, tables relating to, Appendix, p. 879, *et seq.*  
 Annulet, 2532.  
 Annunziata, choir of church of, at Florence, 325.  
 Anson, Lord, house for, in St. James's Square, by Stuart, 516.  
 Antæ, 2671.  
 Antefixæ; in a Roman house, 247.  
 Antoine, architect of the Mint at Paris, 360.

- Antonine column, 2603.  
 Antoninus and Faustina, Corinthian temple of, at Rome, 211.  
 Antwerp, town hall at, 2897.  
 Apodyterium of the Roman baths, 235.  
 Apollo Didymæus, Ionic temple of, near Miletus, 153.  
 Apollo Epicurius, temple of, in Arcadia, 150.  
 Apothea of a Roman house, 253.  
 Apron-piece in stairs, 2026.  
 Apsis, different forms of, Appendix, pp. 823, 824.  
 Aqueducts, earliest, of Rome, 223. That of Appius Claudius and Aqua Appia, *ib.* That of Quintus Martius, Aqua Julia, Aqua Tepula, Virginia, Aqua Claudia, *ib.* Cubic feet of water supplied to Rome, *ib.* That at Metz, *ib.* Castella in, 225. Venter in, *ib.* Injured, 238. Of the Greeks, 174.  
 Arabian architecture, its appearance after the seventh century, 118. Decline of, 128. Domestic architecture exemplified in a house at Algiers, 130.  
 Araeostyle Intercolumniation, 2605. 2608, 2609, 2613.  
 Aranjuez, royal pleasure house of, at, 371.  
 Arc, complement of, 1037. Supplement of, 1038. Sine of, 1039. Versed sine of, 1040. Tangent of, 1041. Cosine of, 1042. Cotangent of, 1043. Cosecant of, 1044.  
 Arc doubleau, Appendix, p. 835.  
 Arcades and arches, 2617, *et seq.*  
 Arcades. Theory of equality between weights and supports, 2618, 2619. 2626. Tuscan, 2621, 2622. Doric, *ib.* 2623. Ionic, *ib.* 2624. Corinthian, *ib.* 2625. Generally in respect of the theory, 2622. Chambers' law for regulating, 2626. Ratios between the solid and void parts, 2627. Tuscan, with pedestals, 2628. Doric, with pedestals, 2629. Ionic, with pedestals, 2630. Corinthian, with pedestals, 2631. Imposts and archivolts of, 2632. Vignola's rules in, 2633. Palladio's rules in, 2634. Columns used in, 2635. Scamozzi's rules in, *ib.* Their internal decorations, *ib.* At Massimi palace, *ib.* Late Mews at Charing Cross, *ib.* By Serlio, 2636. At Caprarola, 2637. At the Belvidere garden, Rome, 2638. By Palladio, 2639. By Vignola, for Borghese family, at Mondragone, 2640. At Basilica, Vicenza, 2641.  
 Arcades above Arcades, 2653, *et seq.* Best mode of disposing, according to Chambers, 2654, *et seq.* According to Scamozzi, 2655. In the Carità at Venice, *ib.* and 2656. In Palazzo Thiene, *ib.* Balustrades of, 2657. Doric above Tuscan, 2658, 2659. Ionic above Doric, 2660, 2661. Corinthian above Ionic, 2662. Of the Basilica at Vicenza, 2663. Confined by the ancients to theatres and amphitheatres, 2664.  
 Arcadius, architecture under, 271.  
 Arch, elliptical, to draw and find the joints, 1934—1937. Flat, in masonry, to draw the joints, without the centre, 1932. Flat, to draw and find the joints, 1932.  
 Arch, introduction of, effected great change in the art, 266.  
 Arch, no trace of, in the ruins of Babylon, 45. In Egypt, at Saccara, 75.  
 Arch of Claudius Drusus, niches at, 2776.  
 Arch of Constantine, 262. 2547.  
 Arch of the Goldsmiths at Rome, 195.  
 Arch of Janus, niches at, 2775.  
 Arch of Severus at Rome, 264.  
 Arch of Titus, 2547. Of Septimus Severus, *ib.*  
 Arch of Titus at Rome, 264.  
 Arch rampant, pointed, to draw and find the joints, 1943.  
 Arch unknown in Grecian architecture, 134.  
 Archer, pupil of Vanbrugh, 498.  
 Arches, Arabian, species most employed, 129. At Bussorah, 131.  
 Arches, equilibrium of, history, 1353—1363. Observations on friction, and methods of estimating, 1364—1389. Observations on the way in which arch stones support each other, 1390—1397. Geometrical application of foregoing, 1398, 1399. Experiments on surmounted arches, 1400. Application of the principles to the pointed arch, 1401. The same to a surmounted catenarian arch, 1402—1406. Application of the principles to surbated arches, 1407. Thrusts of arches: casinoid, cycloid, and ellipsis, 1408—1412. Raking arches, 1413—1416. Arch with a level extrados, 1417—1421. Different application of principles in the last case, 1422, 1431. Arches whose voussoirs increase towards the springing, 1432—1441. Mode in which an arch fails, 1442. Compound vaulting, 1443. Groined vaulting, 1444—1458. Application of principles of groined vaulting, 1459—1463. Model of a coved vault, principles applied to, 1464—1477. Spherical vaulting, principles applied to, 1478—1493. Adhesive power of mortar and plaster upon stones and bricks, 1494—1499.  
 Arches, inverted, in foundations, 1885.  
 Arches, to make working drawings for, and describe moulds of voussoirs, 1959—1966. Elliptical, cutting through a wall obliquely to bevells and moulds of, 1967—1970. In sloping walls, to make working drawings for, 1971, 1972. An abridged method of doing the last, 1973, 1974. Oblique, whereof the front slopes and rear are perpendicular to the axis, 1976—1979. Semicircular-headed, in a mass of masonry battering on an oblique plane, 1980—1983. On the quoins of a sloping wall to find the moulds, 1984—1987. In round towers or circular walls, 1988—1990. Oblique in a round

- sloping tower, intersecting a semicircular arch within it, 1991—1994.
- Architects of France, attached to Venetian in preference to Roman school, 358.
- Architectural design, maxims in, 2502.
- Bounding lines of buildings not sources of beauty, considered geometrically, 2503.
- Architecture, as a fine art, dependent on expression, 2492. Its end, *ib.* Genius in, what, *ib.* Taste in, what, *ib.* Æsthetics in, 2493. Considered in respect of rules of art, 2494. Fitness is the basis of proportion, 2496—2499. Fitness dependent on equilibrium, 2500. Stability, source of fitness in, *ib.* Maxims relating to fitness, 2502. Bounding lines of buildings, 2503. Interiors of buildings, beauty of, 2504. Types in, 2507. Styles in, all dependent on fitness, 2508. Unity and harmony in, 2509. Symmetry in, *ib.* Colour in, 2511. Polychromatic, 2512. Decoration of, 2513—2522.
- Architecture in 11th century not a liberal art, Appendix, p. 821.
- Architecture in 12th century, Appendix, p. 819.
- Architecture, secular, of France, Appendix, p. 847.
- Architecture of England from James I. to Anne, 451, *et seq.* Its character, 451. Deficient in picturesque beauty, 451.
- Architecture of England said by Walpole to have resumed her rights under George II., 506.
- Architecture of England under George I., 499, *et seq.* Under George II., 506, *et seq.* Under George III., 514, *et seq.*
- Architecture of the Greeks in its decline, 177.
- Architecture of Mexico, 109, *et seq.*
- Architecture not a fine art until founded on rules of proportion, 1.
- Architecture not confined to a single type, 1.
- Architecture, pointed. See "Pointed Architecture," and "Gothic Architecture."
- Architrave, to form, in joinery, 2196.
- Archivolts of arcades, 2632.
- Area given, method of enclosing in any regular polygon, 1518—1524.
- Arena of an amphitheatre, 228, 230, 231.
- Arena of the Roman Circus, 240.
- Argentino theatre at Rome, 2958.
- Argos, gate and chief tower of, Cyclopean, 29.
- Arithmetic and Algebra, introduction, 522, 523. Signs + and -, 524—526. Multiplication of simple quantities, 527—531. Whole numbers in respect to their factors, 532, 533. Division of simple quantities, 534—539. The properties of integers as respects their divisors, 540—548. Fractions, 549—554. Properties of fractions, 555—557. Addition and subtraction of fractions, 558—560. Multiplication and division of fractions, 561—574. Square numbers, 575—582. Square roots and the irrational numbers that result from them, 583—592. Impossible or imaginary quantities, 593—600. Cube roots, and the irrational numbers that result from them, 601—605. Of powers in general, 606—610. Calculation of powers, 611—616. Roots relatively to powers in general, 617—620. The representation of powers by fractional exponents, 620—625. Methods of calculation, and their mutual connection, 626—631. Logarithms, 632—638. Logarithmic tables now used, 639, 640. Method of expressing logarithms, 641—654. The subtraction of compound quantities, 655—658. The multiplication of compound quantities, 659—661. The division of compound quantities, 662—666. The resolution of fractions into infinite series, 667—679. The squares of compound quantities, 680—687. Extraction of roots of compound quantities, 688—692. Calculation of irrational quantities, 693—698. Of cubes, and the extraction of their roots, 699—701. The higher powers of compound quantities, 702—706. On the transposition of letters whereon the last rule rests, 707—711. The expression of irrational powers by infinite series, 712—718. Resolution of negative powers, 719—726. Arithmetical ratio, 727—731. Arithmetical proportion, 732—734. Arithmetical progression, 735—742. Summation of arithmetical progressions, 743—748. Geometrical ratio, 749—751. Greatest common divisor, 752, 753. Geometrical proportion, 754—762. Compound relations, 763—773. Geometrical progression, 774—782. Infinite decimal fractions, 783—796. Calculation of interest, 797—810. Solution of problems, 811—815. Resolution of simple equations, or of the first degree, 816—824. Resolution of two or more equations of the first degree, 825—832. Resolution of pure quadratic equations, 833—841. Resolution of mixed equations of the second degree, 842—848. Resolution of complete equations of the third degree, 849—860. Decimals, 861—867. Duodecimals, 868—872. Table of squares, cubes, and roots of numbers up to 1000.
- Arithmetical progression, 735—742. Summation of, 743—748.
- Arithmetical proportion, 732—734.
- Arithmetical ratio, 727—731.
- Armarium of a Roman house, 253.
- Arriaga, Luigi, a Spanish architect, 368.
- Arris of a piece of stuff, 2125.
- Arroyo Giuseppe, an architect of Spain, 368.
- Arts in England have never thoroughly taken root, 437. Flourished while in the hands of the clergy, *ib.*
- Arundel Castle, 394, 398.
- Asgill, Sir Charles, villa for, at Richmond, by Taylor, 515.

Ahlar stone walls, 1918. Facing, 1919—1924.  
 Asinelli tower, at Bologna, 2500.  
 Asphalte, 1876—1880.  
 Assisi, church of S. Francesco at, 318.  
 Assumption, church of, at Moscow, described, 375.  
 Astragal, Bead, or Baguette, 2532.  
 Athenians, their early superiority in the arts, 136.  
 Athens, early buildings at, of earth and clay, 136.  
 Atkinson's cement, 1863, 1864.  
 Atlantes, 2682.  
 Atreus, treasury of, at Mycene, description of, 35.  
 Atrium of a Roman house, 246. Different species of, &c., 247. In a house at Pompeii, 253.  
 Atrium, why so called in Roman houses, 181.  
 Attelborough, parochial church of, 408, 421.  
 Attics and basements, 2665, *et seq.* Examples of, 2668.  
 Attributes, in decoration, 2519, 2520.  
 Audley End, designs by Thorpe, 440.  
 Audley Inn, in Essex, 442, 445, 451, 452.  
 Augustins, royal convent of, at Madrid, 371.  
 Augustus, portico of, at Athens, 151.  
 Avington, church of, 389.  
 Axe, a carpenter's tool, 2003.  
 Ayot, St. Lawrence, church at, by Stuart, 516.  
 Aztec architecture, 110, 116.

## B.

Baalbec, extraordinary structures at, 196.  
 First described by Maundrel, *ib.*  
 Baalbec, niches at, 2775.  
 Babylon, ruins of, described, according to Rich, 38—41. Citadel of, 42. Tunnel under the Euphrates, 43. Dimension, rather than art, its character, 44.  
 Bacchus, Ionic temple of, at Teos, 153.  
 Back flaps of shutters, 2147.  
 Back linings of sash-frame, 2147.  
 Back of a slate, 2211.  
 Badajos, Giovanni di, a Portuguese architect, 367.  
 Bagdad, foundations of, laid by Almansor, 119.  
 Bagdad, its walls, 131.  
 Bagnall, Sir John, house for, designed by Thorpe, 440.  
 Baguette, 2532.  
 Balleso, Giovanni, a Spanish architect, 367.  
 Ballium of a castle, what, 394.  
 Balusters, 2695, *et seq.* Not used by ancients, 2696. Their measures, 2697. For Tuscan order and table of proportions, 2699, 2702. For Doric and Ionic orders, 2700. For Corinthian and Composite orders, 2701. Double-bellied, 2703. Double-bellied for Doric order, 2704. Double-bellied for Ionic order, 2705. Double-bellied for Corinthian order, 2706. Intervals between, 2708. Bulbs or bellies of, 2711. See also "Balustrades."  
 Balustrades and Balusters, 2695, *et seq.* Rules for setting out, 2697. Height of, 2698. At Chiericato palace, 2698. At Porti palace, *ib.* At Valmarana palace, *ib.* Scroll and Guiloche, 2707. Intervals in, 2708. Pedestals of, 2708, 2709. Applied to staircases, 2710. Statues used on, 2712. Vases used on, 2713. See also "Balusters."  
 Balustrades of arcade, 2657.  
 Bamborough Castle, 394, 398.  
 Bank of England, parts of, well planned, 2885.  
 Banker, bricklayer's, 1890.  
 Banqueting House, window at, 2762.  
 Baptistery at Florence, doors of, 2735.  
 Barbican of a castle, what, 394.  
 Barfreston, church of, 389, 391.  
 Bar iron, weight of a foot in length, 2254.  
 Barracks, 2982.  
 Bars with latchets, 2263.  
 Bartholomew's Hospital, by Gibbs, 503.  
 Basements and attics, 2665, *et seq.* Generally decorated with rustics, 2666. Courses of, how disposed, 2667. Rock-work in, 2670.  
 Bases of columns, origin of, 135.  
 Bases of columns, mode of gluing up, 2202.  
 Basilica of Antoninus, 2547.  
 Basilicæ, ancient, of Rome, 273—275. Plan and interior view of S. Paolo fuori la Murà, *ib.*  
 Basing House, date and founder, 449.  
 Bastard stucco, 2236—2243.  
 Bastille at Paris, 311.  
 Bat, defined, 1896.  
 Batalha, church of, 321. Described, *ib.*  
 Bath Abbey church, Appendix, p. 835.  
 Bath, city, many buildings there by Wood, 513.  
 Bath, conventual church of, founders and dimensions, 434.  
 Baths, number of, at Rome; those of Caracalla described, 234, 235. Of Titus, Diocletian, Agrippa, Nero, and Domitian, *ib.* Highly decorated with painting and sculpture, 237. Those of Agrippa, *ib.* None erected after the removal of the empire, 238. Of Titus, paintings in, 239. Of Caracalla, described, and plan of, 241. Alluded to, 282. Of Diocletian, 264, 2547. Of Nero, dimensions of, 240.  
 Battening of walls, how measured, 2338.  
 Battista, Giovanni, an architect of Toledo, 370.  
 Bay window, what, 427.  
 Bead or Baguette, 2532.  
 Bead and Butt, what, 2131.  
 Bead and double quirk, 2127.  
 Bead and flush, what, 2131.  
 Beaulieu, palace at, 426.  
 Beaumaris Castle, 402.

- Beaupré Castle, Gloucestershire, 452.  
 Beauty in architecture, partly from suitable forms, 2495. Sources of, 2492, *et seq.*  
 Beauvais Cathedral, north porch, Appendix, p. 830.  
 Bec, in Normandy, abbey at, 310.  
 Bed of a slate, 2211.  
 Bedding stone, 1890.  
 Bedford Castle, 394.  
 Beeston Castle, Cheshire, 391. 398.  
 Bellhanger's work, in specifications, 2292.  
 Bell metal, 1791.  
 Bells, introduced, 390.  
 Belus, tower of, described, 38. 41.  
 Belvedere Garden, arcade at, 2638.  
 Belvedere House, Kent, for Lord Eardley, by Stuart, 516.  
 Bench, joiner's, and parts of, 2102.  
 Bench planes, 2102.  
 Beni-hassan, tomb at, exhibits Doric column, 133.  
 Berkeley Castle, 394. 398. 414.  
 Berlin, Brandenburg, gate at, 366.  
 Bernardo Buontalenti, windows by, 2759.  
 Bernini, 347. His style considered, 348. Made designs for the Louvre, *ib.* Left design for façades of Louvre, and his disgust with workmen at Paris, 359.  
 Berruguette, a Spanish architect of the sixteenth century, 368.  
 Bethel and Bothel mentioned, 13. That set up by Jacob, *ib.* Object of idolatrous worship where the Canaanites appeared, *ib.*  
 Bevel, bricklayer's, 1890.  
 Beverley Minster, conventual church of, 407. 421. West front restored to perpendicularity, 449.  
 Biban el Melook, subterranean chambers of, 63.  
 Bibbiena, his theatres, 2950.  
 Bibliotheca of a Roman house, 252.  
 Bibliothèque du Roi, Paris, 2911.  
 Billet ornament, 397.  
 Binding joists, 2019—2022.  
 Birs Nemroud, near Babylon, as described by Rich, 40. The ruins spoken of by Père Emanuel, 40. 41.  
 Biscop, Benedict, founder of the abbey of Weremouth, 385, 386.  
 Blackfriars Bridge, by Mylne, 521.

 Ely House, Dover Street, by Taylor, 515.  
 Engaged pilasters, Burlington House, 2615.  
 England, Saxon churches of, 290.  
 English bond, 1892. 1894.  
 Enrichments in plastering, 2250.  
 Entablature, height of, 2523, *et seq.*, 2542. 2544.  
 Entablatures, subdivision of, 2549.  
 Entasis, or swelling of columns, first verified by Mr. Allason, 144. Explanation of the object of it, *ib.*  
 Entasis, 2545.  
 Eopylæ, Appendix, p. 824.  
 Eosander, a German architect, 365.  
 Eotholæ, Appendix, p. 824.  
 Ephebeum of the Greek gymnasium, 175.  
 Of the Roman baths, 235.  
 Episcenium of the Greek theatre, 172.  
 Equations, simple, resolution of, 816—824.  
 Resolution of two or more of the first degree, 825—832. Of pure quadratic equations, 833—841. Of mixed, of the second degree, 842—848. Of complete equations of the third degree, 849—860.  
 Equilateral triangle applied to buildings, Appendix, p. 821.  
 Equilibrium necessary for fitness, 2500.  
 Erectheus, Ionic temple of, at Athens, 155.  
 Erwin of Steinbach, architect of cathedral at Strasburg, 305.  
 Escorial, designs for, by Giovanni Battista of Toledo, 370, 371. Cause of its erection, *ib.* Described, *ib.*  
 Esher, in Surrey, palace at, 426.  
 Esneh, ruins at, 71.  
 Estimating, 2295, *et seq.*  
 Eaton College Chapel, 421.  
 Etruscan architecture, probably a branch of the Cyclopean, 178. Marked by great solidity of construction, 179.  
 Euclid's Elements early used, Appendix, p. 819.  
 Eudes de Montreuil, architect, 310.  
 Eustyle intercolumniation, 2605—2611.  
 Evreux Cathedral, Appendix, p. 830.

Examples of the Florid or Tudor style, 432.  
 Excavator's work in specifications, 2281.  
 Exchanges, 2937, *et seq.* Definition of, 2937. How sometimes designed, 2938.  
 That of Amsterdam, 2939. Sir Christopher Wren's opinion relative to, 2940.  
 New Royal Exchange, 2941. That at Paris described, 2943.  
 Exedra of the Greek gymnasium, 175. Of the Roman baths, 235.  
 Exedrae of a Roman house, 252, 253.  
 Exeter Castle gateway, 391.  
 Exeter Cathedral, founders and dimensions of, 434.

## F.

Façade of Nero at Rome, 262.  
 Falling mould of stairs, 2188.  
 Fancelli and Michelozzo, scholars of Brunelleschi, 323.  
 Fancy colours in painting, 2272—2276.  
 Fan vaults, Appendix, pp. 833, *et seq.*, 837.  
 Farm-houses, 3002, *et seq.* Distribution of, 3003. On large scale, 3004.  
 Farnese Palace cornice, 2725. Door at, 2741.  
 Farnese Palace, door at, by Vignola, 2741. Window at, 2763.  
 Fauces of a Roman house, 250, 253.  
 Fex, ancient Arabian city, described generally, 132.  
 Fiesole, walls of, 179.  
 Figures in decoration, 2519, 2521. Similar, 958—968.  
 Filippo, Mastro, a Spanish architect, 367.  
 Fillet, Listel, or Annulet, 2532.  
 Fillets, 2129.  
 Fine stuff, plasterer's, 2236.  
 Fischers, a German architect, 365.  
 Fitness, the basis of proportion, 2496, 2497. Dependent on equilibrium, 2500. Maxims relating to, 2502.  
 Fitzwilliam, Mr. William, house designed for, by Thorpe, 440.  
 Flamboyant style, Appendix, p. 829, *et seq.*  
 Foliage in, 830. Sculpture in, *ibid.*  
 Flashings, in plumbery, 2213.  
 Flemish bond, 1892, 1897.  
 Flemish bricks, 1830.  
 Fliers, in stairs, 2186.  
 Flitcroft, Henry, an architect, *temp.* George II., 512.  
 Float stone, bricklayer's, 1840.  
 Floated work, plasterer's, 2242.  
 Flooring and floors, 2013—2023. Single, 2014, *et seq.* Constructed with short pieces of timber, 2023. Boards, value of labour of, 2368.  
 Flooring, value of labour of, 2350.  
 Floors, 2168—2173.  
 Floors, variable loads on, and largest weight placed on, 1778.

 Hever Castle, Kent, 426.  
 Hexastyle temples, 2528, *et seq.*  
 Hexham, cathedral at, 385.  
 Hieroglyphics in Egyptian architecture, 86.

- Ifingham Ferrars, parochial church of, 408.  
 421.  
 High Church, Edinburgh, alluded to,  
 485.  
 Hill Hall, Essex, 426.  
 Hingeing, 2149—2163.  
 Hinges, different sorts, 2258.  
 Hiorne, an architect, *temp.* George III.,  
 his works, 514.  
 Hip rafter, what, 2009.  
 Hip rafters, 2035.  
 Hip tiles, 1836.  
 Hips, to find back of, 2054.  
 Hod and board, slater's, 2210.  
 Hod, bricklayer's, 1890.  
 Holbein, Hans, and his design of Whitehall  
 Palace, 427.  
 Holdenby, designed by Thorpe, for Sir  
 Christopher Hatton, 440.  
 Holkham, 2997.  
 Holkham, excellent distribution of plan,  
 2822.  
 Holkham, in Norfolk, by Kent, 511.  
 Holland, architect, *temp.* George III., 521.  
 Holland House, Kensington, built by  
 Thorpe for Sir Walter Cooper, 440. 452.  
 Hollow, 2532.  
 Hollow bricks, 1829.  
 Holte, Sir Thomas, ground-plan for, 440.  
 Holte, Thomas, architect of public schools  
 at Oxford, 443.  
 Holy Apostles, church of, at Constanti-  
 nople, 271.  
 Holyrood Chapel, finished by James II. of  
 Scotland, 431.  
 Hou, of the Chinese, 106.  
 Hontanon, an architect of Spain, 15th cen-  
 tury, 367.  
 Horse Guards, designed by Kent, 511.  
 Horseheath House, Cambridgeshire, by  
 Webb, 465.  
 Hospitals, 2973, *et seq.* What, 2973. Not  
 known to the ancients, 2974. Examples  
 of, in Durand's *Parallèle des Edifices*,  
 particularly that at Milan, 2975. Of  
 Greenwich and Chelsea, 2976.  
 Hospitium of a Roman House, 251.  
 Hotel des Ambassadeurs, Dijon, Appendix,  
 p. 848. De Bourgtheroude, Rouen, Ap-  
 pendix, pp. 851, 852. De Cluny, Paris,  
 Appendix, p. 853.  
 Hotel des Invalides at Paris, 359.  
 Hotels de Ville, Bruges, Appendix, p. 855.  
 Brussels, pp. 848, 855, 856. Ghent, p.  
 857. Louvain, pp. 856, 857. Orleans,  
 p. 850. St. Quentin, p. 849.  
 Houghton Hall, water-house at, by Earl  
 of Pembroke, 508.  
 House of the Forest of Lebanon, 53.  
 Houses, first, according to Vitruvius, 5.  
 First, of the Egyptians, Peruvians, *ib.*  
 Present, of the Abyssinians, *ib.* In the  
 East, consisting of more than a single  
 story, 140. Terrace on the tops of them,  
*ib.*  
 Housing, principal rafters, 2033.  
 Howard, Earl of Northampton, present  
 Northumberland House built for, 442.  
 Howden, conventual church of, 407. 421.  
 Hull, brick used early as a material at,  
 416.  
 Hültz, John, of Cologne, engaged on ca-  
 thedral at Strasburg, 305.  
 Human figure, proportions of, 2394. Ac-  
 tions of, 2396, *et seq.* Centre of gravity  
 of, *ib.* Motion of, 2397. In running,  
 2398. In preparing to strike, 2399. In  
 bearing a weight, 2400. In leaping,  
 2401. In leaning, 2402. In flying and  
 falling, 2403.  
 Hundred of lime, how much, 2303.  
 Hunsdon House, date and founder, 446.  
 Palace at, 426.  
 Hurlers, the, circle of stones in Cornwall,  
 16.  
 Hurstmonceaux in Sussex, 423.  
 Hyperbola, 1083—1094.  
 Hypnerotomachia, 326.

## I.

- Ifley Oxon, parochial church of, 398.  
 Ilyssus, Ionic temple, on the, 153.  
 Imaginary quantities, 593—600.  
 Imperial slates, 1804.  
 Impluvium of a Roman house, 247.  
 Impossible quantities, 593—600.  
 Imposts and archivolts of arcades, 2632.  
 Imposts, pendent, Appendix, pp. 833, 834.  
 837.  
 Inch tool, mason's, 1910.  
 Inclination of roofs in various climates,  
 2027—2030.  
 Inclined plane, 1293—1306.  
 Indian architecture, similarity of, to Perse-  
 politan, 55. Sir William Jones's opinion,  
 on, *ib.*  
 Indra Subba, column of, *ib.* Apartment of,  
 56.  
 Indra, temple of, at Ellora, *ib.*  
 Infinite decimal fractions, 783—796.  
 Ingelramme, employed on cathedral of  
 Notre Dame at Rouen, 516.  
 Inigo Jones, 425.  
 Inigo Jones, door by, 2743.  
 Inigo Jones, window by, 2770.  
 Inside bead of sash frames, 2147.  
 Inside linings of sash frames, 2147.  
 Insula in Roman domestic architecture,  
 what, 253.  
 Integers, properties of, as respects their di-  
 visors, 540—548.  
 Interaxial divisions in a design, 2842. Pre-  
 vent false bearings, 2843. Applied to  
 the Villa Capra, *ib.* Great use in, 2844.  
 Used by Gothic architects, 2845. Ob-  
 ligations to Durand for introduction of,  
 2846. Number of, in different apart-  
 ments, 2848. Columns of, how arranged  
 in apartments, 2849. Applied in de-  
 signing churches, 2875.

Intercolumniation, 2605, *et seq.* Different species of, *ib.* Of the Doric order, *ib.* Of the Tuscan order, 2606. Of the Ionic order, 2607. Of the Corinthian order, 2608. Vignola's practice, 2610. Cases of wide, 2613. Araostyle, 2613. To be of equal width, 2614—2616.

Interest, calculation of, 797—810. Solution of problems in, 811—815.

Interiors of buildings, beauty of, 2504, 2505.

Interpenetration of mouldings, Appendix, pp. 831, 832.

Intertie of a partition, 2025.

Invalids, hospital of, at Paris, points of support of, 1581.

Inverted arches in foundations, 1885.

Ionic arcade, 2624. With pedestal, 2630.

Ionic order, intercolumniations of, 2607.

Ionic order, origin of, according to Vitruvius, 140. 2573, *et seq.* Vignola's profile of, 2574. Table of parts of, *ib.* Parts of, to a larger scale, 2575. Volutes of, described, 2576. Profile of, by Vitruvius, 2577. By Palladio, 2578. By Serlio, 2579. By Scamozzi, 2580. Grecian, principal examples of, 2581. In the temple on the Ilyssus, *ib.* Table of the parts in the temple on the Ilyssus, *ib.*

Ionic order of the Greeks, height of its columns, 154. Entablature, *ib.* Bases of, 156. Volute of, 157.

Ionic order of the Romans, 260. Table of examples, *ib.* General proportion of, 261.

Ipswich, college at, 426.

Irish, a colony of the first race of people, 11.

Iron, 1754—1780. Three species of the ore, 1755. Mode of smelting, 1756—1759. Manufacture of bar iron, 1760, 1761. Malleable iron, 1762. Founding, 1764—1766. Security for supporting weight, 1767. Soft grey, best sort, 1768. Test of goodness of cast, 1769. Varies in strength, 1770. Transverse strength of, 1771—1774. Points relative to loads on beams of, 1775—1777. Cohesive strength of, 1779, 1780. Weight of cast and bar, 1780.

Ironmonger's work, in specifications, 2286.

Ironmongery and smithery, 2253.

Iron work, how preserved from action of moisture, 2264.

Irrational numbers, 583—592. 601—605.

Irrational powers, expressed by infinite series, 712—718.

Irrational quantities, calculation of, 693—698.

Italian architecture, 323, *et seq.*

Italy, principal cathedrals of, and their dates, 318.

Ivan IV. of Russia, a great patron of the arts, 375.

Ivan Valiki, celebrated clock tower in Moscow, 375.

Ivara, Filippo, a very celebrated architect of Spain, 372.

## J.

Jacchetti, a pupil of Ivara, a Spanish architect, 372.

Jack plane, plumber's, 2212.

Jack rafters, 2035.

James, John, an architect of reputation, *temp.* George I., 505.

Jammet, Mons., house at Paris, design for, by Thorpe, 440.

Jannin House near Paris, design for, by Thorpe, 440.

Jansen, Bernard, an architect, *temp.* Elizabeth, 442.

Jedburgh Abbey, 431.

Jerusalem, temple of, constructed by Solomon, described; curious notion about, of Villalpanda, 52. A small building, *ib.* Its columns, *ib.*

Jib door, what, 2130.

Joffred, abbot of Croyland, 392.

Joggles in carpentry, 2009.

Joggles in stone stairs, 1927.

John of Gaunt's gateway at Lancaster Castle, 416.

John of Padua and his followers, 425.

John VI. (Pope), arts under, 281.

Joiner's work and mode of measuring, value of labour of, 2351—2369.

Joinery, articles valued by running foot, value of labour of, 2368.

Joinery, 2100, *et seq.* Defined, 2100. Tools used in, 2102—2124. Mouldings, 2126—2129. Wood used for, 2124. Doors, 2130—2145. Shutters, 2146—2148. Hingeing, 2149—2163. Sash frames and sashes, 2164, 2165. Grounds, 2166, 2167. Floors, 2168—2173. Framing, 2174, 2175. Stairs, 2176—2186. Hand-rails and curtail steps, 2187—2192. Formation of bodies by joining with glue, 2193—2208.

Joiner, bricklayer's, 1890.

Joining rule, 1890.

Joists. See under their several heads of "Ceiling," "Binding," "Bridging," "Trimming," "Common," &c.

Jones, Inigo, account of, and his works, 454—464, inclusive.

Julian patronised the art, and extent of his patronage, 203.

Juno, Ionic temple of, at Samos, 153.

 Le Veau, Louis, associated with Perrault in building the Louvre, 359.  
 Level, bricklayer's, 1890.  
 Lever, properties of, 1265—1269.  
 Lias, blue, 1843.  
 Libraries. See "Public Libraries."  
 Lichfield Cathedral, 421. Founders and dimensions of, 434.  
 Lichfield Chapter-house, doorway, Appendix, p. 844.  
 Liernes, Appendix, p. 835.  
 Light, area of, in Pantheon at Rome, 2747.  
 Lighthouses, 2924, *et seq.* Built at an early period, 2925. Jacob Bryant on, 2926. Pharos of Alexandria, 2927. Of Corduan, 2929. Eddystone, 2930. North Foreland, 2931.  
 Lights, leadwork for, 2227.  
 Ligorio, Pirro, architect of the Villa Pia at Rome, 345.  
 Lime, measures of, 2303.  
 Lime, 1840—1857. What, 1840. Varieties of limestone, 1841, 1842. Dorking and Merstham lime, 1843. Lias of So-

- mersetshire, *ib.* Of Sunderland, *ib.*  
 South Shields, *ib.* Brown most esteemed,  
 1844. Limestone, how to analyse, 1845.  
 Burning, 1846, 1847. Best that which  
 heats most in slaking, 1849. Use of fresh,  
 1850. Limestones examined by Smeaton,  
 1851. Forming mortar from, 1852—1857.  
 Proportion of, to sand, 1853.  
 Lincoln Castle, 394, 398.  
 Lincoln Cathedral, 396, 406, 421. Founders  
 and dimensions of, 434.  
 Lincoln Chapter-house, Appendix, p. 837.  
 Lindisfarne, church built at, 388.  
 Line pins, bricklayer's, 1890.  
 Linings, value of labour of, 2368.  
 Listel or Annulet, 2532.  
 Llanphepy Court, castellated palace at, 413.  
 Llantony, conventual church of, 398.  
 Loads and supports in an order, equality  
 of, 2524. Principles of proportion for  
 the orders, 2525, *et seq.* In tetrastyle,  
 hexastyle, and octastyle temples, 2528.  
 Concordance with the laws given by Vi-  
 truvius, 2529. Ancient examples of,  
 2531. Principles applied to points of  
 support, *ib.*  
 Lock rails of a door, 2150.  
 Locks, different sorts, 2261.  
 Logan or rocking stones, celebrated one in  
 Cornwall, 25.  
 Logarithmic tables, 639, 640.  
 Logarithms, 632—638. Method of ex-  
 pressing, 641—654.  
 Λογίων, of the Greek theatre, 172.  
 Lomazzo, his work translated into English,  
 438.  
 Lombards overrun Italy, their civilisation  
 and works, 280.  
 London buildings, commission *temp.*  
 James I. to prevent, on new foundations,  
 457.  
 Longford Castle, Wilts, designed by  
 Thorpe, 440, 452.  
 Longleat House, date and founder, 446.  
 Long Meg and her daughters, circle of, in  
 Cumberland, 16.  
 Lorient's cement, 1865.  
 Lorsch, convent of, 283.

 Manchester College, 421.  
 Manorial houses, of timber, short account  
 of, 439.  
 Mansard roof, 2035.  
 Mansart, Jules Hardouin, architect in  
 France, *temp.* Louis XIV., 359.  
 Mansions, few of the Tudor age now exist,  
 429.  
 Marble Hill, Twickenham, by Earl of Pem-  
 broke, 508.  
 Marble, what, 1673. External characters  
 and constituent parts, 1674. May be  
 burnt into quicklime, 1675. Different  
 varieties of ancient and modern, 1676—  
 1683.  
 Margins of the xystus, 175.  
 Marl stocks, 1821.  
 Marsh, an architect mentioned by Vertue,  
 465.  
 Mars Ultor, Corinthian temple of, at Rome,  
 210.  
 Martinelli, employed in Germany, 365.  
 Mason's marks, Appendix, pp. 821, 822.  
 Mason's work, in specifications, 2284.  
 Mason's work, how measured, 2370. Values  
 of labour of, 2373.  
 Masonry, 1909—1956. What, 1909. Tools  
 used in, 1909, 1910. Stone walling, 1916  
 —1924. Footings of stone walls, 1916.  
 Foundations of same, 1917. Rubble  
 walls, *ib.* Ashlar facing, 1918, 1919.  
 Columns, 1925. Stairs, 1926—1929.  
 Geometrical stairs, 1927—1929. Scien-  
 tific operations of stone-cutting, 1930, *et*  
*seq.* Construction of arches and simple  
 vaults, and their groins, 1931. To draw  
 elliptic arch and find the joints, 1934—  
 1937. To draw Gothic arch and find  
 joints, 1938—1941. To draw rampant  
 Gothic arch and find the joints, 1943.  
 Construction of intersecting vaults and  
 groins, 1944, *et seq.* Dome vaulting, 1956,  
*et seq.*  
 Masques, decorations for, designed by Inigo  
 Jones, 460.  
 Massimi Palace, arcade at, 2635.

- Materials, crushing weight of, 1500.  
 Mathematics, generally defined, 523.  
 Mattei Palace at Rome, windows at, 2758.  
 Mausoleum of King John, Portugal, 321.  
 Mayence, cathedral of, 287, 288.  
 Measuring and estimating, 2295, *et seq.*  
 Measuring brickwork, 2295, *et seq.*  
 Measuring digging, 2298.  
 Measuring rule, plumber's, 2212.  
 Measuring tiling, 2301, *et seq.*, 2316.  
 Mecca, houses, how built, 131.  
 Mechanical arts, not absolutely necessary to progress of architecture, 9.  
 Mechanical carpentry, 1598—1635. Woods used in, 1593—1595. Weights of wood in the same tree, 1597. Timber, experiments on, 1598, *et seq.* Cohesive force of timber in direction of its length, 1598. Strength of wood in an upright position, 1600—1602. Horizontal pieces of timber, 1603—1613. Tables of experiments on timber, 1613—1624. Tables applied to other timber besides oak, 1624—1635. Method of using tables for horizontal timbers, 1625, 1626. The same for vertical bearing timbers, 1627—1629. The same for obtaining the absolute or cohesive strength, 1630—1632. Strength of timbers in an inclined position, 1633—1635.  
 Mechanics and statics, general observations and definition, 1240—1243. Parallelogram of forces, 1244—1259. Of the lever, 1260—1265. Centre of gravity, 1266—1268. Centre of gravity of lines, 1269—1274. Centre of gravity of surfaces, 1275—1280. Centre of gravity of solids, 1281—1290. Centre of gravity of irregular solids, 1291, 1292. Of the inclined plane, 1293—1306. Of the wheel and axle, 1307—1314. Of the pulley, 1315—1320. Of the wedge, 1321—1323. Of the screw, 1324—1330. Of friction, 1331—1341. Values of moving powers, 1342—1352.  
 Mediæval architecture, division of styles, Appendix, p. 830.  
 Medicean Library at Florence, 2910.  
 Meilan, Chateau de, Appendix, p. 853.  
 Melrose Abbey, 431.  
 Melton Mowbray, parochial church of, 421.  
 Melton, parochial church at, 398.  
 Members, what, 2129.  
 Memnonium, statues of, described, 85.  
 Menilmontant, abattoir of, at Paris, described, 2935.  
 Mensuration, defined, 1212, 1213. To find the area of a parallelogram, 1214. To find the area of a triangle, 1215. To find the area of a trapezoid, 1216. To find the area of any trapezium, 1217. To find the area of an irregular polygon, 1218. To find the area of a regular polygon, 1219. To find the diameter and circumference of a circle, 1220. To find the length of any arc of a circle, 1221. To find the area of a circle, 1222. To find the area of a circular ring, 1223. To find the area of the sector of a circle, 1224. To find the area of the segment of a circle, 1225. To find the area of an ellipse, 1227. To find the area of a parabola or its segment, 1228. Of solids, 1229—1239. To find the superficies of a prism, 1231. To find the surface of a pyramid or cone, 1232. To find the surface of the frustum of a pyramid or cone, 1233. To find the solid content of any prism or cylinder, 1234. To find the content of any pyramid or cone, 1235. To find the solidity of the frustum of a cone or pyramid, 1236. To find the surface of a sphere or any segment, 1237. To find the solidity of a sphere or globe, 1238. To find the solidity of a spherical segment, 1239.  
 Merab, extraordinary reservoir of, 118.  
 Mereworth, in Kent, by Campbell, 504.  
 Mereworth, villa at, 3000.  
 Merton College Chapel, Oxford, 421.  
 Meta of the Roman circus, 240.  
 Metopæ, origin of, 135.  
 Meulan, Waltier de, employed on Abbey of Bec, in Normandy, 310.  
 Mexican pyramids, 111, 112.  
 Mexico, city of, described generally, 117.  
 Mews, late at Charing Cross, arcade at, 2635.  
 Miao, or idol temples in Pekin and environs, 104.  
 Michel Angelo, door by, 2740.  
 Michelozzo, pupil of Brunelleschi, 323.  
 Middleburg, in Yorkshire, 423.  
 Middleham Castle, 398.  
 Middle panels of a door, 2130.  
 Middle rails of a door, 2130.  
 Middle stiles of a door, 2130.  
 Milan, cathedral at, described, 318, 322.  
 Milan, hospital at, 2975.  
 Milan Theatre, 2958—2967.  
 Military architecture, from Edward III. to close of York and Lancaster contention, 413.  
 Milled lead, 1783.  
 Milton Abbey, Dorset, conventual church of, 407.  
 Minaret, introduced by Alwalid II., 119.

 Norman architecture, 383. 392, *et seq.* Characteristics of, 397. Examples of, 398.  
 Norman bishops, and their works, 396.  
 Norman cathedrals, 396.

Norman churches, 290.  
 Norman columns, 397. Arches, *ib.* Arches of entrance, *ib.* Windows, *ib.* Ceilings, *ib.* Walls, *ib.* Ornaments, *ib.* Plans, *ib.*  
 North Foreland lighthouse, 2931.  
 Northumberland House, by Christmas and Jansen, 442.  
 Norwich Castle, 393, 394.  
 Norwich Cathedral, 398. 421. Founders and dimensions of, 434.  
 Nosing of stairs, 2180.  
 Notre Dame de bonnes Nouvelles, at Orleans, *ch. 2*, 289.  
 Nottingham Castle, 423. Works by Marsh, 466.  
 Nubia, temples and remains of, 92.  
 Nymphaea Lotus, or water-lily, source of Egyptian ornament, 87.

## O.

Observatories, 2920, *et seq.* At Paris, 2920. A regular observatory, what, 2921. That at Edinburgh described, *ib.* Piers of, how constructed, 2922. That of Sir James South, *ib.* Situations of, should be dry, 2923.  
 Observatory at Paris, built by Perrault, 359.  
 Octastyle temples, 2528, *et seq.*  
 Odilo, abbot, commenced cathedral at Chartres, 289.  
 Odoacer, annihilation of the arts on invasion of, 276—278.  
 Œcus of a Roman house, 252. Several species of, *ib.* That called Cyzicene, *ib.*  
 Œillet holes, at Carnarvon Castle, 402.  
 Offices of government. See "Government Offices."  
 Ogee, 2129.  
 Old Louvre, windows from, 2760.  
 Old Somerset House, ground plan, 440.  
 Olotzaga, an early architect of Biscay, 367.  
 Oppenheim, church at, dedicated to St. Catherine, described, 304.  
 Orchestra, of a Roman theatre, 226. Of the Greek theatre, 172.  
 Order, Tuscan. See "Tuscan Order." Doric, see "Doric Order."  
 Orders above orders, 2642, *et seq.* Vitruvius thereon, 2643. Scamozzi's rule, 2644. Laws of solidity respecting, 2645. Axes of upper and lower columns, how placed, 2646. Disposition of, according to Chambers, 2647, *et seq.* Doric above Tuscan, 2648. Ionic above Doric, 2649. Corinthian above Ionic, 2650. Composite above Corinthian, 2651. Most eligible intercolumniations, 2652.  
 Orders, character of the different, 2538, *et seq.* Doric, Ionic, and Corinthian, 2539. Sir Henry Wotton's description of them, 2540. Invention of new ones, 2541. Entablatures, height of, in, 2542.  
 Orders, mode of measuring them, 2550. Application of, 2552.

Orders of architecture, 2523, *et seq.* Consist of essential and subservient parts, 2523. Are five in number, *ib.* Mode of profiling an order, *ib.* Lebrun's analysis of loads and supports in an order, 2524. Principles of proportion as to loads and supports, 2525, *et seq.* Systylos intercolumniation produced by such principles, 2527. Principles of load and supports carried into tetrastyle, hexastyle, and octastyle temples, 2528, *et seq.* Concordance thereof with the laws given by Vitruvius, 2529. Ancient examples of different orders in verification of the theory, 2531. Principles applied to points of support, *ib.* Tuscan, 2553. Doric, 2560. Ionic, 2573. Corinthian, 2582.  
 Composite, 2591.  
 Orford Castle, 398.  
 Orgagna, loggia of, at Florence, plan and elevation, 327.  
 Oriel window, where used in halls, 415.  
 Orleans, churches at, 289.  
 Orleans, Hotel de Ville, Appendix, p. 850.  
 Ornament, a non-essential in architecture, 2826.  
 Ornamented English architecture, 409, *et seq.* Subdivided into two æras, 410. Flourished notwithstanding civil wars, 411. Characteristics of, 420. Examples of, 421.  
 Ornaments of mouldings, how to arrange, 2535. How to be cut, 2536. Degree of relief they should have, 2537.  
 Ornaments of the Grecian edifices suitable to their destination, 164.  
 Orvieto, cathedral at, 318.  
 Osterley House, date and founder, 446. Anecdote relating to, 447.  
 Ostiarius of a Roman house, where stationed, 246.  
 Osymandyas, tomb of, according to Dioscorus, 85.  
 Outline, the fundamental principle of drawing, 2386.  
 Outside linings of sash frames, 2147.  
 Outside stiles of a door, 2130.  
 Ovens, &c., how measured, 2314.  
 Ovolo, 2129. Echinus or quarter round, 2532.  
 Oxford Castle, 394. 398.  
 Oxford, palace at, 423.  
 Oxford, public schools of, designed by Holte, 444. First who introduced the classical orders, 444. 451.

## P.

Packing, in masonry, 1921.  
 Pæstum, great hypæthral temple of, 149.  
 Page, Sir Gregory, house for, at Blackheath, by James, 505.  
 Pagodas, or Chinese towers, that of Nan-king described, 105. That of Honang, in the southern suburb of Conan, at Canton, described, 104.

- Paine, an architect, *temp.* George III. His works, 514.
- Painter's tools, 2268.
- Painter's work, in specifications, 2290. Method of estimating, 2379.
- Painting and sculpture, intimately connected with architecture, 68. Much used in ornamented English architecture, 412.

 Roman temples of the quadrangular species, 208, *et seq.* Of the circular species, 214, *et seq.*, 217.  
 Romanesque or Byzantine architecture, 270, *et seq.*  
 Romanesque style, Appendix, p. 830.  
 Romans, private houses of, 245.  
 Rome, palaces of, 343, 344.  
 Rome, principal churches of, and their character, 342.  
 Rome taken by Totila, and again united to Eastern Empire, 279.  
 Roof, examination of strains in, 2031. Tie beam, *ib.* Collar beam, *ib.* Sagging, how prevented, *ib.* King post, what, *ib.* Truss, what, *ib.* Struts, what, *ib.* Principal rafters, framing of, 2033. Queen posts, 2034. Straining piece, *ib.* Mansard roof, 2035. Common rafters in, *ib.* Purlin, *ib.* Pole plates, *ib.* Ridge piece, *ib.* Hip rafters, *ib.* Jack rafters, *ib.* Scantlings of timbers for different spans, 2037—2040. Mode of framing for different spans, 2042—2045. Of St. Martin's-in-the-Fields, 2046. Of chapel at Greenwich Hospital, 2047. Of old Drury Lane Theatre, 2048. Dome of St. Paul's, 2049. Roof of St. Paolo fuori le Mura, 2051. Delorme's mode of framing domes, 2052. Lines for framing, 2053. Hips, to find the back of, 2054. Lines of, to find, 2053—2057.  
 Roofing, how measured, 2337.  
 Roofing, value of labour of, 2350.  
 Roofs of the edifices of Athens and Rome, 176.  
 Roofs, proper inclination of, in various climates, 2027—2030.  
 Rooms, proportions of, 2820, *et seq.* Height of, 2821. Height of galleries, 2822. Palladio's rules, 2823, 2824.  
 Roots, relatively to powers, 617—620. Of compound quantities, 688—692.  
 Rosellini, Bernardo, employed by Julius II. for restoring basilica of St. Peter's, 335.  
 Roslyn Chapel, erected by Sir William St. Clair, 431.  
 Rouen, cathedral of Notre Dame at, 310.  
 Rouen, Palais de Justice, Appendix, pp. 850—852. Hotel Bourghtheroude, pp. 851. 852.  
 Roughcast, 2249.  
 Royal Exchange, new, 2941—2943.  
 Rubbed returns, 1890.  
 Rubbing stone, bricklayer's, 1890.  
 Rubble wall defined, 1917.  
 Rudstone Pillar, in East Riding of Yorkshire, 14.  
 Ruiz, Ferdinand, a Spanish architect, 368.  
 Rule, glazier's, 2226.  
 Rumsey, church of, in Hampshire, 396.  
 Russian architecture, 374, *et seq.* Ecclesiastical, coeval with the introduction of Christianity in the country, 375. Churches built in the eleventh century, 375.  
 Russian churches, type of, 377.

S.

Sacrificial stones, what, 22.  
 Saffron Walden, parochial church at, 421.  
 Sagging prevented, 2031.

- Saint Mark, at Venice, library of, 357.; and elevation of, *ib.*  
 Salamanca, cathedral at, 367.  
 Salisbury Cathedral, 314. And Rheims compared, 315. Comparison with that of Amiens, 315. Founders and dimensions of, 434.  
 Salisbury Chapter-house, Appendix, p. 837.  
 Salsette, excavation of, near Bombay, 57.  
 Salzburg Cathedral, designed by Scamozzi, 355.  
 San Carlos, theatre of, at Naples, 2967.  
 Sand, measures of, 2304.  
 Sand, river, 1858. Pit, 1859.  
 Sanding, in painting, 2277.  
 San Domenico di Silos, church and monastery of, 369.  
 San Domenico, Palermo, walls at, 1535.  
 San Fantino, at Venice, church of, 351.  
 Sangallo, consulted on building St. Peter's, 335. Architect of Farnese Palace, 343.  
 San Giovanni Battista, near Toledo, hospital of, 370.  
 San Giovanni Laterano, doors of, 2735.  
 San Lorenzo fuori le Mura, at Rome, church of, 281.  
 San Martino, gate of, at Toledo, 368.  
 San Micheli, some account of, and his works, 350. A military architect, *ib.*  
 San Paolo fuori le Mura, at Rome, church of, 281.  
 San Salvatore, at Venice, Scamozzi employed on, 355.  
 Sansovino, some account of, and his works, 351. His architectural problem of the Doric frieze, 365.  
 Santa Croce, college of, at Valladolid, 367.  
 Santa Engracia at Saragossa, 367.  
 Saracenic or Arabian architecture, 118, *et seq.* Decline of, 128.  
 Sarum, old, cathedral, 396.  
 Sash frames and sashes, 2164, 2165.  
 Sash lines and weights, 2263.  
 Sash tools, glazier's, 2226.  
 Sashes and frames, value of labour of, 2368.  
 Savoy, palace at, 423.  
 Saw, a carpenter's tool, 2003.  
 Saw (the), not known to the Greeks, 7.  
 Saws, ripping, half-ripper, hand, panel, tenon, sash, dovetailed, compass, keyhole or twining, 2115. Teeth of, 2116.  
 Saxon and Norman styles, difference between, 397.  
 Saxons, arrival of, in Britain, 383.  
 Scales and weights, plumber's, 2212.  
 Scamozzi, Vincenzo, some account of, and his works, 355. His plan for Piazza San Marco, *ib.* Employed at Salzburg, 365.  
 Scantle, what, 2210.  
 Scantlings for joists, 2015—2022. For girders, 2021.  
 Scarfing, 2007.  
 Schönbrunn, palace at, 365.  
 Sciography, 2458—2484. See "Shadows."  
 Scotia or Trochilos, 2532.  
 Scotland, architecture of, in time of the Saxons, 383. 388. Stone buildings in, of high antiquity, 388.  
 Scotland, Tudor examples of style in, 431.  
 Screw, 1324—1330.  
 Screw check, what, 2102.  
 Screws, 2257.  
 Scribe, bricklayer's, 1890.  
 Sculpture much used in the early English style, 401.  
 Sculpture rather than painting allied to architecture, 2522.  
 Seams in plumbers, 2213.  
 Secular architecture of France, Appendix, p. 847.  
 Segments of a circle, table of areas when the diameter is unity, 1225.  
 Segovia, bridge of, at Madrid, 371.  
 Segovia, cathedral of, 367.  
 Selby, conventual church at, 398.  
 Selby, Yorkshire, conventual church of, 421.  
 Selinus or Selinuns, city of, in Sicily, 147.  
 Semiramis, works of architecture attributed to, 9.  
 Semitæ of the xystus, 175.  
 Seraglio, reception room of, 132.  
 Serlio, door by, 2744.  
 Servandoni, an Italian architect, employed on St. Sulpice, at Paris, 362.  
 Service pipes, 2215.  
 Setting board, glazier's, 2228.  
 Setting knife, glazier's, 2228.  
 Severeys, what, 415.  
 Seville, cathedral at, 320. 368.  
 Sewers, 3008.  
 Sewers, their importance, size, and proper form, 1887, 1888.  
 Seyssel's asphalt, 1879.  
 Shade, as distinguished from shadow, 2459.  
 Shadows, method of projecting in architectural drawings, 2458—2484. Angle usually employed for the light, 2459—2462. Examples, 2464, *et seq.* Shadows on steps, 2468. Of modillions, 2469—2471. On triglyphs, 2472. Of consoles, 2473. Of niches, 2475. Of pediments, 2476. Of bases, 2480. Of Tuscan, Ionic, and Corinthian capitals, 2480—2484.  
 Shaftesbury House, Aldersgate Street, by Jones, 462.  
 Shafts of columns, Appendix, p. 839.  
 Shafts, bases of Attic, in eleventh and twelfth centuries, Appendix, p. 839.  
 Shah Abbas, caravanserai of, described, 51.  
 Shah Meidan, at Ispahan, described, 51.  
 Sheet-lead, 1783.  
 Shene, in Surrey, palace at, 424.  
 Sherbourn Minster, Dorset, 398.  
 Sheriff Hutton, Yorkshire, palace at, 426.  
 Shooting, what, 2102.  
 Shute, John, author of earliest publication in the English language on architecture, 438. Patronised by Dudley, Earl of Northumberland, *ib.*

- Shutter bars, 2263.  
 Shutters, 2146—2148. Value of labour of, 2368.  
 Σκηνη, or Scena, of the Greek theatre, 172.  
 Skew back, 1890.  
 Skirts of a roof, 2053.  
 Skylights, value of labour of, 2368.  
 Sicily, Grecian temples of, 147.  
 Side boards, what, 2102.  
 Side nook, 2121.  
 Siena, cathedral at, 318.  
 Signia, Cyclopean remains at, 32.  
 Signs, in algebra, 524—526.  
 Sill of a partition, 2025.  
 Siloe, a Spanish architect, 368.  
 Similar figures, 958—968.  
 Sine of an arc, 1039.  
 Single flooring, 2013.  
 Single stones, early practice of erecting, and of what probable emblem, 13.  
 Sion House, Middlesex, completed for Henry, Earl of Northumberland, 442.  
 Slate, 1798—1810. Description of, 1798. Whence brought to London, 1799. Species of, *ib.* Desirable properties of, 1800. Tests of quality of, 1800, 1801. Different sorts of, 1802—1808. Patent slating, 1809.  
 Slater's work, how measured, 2370.  
 Slater's work, in specifications, 2283.  
 Slates, proper slope of roofs for, 2030.  
 Slating, 2209—2211.  
 Slating, patent, 1809.  
 Slaughter houses. See "Abattoirs."  
 Sleaford, parochial church at, 398.  
 Sleepers and planking, how measured, 2331.  
 Small cut brads, glazier's, 2226.  
 Smithery and ironmongery, 2253—2263.  
 Smith's and ironmonger's works, method of estimating, 2375.  
 Smith's work, in specifications, 2286.  
 Smithson, Huntingdon, engaged on Wollaton Hall, 443.  
 Smithson, Robert, architect connected with building Wollaton Hall, 440, 443.  
 Soils best for foundations, 1882, 1883.  
 Solar cell of the baths of Caracalla, 235.

Sive Florilegium e lusibus poeticis diversorum Oxoniensium Græcis et Latinis decerptum. Curante GULIELMO LINWOOD, M.A. Ædis Christi Alummo. 8vo. 14s. cloth.

**LITTON.—THE CHURCH OF CHRIST,**

In its Idea, Attributes, and Ministry: With a particular reference to the Controversy on the Subject between Romanists and Protestants. By the Rev. EDWARD ARTHUR LITTON, M.A., Perpetual Curate of Stockton Heath; and Vice-Principal of St. Edmund Hall, Oxford. 8vo. 16s. cloth.

"This volume is written in particular reference to the controversy on the subject named in the title-page, which exists between Romanists and Protestants....The antagonism of Rome is upheld by men of learning, and it requires to be met by men similarly qualified. As aid towards attaining such qualification, Mr. Litton's work will be found of great use; and its tone is one of moderation and earnestness. It will be found to such an inquirer and thinker a CHURCH AND STATE GAZETTE.

**LORIMER.—LETTERS TO A YOUNG MASTER MARINER**

On some Subjects connected with his Calling. By the late CHARLES LORIMER. New Edition. Fcp. 8vo. 5s. 6d. cloth.

**NEALE.—THE RICHES THAT BRING NO SORROW.**

By the Rev. ERSKINE NEALE, M.A., Rector of Kirton, Suffolk; Author of "The Closing Scene," &c. Fcp. 8vo. 6s. cloth.

"The excellent object of this little work is to shew how worthless riches are as a means even of temporal happiness, when not used by their possessor as a trustee only for the good of his poorer and less fortunate brethren. This moral is worked out by strong contrasting sketches, such as Wood, of Gloucester, as contrasted with Hetherington, the blind man's hope; Lord Hertford, the sensualist, and Bryan Blundell, the friend of the merchant seamen at Liverpool; Morgan Jones, the miser curate of Llandoverly, and Bancroft, the benefactor of the aged. The work is replete with curious and instructive anecdotes, and is as pleasant to read as profitable to think on." BRITANNIA.

**NEALE.—THE EARTHLY RESTING PLACES OF THE JUST.**

By the Rev. ERSKINE NEALE, M.A., Rector of Kirton, Suffolk; Author of "The Closing Scene," &c. With Wood Engravings. Fcp. 8vo. 7s. cloth.

For the Waistcoat-pocket. A Guide to the Meaning, Quality, and right Accentuation of Latin Classical Words. By the Rev. J. E. RIDDLE, M.A. New Edition. Royal 32mo. 4s. bound.

*RIDDLE AND FREUND'S NEW LATIN DICTIONARY.*

A Copious Latin-English Dictionary; Founded on Andrews's Translation of Freund's larger Latin-German Dictionary: With Improvements and Additions. By the Rev. J. E. RIDDLE, M.A., and Dr. W. FREUND. [In preparation.]

\*.\* The American Latin-English Dictionary by Dr. Andrews is a translation of the Latin Dictionary of Dr. Freund, who is now resident in London, and is occupied, in conjunction with Mr. Riddle, in making a thorough revision of his valuable work, with important additions, in order fully to meet the wants of our colleges and schools, and to give to our more mature scholars those aids which they are entitled to receive in the present advanced stage of philological research. Eighteen years have elapsed since Dr. Freund published a large portion of the Dictionary which Dr. Andrews has translated. During a great part of that interval, Dr. Freund has been actively engaged in preparing a second edition of his elaborate work, which will shortly be published in Germany; and in the course of this undertaking, he has employed materials of which, to say the least, no use has been made by Dr. Andrews. The present work will therefore present to the English student extensive results of modern criticism, which have not hitherto been collected in any single volume.

*RIVERS.—THE ROSE-AMATEUR'S GUIDE;*

Containing ample Descriptions of all the fine leading varieties of Roses, regularly classed in their respective Families; their History and mode of Culture. By T. RIVERS, Jun. New Edition, corrected and improved. Fcp. 8vo. 6s. cloth.

**TATE.—EXERCISES ON MECHANICS AND NATURAL PHI-**

LOSOPHY; or, an Easy Introduction to Engineering. Containing various Applications of the Principle of Work: the Theory of the Steam-Engine, with Simple Machines Theorems and Problems on Accumulated Work, &c. New Edition. 12mo. 2s. cloth.

**TATE.—KEY TO TATE'S EXERCISES ON MECHANICS AND**

NATURAL PHILOSOPHY. Containing full Solutions of all the unworked Examples and Problems. 12mo. with Diagrams, 3s. 6d. cloth.

"This little volume is, like all that Mr. Tate does, remarkable for its lucid arrangement, and the happy way in which a practical bearing is given to the subjects. It contains neat and excellent solutions to all the unsolved questions in his *Exercises on Mechanics*, as well as to some very instructive additional problems; and it will be found invaluable to the unassisted student, as well as to the teacher whose time is of importance." JOURNAL OF EDUCATION.

"Mr. Tate's book gives in a practical and popular form the substance of every mechanical principle, whether belonging to engineering operations; and in order that the student may be enabled to follow the solutions of the examples, the solutions of which are given in the book, the greatest assistance, and the number of examples worked will serve to make the calculations perfectly obvious." MORNING ADVERTISER.

**TATE.—ON THE STRENGTH OF MATERIALS;**

Containing various original and useful Formulae, specially applied to Tubular Bridges, Wrought Iron and Cast Iron Beams, &c. By THOMAS TATE, of Kneller Training College, Twickenham; late Mathematical Professor and Lecturer on Chemistry in the National Society's Training College, Battersea; Author of "Exercises on Mechanics and Natural Philosophy." 8vo. 5s. 6d. cloth.

**TAYLER.—LADY MARY;**

Or, Not of the World. By the Rev. CHARLES B. TAYLER, Rector of St. Peter's, Chester; Author of "Margaret, or the Pearl," &c. New Edition; with a Frontispiece engraved by J. ABSOLON. Fcp. 8vo. 6s. 6d. cloth.

**TAYLOR.—LOYOLA: AND JESUITISM IN ITS RUDIMENTS.**

By ISAAC TAYLOR, Author of "Natural History of Enthusiasm," &c. Post 8vo. 10s. 6d. cloth.

*TAYLOR.—WESLEY AND METHODISM.*

By ISAAC TAYLOR, Author of "Natural History of Enthusiasm," &c. With a Portrait of Wesley, engraved by W. Greatbach. Post 8vo. Hal -a-Guinea, cloth.

“ This volume will be acceptable to the public on many grounds. It will please the religious by its respect for religion and the literary by the force of its style. It will not displease the Churchman by any violence of view, nor the Sectary by any bitterness of language. On the whole, it will perhaps be most welcomed by the philosopher, for its attempt to reconcile opposite perceptions of belief, to account for conflicting opinions, and to show that there is something in the strong and the weak of all religions, and that the true religion will be in the end the strongest, and the most attractive by its own merits.”

BRITANNIA.

*THIRLWALL.—THE HISTORY OF GREECE.*

By the Right Rev. the LORD BISHOP of ST. DAVID'S (the Rev. Connop Thirlwall). An improved Library Edition; with Maps. 8 vols. 8vo. £4. 16s. cloth.

\*.\* The above works, which were prepared under the superintendence of the Society for the Diffusion of Knowledge, are now published by Messrs. Longman and Co., by assignment from Mr. Charles Knight. It is to be observed that the edition of Mr. Youatt's book on the Horse which Messrs. Longman and Co. have purchased from Mr. Knight, is that which was thoroughly revised by the author, and thereby rendered in many respects a new work. The engravings, also, were greatly improved. Both works are the most complete treatises in the language on the History, Structure, Diseases, and Management of the Animals of which they treat.

**ZINCKE.—SOME THOUGHTS ABOUT THE SCHOOL OF THE**

FUTURE; Or, a Sketch of the Solution which Time appears to be preparing for the different Educational Questions of the Day. By the Rev. FOSTER BARHAM ZINCKE, Vicar of Wherstead, near Ipswich. Post 8vo. 7s. cloth.

"Mr. Zincke has, in the course of a few pages, supplied us with a large amount of matter, and supported his arguments by a variety of facts, both ancient and modern. We and others who advocate a great and liberal education, and who have been hitherto somewhat sceptical as to the value of the present system, are much interested in the questions which he discusses. We certainly cannot but be struck by the force of his reasoning, and we should be glad if we could give sufficient space to a full discussion of the arguments and illustrations which he presents. We cannot do this, we must be content with a few remarks on the general merits of his views. His views are on the whole just, liberal, and comprehensive, and he has the great merit of saying much in few words. We have, indeed, seldom met with so much important matter condensed into so small a space. Almost every topic that the consideration of such a question includes is touched upon by the author, and yet the whole volume contains only 235 pages, and of this number 76 are occupied by an appendix, which is by no means the least interesting or important part of the work." CHRISTIAN TIMES.

**ZUMPT'S GRAMMAR OF THE LATIN LANGUAGE.**

Translated and adapted for the use of English Students, with the Author's sanction and co-operation, by Dr. L. SCHMITZ, F.R.S.E., Rector of the High School of Edinburgh: with copious Corrections and Additions communicated to Dr. Schmitz by Professor ZUMPT. New Edition, corrected. 8vo. 14s. cloth.
